Luxation of the Acromion. K. BÜDINGER.—Luxatio claviculæ acromialis is difficult to reduce and hold in position. Sutures of the bones frequently fail to maintain them in a correct position. Büdinger has been unfailingly successful with his method, which consists in boring with his longest and strongest drill directly through the acromion and lengthwise into the clavicle—the bones held in normal position until it has entered a distance of 5 cm. The rest of the apparatus is then taken off and the drill left in the bone for eighteen days, when it is removed, with the conditions permanently restored to normal.

Emigration of Calculi. R. PORGES.—The mother of a colleague had suffered from a fistula in the thigh for one and one-half years. She was a healthy woman, 47 years of age, with no antecedents except a record of severe biliary lithiasis at one time, with symptoms of febrile cholecystitis, requiring seven weeks' stay in bed, and pains in the cecal region persisting for a time, followed a year or so later with a tumor in the thigh, very painful, which terminated in the rebellious fistula. The operation on the latter showed that the upper portion of the thigh was traversed by a network of passages in which a large number of biliary calculi were found. The attack of cholecystitis four years before had evidently terminated with the rupture of the gall-bladder and escape of the calculi, which had worked downward, during the long stay in bed, to the back and thence down into the thigh. In 169 cases of wandering calculi collected by Courvoisier, the fistula opened in the right iliac region in 12; in the left in 1; below the navel in 11; in the navel in 12. and in the bladder in 1. Huguier has reported a case of multiple fistulæ opening in the hypogastrium, mons veneris and near the clitoris, following a fall on a beam, affecting the liver region.

Wiener Medicinische Blatter, May and June.

May 3.

Early Diagnosis of Carcinoma. A. WAGNER.—When a gastric affection does not improve under general medical and dietetic treatment, and symptoms suggest a malignant lesion, the surgeon should be called in and an exploratory incision made. The mere incision has frequently a beneficial effect in relieving the disturbance.

May 10.

Uric Acid in Nervous Diseases. J. HIRSCHKRON.—Whenever he notes an excess of uric acid in nervous diseases, Hirschkron devotes his attention to its elimination as the chief factor in treatment. He relates numerous instances in which neuralgia, myalgia, rheumatic and arthritic affections were very much improved merely by a course of Salvator water alone.

St. Petersburger Medicinische Wochenschrift, June 23.

Clinical Value of Cryoscopy. O. MORITZ.—In this article, concluded from the preceding number, extensive tests of the freezing-point of the urine as a means of diagnosis are reported. They demonstrate that cryoscopy is a simple, easy and reliable test for the urine. The results coincided in every case with those of more elaborate microscopic and chemical tests.

Semana Medica (Buenos Ayres), May 10.

Unconscious Parturition. G. SERRA.—The writer relates three cases of childbirth which occurred in healthy women without their knowledge, until apprised by the cry of the child. One case was Serra's own daughter. She complained of moderate pain in the abdomen one night, and he gave her a sedative on her assurance that they could not be labor pains as her time had not arrived. She complained a few minutes later of severe pain in the genital region and, on examination it was found that a fetus had just been expelled. Its foot catching in the cervix had caused the local pain.

Gazzetta degli Ospedale (Milan), June 24.

Tuberculous Toxemia. E. MARAGLIANO.—Certain symptoms in tuberculosis indicate the action of toxins, but the existence of the toxins has never yet been scientifically verified. Maragliano has filled this gap in our knowledge of the disease by a series of experimental tests on guinea-pigs and other small animals, and has conclusively demonstrated that the fresh blood, the glycerinated extract of the blood and the precipitate of the urine, in persons affected with tuberculosis, have a toxic action on both sound and tuberculous animals, as manifested by the familiar clinical phenomena. His research also showed that these toxins can be neutralized by tubercular antitoxin.

Arteriosclerosis of Myocardium. G. BERGHINZ.—An infant, 18 months old, died suddenly in the midst of apparent health, with sudden, paroxysmal dyspnea, accompanied by a spasmodic cough and intense cyanosis, with transient symptoms of edema of the lung, but no fever nor renal symptoms, nor indications of convulsions, laryngeal spasm nor of the habitus thymicus. The autopsy disclosed the typical lesions of congenital syphilides, localized chiefly on the myocardium in the form of arteriosclerosis of the heart. No syphilitic history on the part of the parents could be learned. The same syndrome and lesions were observed in a similar case in which the syphilitic antecedents of the father were proved beyond question. The *Cbl. f. Kindhk.* for June contains a summary of twenty-two cases of hereditary syphilis affecting the automatic ganglia of the heart, showing the possibility of interstitial myocarditis from proliferation of the connective tissue of perivascular origin, as in the observations described above.

Massage for Fractures. L. TAVECCHI.—The modern treatment of fractures of the leg without immobilization is rational, according to Tavecchi, and has afforded brilliant results from every point of view in his experience, with prompt intervention with massage, passive and active movements and baths of hot sand. Histology has confirmed the results attained in the clinics, showing that muscles after a trauma present evidences of diffuse sclerosis with hypertrophy of the adjacent connective tissue, interstitial hemorrhage, engorgement of the blood-vessels and hypertrophy of their external cellular coat. On the other hand muscles massaged after a trauma are of normal aspect. There are also evidences of neuritis and perineuritis in the first case which are entirely absent in the second. The articulation also "grows rusty" from disuse.

Queries and Minor Notes.

CONTRACT PRACTICE.

ATHENS, ILL., July 9, 1900.

To the Editor.—The enclosed clipping from a local paper shows how it is done in Menard County, Ill., in these last days of the 19th century. The physicians of the various precincts are asked by the County Board to name a lump sum for which they will agree to furnish to the pauper poor of their respective precincts medical and surgical attendance, medicines, drugs, etc., for the year. Pauper poor is understood to mean all those who are dependent on the county. My position is that it is unethical for a physician to enter into such a contract. Am I right in this? M.D.

The following is the notice referred to by our correspondent:

"Bids for Medical Practice.—The County Board of Menard County will receive bids for the pauper medical practice of Athens precinct for one year, at its regular July session at the county court house on the second Monday of July. M. H. LEVERING, Clerk."

ANSWER:—Whether ethical or not, it is certainly foolish for a physician to lower himself and his profession by noticing such a demand by public officials. If the physicians of Menard County were organized as they should be, and stood together as they ought to do, the County Board would pay a fair sum for the services rendered.

REQUIREMENTS FOR PRACTICE.

EVANSVILLE, IND., July 3, 1900.

To the Editor.—Will you kindly inform me regarding the requirements for the practice of medicine in Nebraska and Michigan, and give me the address of the Secretary of each State Board of Health?

How and where can one get a report of the Illinois State Board of Health for 1898? P. R.

ANSWER:—In Nebraska a certificate is required and no one can obtain it unless he is a graduate of a legally incorporated medical college in good standing, requiring attendance on four courses of lectures in four separate years. There is no examination. The fee for the certificate is $5.00. The Secretary of the Board is Dr. F. Crummer, Omaha. In Michigan, a diploma from a medical college approved by the State Board of Registration or an examination will be required. The Secretary is Dr. B. D. Harison, Sault Ste. Marie, who will furnish blank forms and other details.

Write Dr. J. A. Egan, Springfield, Ill., for copy of Report of Illinois State Board of Health.

BLUE HILL, NEB., July 10, 1900.

To the Editor.—Will you please inform me as to the law governing the practice of medicine in Georgia? W. C. F.

ANSWER:—To obtain a diploma to practice medicine in Georgia an examination is required before one of the State Boards of Health of the three principal schools of medicine, and the applicant has to show that he has a diploma from an incorporated school requiring not less than three full courses of study of six months, unless his diploma dates prior to 1895, when two full courses may be sufficient. The Secretary of the Board of Registration is Dr. J. B. S. Holmes, Atlanta. The fee is $10.

The Public Service.

Navy Changes.

Changes in the Medical Corps of the U. S. Navy for the week ending July 14, 1900.

P. A. Surgeon F. W. Olcott, detached from the recruiting rendezvous, Philadelphia, Pa., and ordered home and granted sick leave for two months.

P. A. Surgeon W. B. Grove, detached from the *Scindia* and ordered home.

Surgeon W. H. Rush, granted sick leave until October 1.

Marine-Hospital Changes.

Official list of the changes of station and duties of commissioned and non-commissioned officers of the U. S. Marine-Hospital Service for the seven days ending July 12, 1900.

Surgeon G. W. Stoner, granted leave of absence for five days.

Surgeon A. H. Glennan, detailed as quarantine officer at the port of Havana, Cuba, vice Surgeon H. R. Carter, relieved.

Surgeon Eugene Wasdin, granted leave of absence for 10 days.

Surgeon L. L. Williams, detailed as acting medical purveyor during the absence on leave of Surgeon G. W. Stoner.

Surgeon W. P. McIntosh, granted extension of leave of absence for two days.

P. A. Surgeon Rupert Blue, directed to proceed to Milwaukee, Wis., and assume command of the Service, reporting at Washington, D. C., en route.

P. A. Surgeon E. K. Sprague, granted leave of absence for two days.

Asst.-Surgeon S. B. Grubbs, detailed to represent the Service at the Fourth Session of the International Congress of Applied Chemistry at Paris, France.

Asst.-Surgeon W. C. Billings, relieved from duty at Washington, D. C., and upon expiration of leave of absence, to proceed to Baltimore, Md., and report to medical officer in command for duty and assignment to quarters.

Asst.-Surgeon J. W. Kerr, relieved from temporary duty at San Francisco quarantine, and directed to proceed to Honolulu, H. I., and report to Surgeon Carmichael for duty.

Asst.-Surgeon F. J. Thornbury, on return of P. A. Surgeon C. H. Gardner from leave of absence, to proceed to Chicago, and report to medical officer in command for duty and assignment to quarters.

Asst.-Surgeon C. W. Vogel, relieved from duty at San Francisco quarantine, and directed to proceed to San Francisco and report to medical officer in command for duty and assignment to quarters.

Asst.-Surgeon M. W. Glover, on being relieved from duty at Baltimore, Md., directed to proceed to Boston, Mass., and report to medical officer in command for duty and assignment to quarters.

Asst.-Surgeon B. H. Earle, directed to proceed to Cape Nome, Alaska, for special temporary duty.

Asst.-Surgeon C. C. Pierce, relieved from duty at Mobile, Ala., and directed to proceed to Tortugas quarantine and report to medical officer in command for duty and assignment to quarters.

Acting Asst.-Surgeon L. P. Gibson, granted leave of absence for five days.

APPOINTMENT.

A. G. Greenstreet, of the District of Columbia, appointed acting asst.-surgeon for duty at Wilmington, N. C., July 11, 1900.

Health Reports.

The following cases of smallpox, yellow fever, cholera and plague have been reported to the Surgeon-General, U. S. Marine-Hospital Service, during the week ended July 14, 1900.

SMALLPOX—UNITED STATES.

District of Columbia: Washington, July 1-7, 4 cases.
Florida: Jacksonville, July 1-7, 1 case.
Illinois: Cairo, July 1-7, 7 cases.
Indiana: Evansville, July 1-7, 1 case.
Iowa: Des Moines, June 1-30, 3 cases.
Kansas: Wichita, July 1-7, 9 cases.
Kentucky: Covington, July 1-8, 13 cases.
Louisiana: New Orleans, July 1-7, 18 cases, 5 deaths.
Maryland: Cumberland, July 1-7, 5 cases.
Massachusetts: Fall River, July 2-9, 2 cases.
Michigan: Jackson, July 1-7, 1 case.
Minnesota: Minneapolis, June 8-30, 20 cases, 1 death.
Nebraska: Omaha, June 23-30, 3 cases.
New Hampshire: Manchester, July 1-7, 1 case.
New York: New York, July 1-7, 1 case.
Ohio: Cincinnati, June 30 to July 6, 6 cases; Cleveland, July 1-7, 37 cases.
Pennsylvania: Pittsburg, July 1-7, 1 case.
Utah: Ogden, June 1-30, 6 cases; Salt Lake City, July 1-7, 1 case.
Virginia: Roanoke, June 1-30, 22 cases, 1 death.
Washington: Tacoma, June 23-30, 1 case.
West Virginia: Charlestown, July 7, 4 cases.

SMALLPOX—FOREIGN AND INSULAR.

Austria: Prague, June 16-23, 5 cases.
Egypt: Cairo, June 10-17, 1 case.
England: Liverpool, June 16-23, 1 case; London, June 16-23, 13 cases.
France: Bordeaux, May 1-31, 1 death; Paris, June 16-23, 1 death.
Greece: Athens, June 16-23, 10 cases, 6 deaths.
India: Karachi, June 3-10, 8 cases, 7 deaths; Madras, May 26 to June 1, 1 death.
Mexico: Chihuahua, July 1-7, 1 death; Vera Cruz, June 23-30, 5 deaths.
Philippines: Manila, May 19-26, 1 case.
Porto Rico: Ponce, June 8-23, 1 case.
Russia: Moscow, June 8-16, 19 cases, 2 deaths; Odessa, June 16-23, 2 cases, 1 death; St. Petersburg, June 16-23, 27 cases, 11 deaths; Warsaw, June 8-16, 2 deaths.
Straits Settlements: Singapore, May 19-26, 1 death.

YELLOW FEVER.

Colombia: Barranquilla, June 16-23, 7 cases, 3 deaths; Cartagena, June 14-21, 5 cases, 5 deaths; Panama, June 25 to July 2, 1 death.
Cuba: Havana, June 20-30, 3 deaths; Santa Clara, June 20-25, 4 cases.

CHOLERA.

India: Madras, May 26 to June 1, 2 deaths.

PLAGUE—FOREIGN AND INSULAR.

Egypt: Port Said, April 20 to June 18, 75 cases, 32 deaths.
India: Karachi, June 3-10, 13 cases, 13 deaths.
Japan: Osaka, June 2-12, 6 cases; Shidzuoka Ken, June 2-12, 2 cases.
Philippines: Manila, May 12-26, 7 cases, 4 deaths.
Turkey: Smyrna, June 6-21, 5 cases.

Change of Address.

Dr. C. P. Aling, from Blue Earth to City Hospital, Stillwater, Minn.

Dr. S. Anderson, from Anaconda, Colo., to Collins, Wyo.

Dr. H. Allison, from 1214 Baxter St. to 323 W. Walnut St., Louisville, Ky.

Dr. Chas. Anderson, from Santa Barbara, Cal., to Ft. Brown, Brownsville, Texas.

Dr. F. E. Auten, from Ludlow and 5th Sts., Dayton, to Cor. Dowing and Ash Sts., Piqua, Ohio.

Dr. G. R. Baker, from 598 Mitchell St., Milwaukee, to Tomahawk, Wis.

Dr. B. B. Brashear, from Atlantic City, N. J., to Concord, Mass.

Dr. T. J. C. Brennan, from 1714 Fairmount Ave., Baltimore, Md., to Woodhaven, Brooklyn, N. Y.

Dr. L. M. Berg, from 2236 to 2032 Michigan Ave., Chicago.

Dr. L. A. Bolling, from Gen. Delivery to 150 Wells St., Fort Wayne, Ind.

Dr. S. D. Bell, from White River to Tucson, Ariz.

Dr. T. J. Caldwell, from 4658 State St. to 11412 Michigan Ave., Chicago.

Dr. J. E. Claussen, from 2205 Cumings St., Omaha, to 405 Court St., Beatrice, Neb.

Dr. J. A. Collie, from Williams Bay, Wis., to Manila, P. I.

Dr. Coryell Faulkner, from 807 Kansas Ave., Topeka, Kan., to Station D, Minneapolis, Minn.

Dr. H. Cushman, from Weston, Neb., to 918 Chicago Ave., Minneapolis, Minn.

Dr. J. E. Coyle, from 1522 Broadway to 1531 Broad St., Paducah, Ky.

Dr. L. Carr, from Stony Creek to 15 Victoria Ave. N., Hamilton, Ont., Can.

Dr. A. B. Davenport, from 1449 Franklin Ave. to Franklin and Miller Aves., Columbus, Ohio.

Dr. M. F. Dorsey, from Amboy to Ladd, Ill.

Dr. J. C. Dunn, from 709 Congress St., to 3700 Wallace St., Chicago.

Dr. D. D. Eads, from Paris, Ky., to 683 Washington Blvd., Chicago.

Dr. J. R. Garner, from Charlottesville, Va., to 302 2nd Ave., New York City.

Dr. O. W. Goss, from Laconia to Lakeport, N. H.,

Dr. B. B. Griffith, from 4th and Broadway to 523½ Broadway, Paducah, Ky.

Dr. R. C. Hefelbower, from Berkshire Bldg. to 22 W. 7th St., Cincinnati, Ohio.

Dr. Lee Haynes, from Unionville to Mendota, Mo.

Dr. I. M. Houston, from Stanberry, Mo., to Falls City, Neb.

Dr. J. W. Ingalls, from 848 to 874 Lafayette Ave., Brooklyn, N. Y.

Dr. J. L. Jarvis, from Calhoun to Corner Walker and Peters Sts., Atlanta, Ga.

Dr. Elmer Lee, from 52 to 9 West 45th St., New York City.

Dr. Miss J. Lyons, from 898 Jackson Blvd., Chicago, to Hume, Ill.

Dr. T. W. Morgan, from Dawson to Lowder, Ill.

Dr. M. M. Martinson, from Algona, Iowa, to 34 Hanover St., Battle Creek, Mich.

Dr. E. W. Meis, from Zwingle to Dyersville, Iowa.

Dr. E. J. Musselem, from 278 Michigan Ave. to 2502 Wentworth Ave., Chicago.

Dr. P. A. McIlhenny, from 1423 Louisiana Ave., New Orleans, La., to 513 Dearborn Ave., Chicago, Ill.

Dr. C. C. Owens, from Maysville to Feeble-Minded Institute, Frankfort, Ky.

Dr. W. L. Pyle, from 1831 to 1806 Chestnut St., Philadelphia.

Dr. S. G. Pake, from West Duluth, Minn., to 1303 Tower Ave., West Superior, Wis.

Dr. A. H. Peters, from Hillsdale, Ill., to Princeton, Iowa.

Dr. F. M. Pickens, from Winfield, Kansas, to Box 211, Indianapolis, Ind.

Dr. Rose A. Russell, from 339 S. Lincoln St. to 32d St. and Rhodes Ave., Chicago.

Dr. H. R. St. John, from 936 Barnett St., Kansas City, to Lost Springs, Kan.

Dr. C. T. Smith, from 30 Grant Pl., Washington, D. C., to Croxton, Va.

Dr. G. E. Shoemaker, from 3727 Chestnut St., Philadelphia, to Eaglesmere, Pa.

Dr. W. K. Scofield, from Cocoa, Fla., to 1217 Filbert St., Philadelpha.

Dr. H. H. Sherk, from 2647 Westfield Ave., Cramer Hill, to Camden, N. J.

Dr. W. E. Shook, from 42 Laflin St., Chicago, to Auburn, Neb.

Dr. B. L. Shellhorn, from 640 Congress St., Chicago, to Peru, Neb.

Dr. J. E. Smith, from 715 Congress St., Chicago, to Flower Creek, Mich.

Dr. E. W. Singletary, from Wilson to Morganza, La.

Dr. J. T. Smith, from 184 Dearborn St. to 65 Washington St., Chicago.

Dr. E. T. Sabal, from 45 to 29 W. Monroe St., Jacksonville, Fla.

Dr. J. M. Tirrell, from Minneapolis, Minn., to Portal, N. D.

Dr. S. M. Taff, from 2600 Pine St. to City Hospital, St. Louis, Mo.

Dr. E. L. Tompkins, from 1512 Q St., Washington, D. C., to Pine Creek Mills, Va.

Dr. C. C. Tallman, from 19 Ashland Blvd., Chicago, to Keota, Ia.

Dr. R. C. Turck, from 2346 Dearborn St. to 452 E. 49th St., Chicago.

Dr. Z. Wilson, from 742 Jackson Blvd.,, Chicago, to Pennsboro, W. Va.

Dr. N. W. Webber, from 535 Woodward Ave. to 26 Lathrop Ave., Detroit, Mich.

Dr. W. J. Webb, from Kirksville, Mo., to Martinton, Ill.

Dr. John H. J. Upham, from 1414 to 106 E. Broad St., Columbus, Ohio.

THE JOURNAL OF THE
AMERICAN MEDICAL ASSOCIATION

61 Market Street : : Chicago, Ill.

Cable Address: "Medic, Chicago"

Subscription price: Five dollars per annum in advance

Postage in the United States and Canada, Mexico, Hawaii, Guam, Porto Rico, and the Philippines, free; foreign postage, $2.50. Subscriptions may commence at any time. Volumes begin with the first issue of January and of July.

MEMBERSHIP IN THE AMERICAN MEDICAL ASSOCIATION.

The qualifications for membership require that the applicant be a member, in good standing, of a state or local medical society entitled to send delegates to the annual meeting of the American Medical Association. A list of these societies will be sent on request. Applications must be accompanied with a certificate showing that the applicant is a member of a recognized society, and should be sent with the annual dues—*five dollars*—to the treasurer, Dr. Henry P. Newman, 100 Washington Street, Chicago. Members receive The Journal free. Subscribers to The Journal may become members of the Association without additional expense if they are members of medical societies recognized by the Association. Those desiring to have their names transferred from the subscription to the membership lists should send certificates as above, with a receipt for their subscription to The Journal, covering the current fiscal year.

FISCAL YEAR.

The fiscal year of the American Medical Association is from January 1 to December 31; and the annual dues paid by a new member cover only the fiscal year, no matter at what time of year the membership is obtained. Those who pay their dues and join the Association at the annual meeting in June, for instance, pay only for the fiscal year which ends with the December following, and the annual dues for the following fiscal year are payable the succeeding January, at which time the treasurer sends a statement to each member. Such members, however, are entitled to The Journal for the full year, even though the membership be not continued.

PAPERS READ AT THE ANNUAL MEETING.

"Every paper received by this Association and ordered to be published, and all plates or other means of illustration, shall be considered the exclusive property of the Association. . . The Board of Trustees shall have full discretionary power to omit from the published transactions, in part or in whole, any paper that may be referred to it by the Association or either of the Sections, unless specially instructed to the contrary by vote of the Association." (*From Article V of the By-laws.*)

NEWS.

Our readers are requested to send us items of news of a medical nature, also marked copies of local newspapers containing matters of interest to members of the medical profession. We shall be glad to know the name of the sender in every instance.

ORIGINAL PAPERS.

Articles are accepted for publication with the understanding that they are contributed solely to this journal.

COPYRIGHT.

Matter appearing in The Journal of the American Medical Association is covered by copyright, but as a general thing, no objection will be made to the reproduction of anything appearing in its columns if proper credit be given.

CONTRIBUTIONS TYPEWRITTEN.

It will be satisfactory to all concerned if authors will have their contributions typewritten before submitting them for publication. The expense is small to the author—the satisfaction is great to the editor and printer. We can not promise to return unused manuscript.

Half-tones, zinc etchings and other illustrations will be furnished by The Journal when photographs or drawings are supplied by the author.

ADVERTISEMENTS.

Advertising forms go to press eight days in advance of the date of issue. Therefore, in sending in copy, time should be allowed for setting up advertisements and for the sending and return of proofs. Advertising rates will be made known on request.

CHANGE OF ADDRESS.

In ordering a change of address it is important that both the old and new addresses be given.

REMITTANCES.

Remittances should be made by check, draft, registered letter, money or express order. Currency should not be sent, unless registered. Stamps in amounts under one dollar are acceptable. Make all checks, etc., payable to "Journal American Medical Association," except those for annual dues. These should be made payable and sent direct to the Treasurer, Dr. Henry P. Newman, 100 Washington Street, Chicago.

THE ANGIOTRIBE IN ABDOMINAL SURGERY.*

HUGH M. TAYLOR, M.D.
RICHMOND, VA.

In the summer of 1899, it was my privilege to see the angiotribe used by Dr. Cleveland, of New York. This demonstration and the interesting paper in which he impressed the advantages of the angiotribe, its *modus operandi*, its technique, and the very satisfactory results attending its use by himself and others, prompted me, as soon as possible, to obtain an angiotribe and to use it in selected cases.

A precaution, impressed by Dr. Cleveland, was borne out by my first experience in ordering an angiotribe. The first instrument I received was found sprung and imperfect, after having been used only once or twice. To stand the great strain upon it, fine workmanship in constructing the angiotribe is essential. We saw Dr. Cleveland break an instrument he was using, and this suggests the advisability of providing oneself with more than one angiotribe. The cost of the angiotribe—$18—is an item in the first instance, but this should not be considered, if by its use the safety of the patient is in the least conserved. Moreover, the angiotribe can probably be used indefinitely and its original cost will not exceed in the long run, the outlay for ligatures and forceps.

My experience with the angiotribe has been limited to twenty-five or thirty cases, all of which were suprapubic sections. I have in no instance used it when operating by the vaginal route. This is largely due to the fact that I have had but a limited experience in working through the vagina. The encouraging reports from so many warrant the conclusion that the angiotribe is equally serviceable as a hemostatic means in intrapelvic work per vaginam.

A majority of my cases were very simple in character, about one-half were uncomplicated hysterectomies, while the other represented a variety of ovarian cystomas, morbid conditions of the tubes, etc. In only one instance were there post-operative symptoms which suggested the occurrence of hemorrhage. This case was a large ovarian cystoma, with extensive bowel adhesions, and the trauma was considerable; the post-operative shock was quite profound and lasting. In one case there was for several days sufficient febrile reaction, etc., to make me fear sepsis. This was also a large cystoma, but was non-adherent, and nothing occurred during the operation to induce infection, unless there was some escape of the cyst contents into the peritoneal cavity. In connection with this case I may say I felt no little satisfaction in knowing that there was no intraperitoneal ligature to add to the danger. At the same time I must confess, in not a few instances, to some sense of insecurity as to the probability of hemorrhage for the first few hours after the operation. This fear of hemorrhage, however, after having used the angiotribe, is not greater than my fear of infection from the use of intraperitoneal suture or ligature. I have not used the angiotribe in many septic cases, but it is especially desirable to avoid the use of the ligature in existing or threatened septic conditions. In only one instance have I failed to secure complete hemostasis by means of the angiotribe. This occurred in resecting a section of badly-infected and thickened omentum, which had wrapped up a necrotic appendix. This experience impresses the idea that the soft omental tissue will cut through, rather than condense, under powerful pressure.

My limited experience sustains fully the advantages claimed for the angiotribe. In selected cases, I think it a perfectly safe substitute for ligatures and compression forceps. The ribbon-like line of compressed tissue left in the pelvis or abdomen looks very much better to me than the mass grasped by either forceps or ligature. By means of the angiotribe the tissues are compressed for only a few minutes; tissue necrosis is said not to occur; microscopic examinations demonstrate that the ribbon of compressed tissue is quickly revivified.

The tissues grasped by the forceps are strangulated for from twelve to twenty-four hours, while that in the loop of even the absorbable ligature is constricted for days. With the angiotribe there is no puckering and traction, as is the case not infrequently with the ligature applied en masse.

The precautions incident to the application of the angiotribe—at right angles to the blood-vessels and for three minutes—are so simple that its use would seem especially indicated by those who, from lack of experience, have not mastered the art of applying ligatures to structures in the abdomen and pelvis.

I have been duly impressed with the quite commonly observed fact that post-operative shock is markedly diminished in the cases in which the angiotribe was used, and this I think is equally true as to the intensity and duration of post-operative pain. Convalescence seems, as a further sequence, to be established at an earlier date and to progress more rapidly.

The query very naturally arises, "Is there a need for this innovation?" (If it can be said, strictly speaking, to be an innovation; for a long time instruments designed to act upon the same precept as the angiotribe have been in use, notably clamps, snares, écraseurs, etc.; Tuffier's angiotribe is merely a more perfect instrument.) With the recent evolution of the absorbable aseptic ligature in an aseptic field, have we anything more to desire? Undoubtedly, our ability to provide an absorbable aseptic ligature in a sufficiently aseptic field has immensely widened the scope of operative intervention, but unfortunately in many instances we can not secure an aseptic field, and not infrequently, in spite of our best efforts, even the absorbable ligature infects before it is absorbed. In my own experience, in more than one instance, I have been tormented beyond description by a dead silk ligature in the pelvis. One of the worst cases of wound infection I have ever met with occurred in connection with an Alexander operation in which I used Marcy's kangaroo tendon. Prior to this catastrophe, I had used this suture material in perhaps a dozen or more Alexander operations with perfectly satisfactory results.

---

*Presented to the Section on Obstetrics and Diseases of Women, at the Fifty-first Annual Meeting of the American Medical Association, held at Atlantic City, N. J., June 5-8, 1900.

Not long since, I lost a patient on whom I did a simple appendectomy for recurring appendicitis. Virulent peritonitis from wound infection, presumably from St. John Leven's chromicized catgut, resulted, and yet I have uniformly, prior to this sad occurrence and since, used this suture material with more confidence than any with which I am familiar. I am conscious of the fact that almost countless avenues of wound infection, other than through the ligatures and suture, present themselves during an operation; it is probably as true that accidental infection of the suture and ligature material is possible in its manufacture; and there is greater possibility of its infection in its preparation for the operator. *In short, until the evolution of the aseptic ligature is further advanced there will occasionally occur*, even in an aseptic field, such disasters as I have instanced; while in a septic field there can be no question as to the great advantage of not having to use even the absorbable ligature and suture.

It is interesting to consider why the ligature was abandoned, prior to its re-introduction by Ambrose Paré, about 1600. Usually Ambrose Paré is credited with having introduced the ligature, but there is abundant evidence to show that he simply re-introduced it, as a substitute for the hot iron, boiling pitch, etc. I say re-introduced, because the ligature probably simply fell into disuse during the dark period of the Middle Ages. Antillus lived in the fourth century. He is credited with the "earliest recorded treatment of aneurysm[1]. The vessel, having been exposed, was tied on each side of the aneurysm, the sac incised and its contents turned out." Observing that contused and lacerated wounds do not bleed as freely as the incised wound, especially in the pre-aseptic era, it was not surprising that the effort should be made to secure hemostasis by compression or torsion.

Torsion was quite extensively practiced in the pre-aseptic era. "In some of the London hospitals—Guy's, I think—it is used almost exclusively instead of the ligature[2]." The late Dr. Murdock, of Pittsburg, only a few years ago, urged the use of torsion in lieu of the ligature, and reported a large number of cases in which it was successfully practiced, many of them major amputations. The wound surface to which the angiotribe is applied is of the nature of a contused and lacerated wound, and Nature's method of arresting hemorrhage, i. e., by contraction, retraction, and clotting, is imitated when the angiotribe is used, and no foreign substance—neither ligature or necrotic substance—is left in the wound to act as an irritant.

1. Am. Text-book of Surgery, p. 242.
2. Cheever: Lectures on Surgery, p. 100.

A NEW periodical has appeared in Germany with the title, "*Blätter zur Bekämpfung des kurpfuscherthums*" or Campaign against Quacks. It is published every fortnight and costs four marks a year. The editors are Echtermeyer and Flatau, Alexandrinen Str. 27, Berlin, S. W.

IMPROVED TECHNIQUE IN MAJOR AND MINOR SURGERY OF THE FEMALE GENERATIVE ORGANS.*

HENRY PARKER NEWMAN, A. M., M. D.
CHICAGO.

It may be said without fear of contradiction that we owe to anesthesia, antisepsis and hemostasis not only the immense advance in modern surgery and its still greater possibilities, but a tendency to loose methods and careless work. This follows so naturally the comparative immunity from danger which surgical patients now enjoy that we need to be constantly on guard against it. With the patient before one on the operating-table, anesthetized, insensate as the raw material under the hand of the artisan and protected from immediate danger by the safeguards of hemostatis and antisepsis there is for some too great temptation to loiter over unessential details, to do showy work or to undertake daring experiments. Also the favorable conditions under which we may operate to-day make it easy to forget that in handling organs or tissues of the body we are dealing with living substances of different degrees of resisting power, and that the success of our maneuvers depends very largely on the amount of delicacy, dexterity and expedition that we use. The least possible violence must be done to delicate structures if we are to approach ideal results. In work within the peritoneal cavity, for instance, it is not enough to do an anatomically correct operation for the removal of this or that lesion of the viscera. Too often after such work we find women suffering as much as before operation. The scar tissue, adhesions and distortions that follow undue violence or careless work are frequently as great a bugbear to the patient as the condition for which the operation was undertaken. This is science overreaching herself, for it goes without saying that the main object of all operative work is to benefit the patient. And particularly is this true of all plastic surgery where a life-and-death emergency does not exist as an excuse for bungling work.

Take for example simple division and curettement of the non-puerperal uterus. I have seen the most rehensible work done here. Tearing, especially about the internal os, is most unfortunate in rapid divulsion, because close approximation of the torn surfaces and healing by primary union is practically impossible. The consequence is the formation of scar tissue about a circular orifice designed physiologically to soften, dilate and contract at the menstrual period. Thus a delicate and important function of the organ is irreparably impaired. Similar results follow the bungling or ill-advised use of the curette, especially within and about the internal os. Too vigorous or careless use of this instrument may result not only in perforation, but also in the most serious disturbance of the delicate function just mentioned. The resulting granulations and scar tissue, perhaps including the entire cervix, are practically beyond remedy, and not only seriously impair the cervical function, but at all times menace stricture with its pathologic sequelæ. Indeed, this entire subject of when and how to use the curette is so important and so pertinent to my subject, that I could well afford it more extended consideration, but as I wish to speak of other procedures, I will only say by way of emphasis that I would judge of a gynecologist not so much by his hysterectomies as by how he does his curettements.

---

*Presented to the Section on Obstetrics and Diseases of Women, at the Fifty-first Annual Meeting of the American Medical Association, held at Atlantic City, N. J., June 5-8, 1900.

If we regard the infections and chronic inflammatory troubles following cervical lacerations in child-bed as evils to be corrected, if we recognize cervical constrictions or stenosis—the unyielding, imperfectly-formed neck with narrowed, tortuous canal—as pathology to be corrected; in short, if we remember that the cervix is the portal leading to the superimposed uterus and adnexa, often the storehouse of infectious germs and in intimate relation with the inflamed, enlarged or displaced structures above, we must change our methods of dealing with this important organ. The operation of a decade ago, still widely practiced, has failed to fulfill the predictions of its early advocates, though entitled to the respect due all conscientious pioneer work. We now know that we can not correct the accrued pathology of an old laceration of the cervix by removing a wedge-shaped mass at either angle and sewing up the wound. You may restore contour to a certain degree, but this is not all that is necessary. To cure the patient, one should aim to correct existing lesions in such a manner as to restore physiologic relations and re-establish normal function. One can not produce a proper and permanent lumen in a defective or ill-developed cervical canal by divulsion alone, except in those cases where pregnancy promptly intervenes. This, however, is a rare exception, as sterility is the rule in such cases, not only on account of the defective channel leading to the uterine cavity, but from the catarrhal endometritis caused by it. A cervical operation, to be successful, must at the same time, in inflammatory conditions, remove all adventitious tissue from the organ, and in deformities or imperfect development, remodel the cervix to as nearly normal outlines as possible, giving ample lumen to the canal and establishing proper menstrual and intermenstrual function. To accomplish these indications I began about six years ago to do some work which I presented to this Section at its Denver meeting under the name "tracheloplasty." The lapse of time has so confirmed its success that I feel justified in outlining it again.

With the patient in the lithotomy position, or in Sims', the cervix is seized and drawn down with an especially designed reversible tenaculum. The cervix is dilated and curetted. The curetting is done only when the indications for its performance exist, but these are so constant as to make it virtually the rule. I now reverse the blades of my tenaculum, directing their points laterally from within outward, thus making traction upon the inner area of the cervix, leaving the anterior and posterior wall free for making the flaps. The cervix is now transfixed by the right-angled knife which I designed for the purpose, and a clean cut made from above downward first in the posterior lip. The anterior lip is transfixed in the same way about 1 cm. or 1.5 cm. in front of the other and cut in the same way. The remaining plug of diseased tissue is now cut away by a single clip or two of the curved scissors, the tenaculum having been changed so as to seize and make traction upon the intervening plug referred to. The flaps now fall together and inward, resembling closely the normal cervix, and a simple method of suture will keep them in this relation. I have modified the manner of placing these sutures by substituting a right-angled curved needle, with handle, as here presented; otherwise the application of these sutures is described and illustrated in The Journal, xxxi, 556. I will only repeat here the advantages which I believe this operation to possess over others. These lie in the certainty and ease with which the flaps can be made with the special knife, the clean-cut surfaces without haggling of tissues, the easy approximation of flaps and prevention of hemorrhage beneath them by deep placing of sutures and compression of flaps; the accurate approximation of mucous membrane to mucous membrane, thus preventing granulating surfaces, formation of cicatrix and constriction of canal. Then we have the certainty of obtaining a permanently patulous canal, with well-formed cervix and pronounced reduction of the hyperplastic uterus. The after-treatment is admirably simple.

In general, all that has been said in regard to cervical work applies with the same force to perineal, and there are the same indications for improvement in technique. To restore contour, stability and function to the weakened pelvic floor, I recommend a method which is the Harris procedure of shortening the torn or stretched fibers of the levator ani muscle, with a slight modification. In all cases of tear into one or both sulci, denude the parts, as in Emmet's perineorrhaphy, namely, by catch forceps upon the crest of the rectocele and laterally along the vaginal orifice as far as we wish to restore the perineum. Put the vaginal mucous membrane on the stretch and map out with the scalpel, and then dissect out a triangular flap along each lateral sulcus. The base of each triangular denudation is toward the vaginal orifice or torn and everted perineal mucous membrane. This latter is also denuded, as in all operations on the perineum. Now dissect out the levator ani muscle at the side of the rectum, seize its anterior fibers and draw on them to see how much slack needs to be taken up in order to hold the rectum and perineal body forward under the pubis. When sufficient of this muscle is free, fold it upon itself in its longitudinal

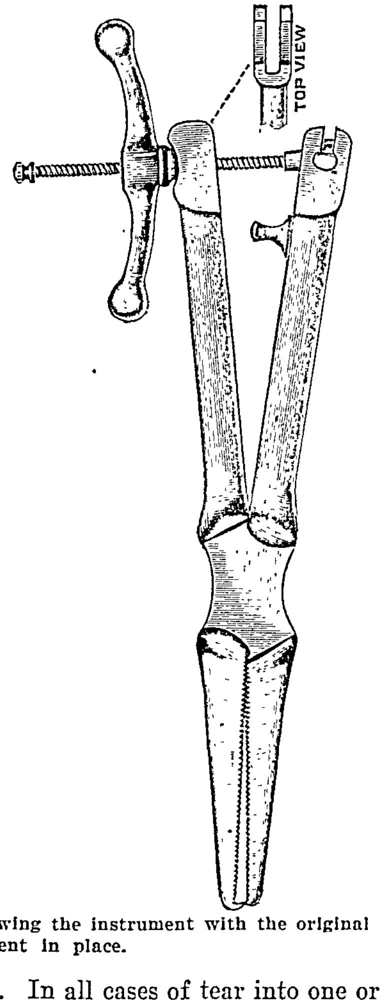

Fig. 1.—Showing the instrument with the original cross-bar and screw attachment in place.

course and stitch the redundant tissue together with interrupted or continuous catgut suture, thus drawing the rectum and perineum well up. The triangular area in each sulcus is now closed with catgut sutures, interrupted or continuous. A buried figure-of-eight—catgut—is now so placed and repeated as to draw the lateral, gaping, perineal surfaces together, and a few superficial silkworm gut sutures close the perineal wound in the median line as in the usual perineorrhaphy.

In rectal and urethral work for hemorrhoids, fistulæ, fissures and carbuncles, the best results can be obtained by clean dissecting out of these lesions and approximating mucous membrane and cut surfaces with catgut, or some less yielding suture material, if preferred. The only objection that can be raised against this procedure is, that in very vascular areas, as about the rectum, there may be considerable bleeding. For this I have lately been using the angiotribe with good results. As vaginal section and vaginal hysterectomy became more popular the technique has been varied and elaborated, and in those familiar with its diversified and perfected execution, the ease with which the uterus can be removed by this route has led to its too frequent performance as a mutilating operation. In its execution the once popular retention clamp has given place to the ligature or some variety of angiotribe or pressure-forceps.

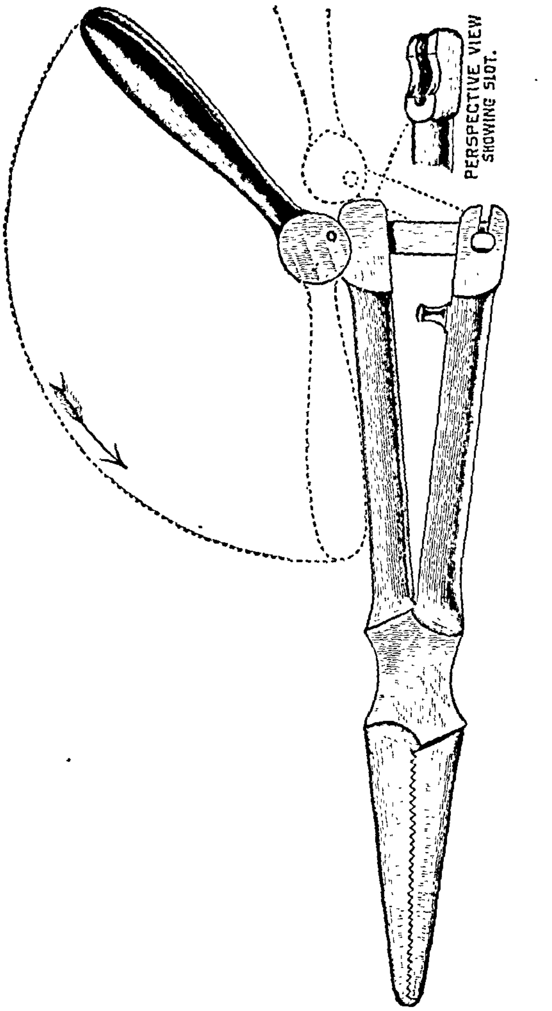

Fig. 3.—Showing the instrument with adjustable lever in place.

This instrument, wherever it has been used to any extent, has made such a favorable impression that I take some pride in the fact that I was the first to introduce it in this country. Dr. Clement Cleveland received the Tuffier instrument January 9 of last year, and performed his first operation on the same day, whereas I arrived from Berlin more than a week before with the Doyen-Thumin modification and presented it to my classes and colleagues in Chicago, which really puts the West several epochs ahead of our New York brethren.

A circumstance connected with my purchase of the model is worth recording. I was in Berlin in December, 1898, and there saw Professor Landau using the angiotribe. Doyen, who disputes honors with Tuffier, had brought it to Berlin and demonstrated it in Landau's clinic. Thumin, an assistant of Landau's, immediately set about making improvements in the mechanism, and it was in its experimental stage that I saw it. Forty-eight hours before my departure I ordered the instrument from the maker. He had none in stock, and demanded an exorbitant price for getting out one in a hurry by special workmen. I objected to the figure, named a reasonable sum, and gave him one day to reflect. Within the specified time the instruments I had ordered, including the angiotribe, were delivered to me. I had no sooner taken ship than a message came to my address from Professor Landau asking for the return of the instrument, as he had no other, and expected to demonstrate it at a clinic the next day. From subsequent correspondence I gathered that the dealers, not to lose a sale, had given me an instrument sent in by Landau or Thumin as a model, or for alterations, and that for the moment I was on the high seas with the only angiotribe outside of France.

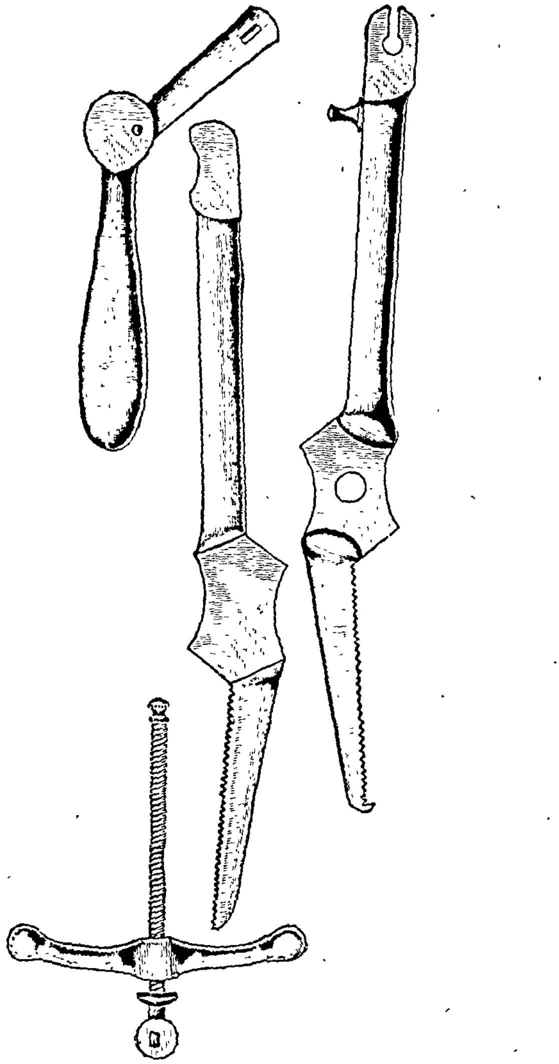

Fig. 3.—Showing the instrument with handles taken apart and its attachments separated.

In studying the mechanism of the instrument, it occurred to me at once that if useful in vaginal hysterectomy, it would be of infinitely more value in abdominal section or within closed cavities. I at once set about making such modifications as I believed would fit it for both abdominal and vaginal work. The changes which I made in the instrument and its use are so fully described in the reports I have already made to the Chicago and American Gynecological societies and this Association at Columbus, that I will only add here a few recommendations which more than a year's experience justifies.

1. It is all important that the instrument itself be of faultless make, and thoroughly tested by a competent mechanic before using. Whatever model is used, the secret of success is in its strength and the accurate adjustment of its blades.
2. Do not use it upon omental or like fragile tissue.
3. Avoid handling or disturbing the attenuated stump after removing the clamp.
4. It is not necessary to cauterize the thin edges of the stump, except when there are infectious germs to be destroyed.
5. As there is no oozing from surfaces amputated in this way, no drainage is required.
6. Compression of 3000 pounds for a minute or more should be practiced in all very vascular areas.
7. In softened, edematous conditions, there is the same danger of cutting and breaking of tissue with the angiotribe as with the ordinary ligature.
8. In applying on pedicles, care should be taken to equally distribute the tissues within the bite of the forceps.
9. The use of the angiotribe requires as much skill and judgment as other and apparently more complicated surgical procedures.

103 State Street.

DISCUSSION ON PAPERS OF DRS. CARSTENS, TAYLOR AND NEWMAN.

[The paper of Dr. J. H. Carstens appeared in The Journal of July 21, p. 159.]

Dr. W. H. Wathen, Louisville, Ky.—I have listened with much pleasure to these interesting papers. I have realized for a long time that much of the objection to surgery of the uterus and its appendages is the result of the multiplicity of technique employed, and the number of instruments used. Very often an operator uses three or four large retractors when they are not necessary. For the last four years I have never performed an operation per vaginam, for pelvic abscesses, uterine cancer, etc., in which I have used more than one retractor. I generally use none at all. Retractors, with few exceptions, are absolutely a nuisance. I use my fingers. Operations upon the cervix, for laceration or amputation, can be done by this means in one-fourth the time required when retractors are used.

As to the angiotribe—I have not used it myself, but I have on many occasions carefully examined the instrument, and I recognize that there is a field for its use. When you make the claim, however, that there is much work that can be done per vaginam by use of the angiotribe that would otherwise have to be done by the abdominal route, I must take issue. I can not conceive of any condition where I could not accomplish as much per vaginam by the use of the clamp as by the use of the angiotribe. With extensive adhesions, the operation by the angiotribe is very much prolonged. In hysterectomy per vaginam for cancer of the uterus we should clamp and divide the broad ligaments outside infected tissue, and this, I have done for many years. I do not think that this could be done so easily and safely with the angiotribe. We often find that it is necessary to apply several clamps in vaginal hysterectomy. In my early surgery I used two; I did bad work. I use many now and do better work. You have to use the angiotribe not only once but possibly four or five times, and I consider that it brings about a very serious complication. In cancer of the uterus, I have always contended that there is no field for abdominal work. When Drs. Kelly and Clark published their methods of operating through the abdomen, I on every occasion denounced the method as illogical. I have no use for it. I claim now, as then, that you seldom have a clamp infection. If you remove them in from 1 to 2½ hours you have certainly committed a great sin against your patient. I believe the vaginal operation is the only rational one; if we wish to be successful let us simplify our technique. The infection first extends between the broad ligaments, later, if ever, into the pelvic or lumbar glands. If the glands are involved, the operation is always contradicted, as I have urged since the operation was first performed.

Dr. J. Riddle Goffe, New York City—I have had considerable experience with the angiotribe, and I wish to say a word for it. It has been said that it simplifies the operation. It certainly does. It is perfectly safe in my opinion. In order to test the efficiency of it I selected for hysterectomy two cases of uterine cancer in which the disease extended out into the broad ligaments. They were strictly inoperable cases, from the standpoint of cure. I used the angiotribe exclusively to control the hemorrhage, and even in cancerous tissues the instrument worked as satisfactorily as in healthy tissue. I not only use it for hysterectomy, but also in removing diseased appendages per vaginam. Quite recently I had a case of cancer of the rectum in which I resected the rectum through the vagina. I made the incision down the posterior vaginal wall, dissected the vagina from the rectum, shelled out the rectum from its bed and dragged it down. As I reached the peritoneal cavity it became necessary to constrict the mesentery, and this instrument, snipping off the mesentery as I went along, acted like a charm, and I had the blood-supply completely under control. Moreover, I pinched the rectum off with the angiotribe, thus controlling hemorrhage from the severed end of the rectum, and obtained a perfectly dry field while stitching it to the margin of the anus. I have used it in cases of hemorrhoids and always found it a perfect hemostatic, easily handled, and convenient. I have been diminishing the time for leaving it on to 1½ minutes. I use the Tuffier angiotribe. I recently reported 16 cases in which I applied it. I have since used it exclusively in all my hysterectomies. It does away entirely with the ligature.

Dr. J. Wesley Bovée, Washington—I am very glad to hear such a good report from the use of this instrument, but it seems to me to be more like a plumber's tool than a surgical instrument. Dr. Carstens says that many operations requiring abdominal section can be subjected to vaginal celiotomy by means of the angiotribe. They could also be done per vaginam without the angiotribe. Many operations could be done through the vagina that are done through the abdomen. It seems to me that, in reaching the peritoneum, the more we work over a membrane constantly exposed to infection, as the vaginal mucous membrane is, the greater is the danger of infecting the patient. We can not expect to have the vaginal mucosa as surgically clean as a towel that we boil and lay over the abdomen in laparotomy. We can not think of such a thing. I think it is wrong to remove tumors per vaginam, pulling them down through a canal which we can not possibly sterilize. Neither can we operate as easily by this route as through the abdomen.

I do not see any reason why these cases operated on with the angiotribe should have a shorter period of convalescence than those operated with the ligature. I do not see the necessity of keeping the patients in bed for such a length of time. I do not know that I have had a case of vaginal hysterectomy in the last five years that has been in bed more than a week or twelve days; I don't believe that the angiotribe could shorten that time. I remove the gauze on the second day; and at the end of five to twelve days the patient is ready to sit up. It seems to me that the angiotribe is a very clumsy instrument. If you look up the literature in the French and German journals, you will find many cases of fatal secondary hemorrhage following the use of the angiotribe. The technique may have been faulty, as many cases die from secondary hemorrhage when the ligature is used improperly. The angiotribe, however, was gotten up as an instrument to prevent secondary hemorrhage and it is said to be safer than the ligature. I do not believe that we can remove as much of the broad ligament with the angiotribe as with scissors and ligature. In operations for cancer, the hemorrhage is best controlled by applying a provisional ligature on the internal iliac. In working up through the broad ligament, ligating first the uterine and then the ovarian artery, that can be done just as well with the ligature as with the angiotribe.

Dr. Wm. H. Humiston, Cleveland, Ohio—I believe the angiotribe is a useful and practical instrument, and will have a wide range of applicability. Any surgeon who has seen Dr. Goffe use this instrument in vaginal hysterectomy will agree with me that he is not delayed by using the angiotribe. It certainly is not a clumsy instrument in his hands. I believe that with the angiotribe vaginal hysterectomy has been so perfected that it has done away with a great many disagreeable symptoms following the use of the clamps; and avoided sloughing and the accompanying foul-smelling discharge. By using the angiotribe the vaginal incisions can be closed with sutures without danger from hemorrhage or sepsis, and the patient can arise from her bed in two weeks with safety. I predict the angiotribe will be more extensively used in the near future.

Dr. W. E. Ashton, Philadelphia, Pa.—I have listened with a great deal of pleasure to the papers read. Personally I have had practically no experience with the angiotribe, for the simple reason, not that I do not believe the instrument a good one for vaginal work, but because the majority of my operations are by the abdominal route, where I would not use the angiotribe, even if it resulted in what has been claimed for it to-day. I believe in doing my hysterectomies by the abdominal route, as we need the support of the broad ligament to support the vaginal wall. Although I have had no personal experience, I believe that in simple pelvic work, for removal of appendages, the angiotribe is a good instrument.

In reference to Dr. Newman's paper I believe that the points he calls attention to are important. Care must be exercised in curetting and also in properly selecting the operation in cases of laceration of the cervix. I have seen a great many operations of curettement done carelessly. I have done them myself. It is a simple operation, providing the proper technique is carefully observed. If not, you not only gain no result from the operation, but you endanger your patient. Therefore, more care should be exercised in these cases of curettement.

With reference to the aseptic precautions and the technique of the operation, one of the principal points is the dilatation of the uterus. The instrument we use for rapid dilatation is a powerful one and it does not take long to dilate the uterus. If this is not realized the uterus in the lower part may be lacerated and you do not get the dilatation in the upper part which you would obtain if the dilatation is slow. Dilate the uterus slowly; take ten or fifteen minutes at least to procure dilatation and you will find that the entire cervical canal is well dilated, enabling you to curette easily and safely. Unless we have a free dilatation of the cervical canal and free mobility of the instrument in the uterus, you take the mucous membrane off in patches, and in infected cases a curettement would under those conditions be absolutely useless.

With reference to the question of laceration of the cervix I believe the great mistake is often made in not performing a dilatation at the right time. In a cervix which has undergone great hypertrophy, or in which there is a diseased condition of the glands, or disease of the mucous membrane, or any multiple laceration, or a cervix in which the laceration has resulted in extensive loss of tissue, a trachelorrhaphy should not be performed, as it will leave the patient in a worse condition than before the operation. Amputation of the cervix should be done, and your patient will recover not only subjectively, but go on to child-bearing. I have seen this not only in my own work, but in that of others.

Dr. G. B. Massey, Philadelphia, Pa.—This is my first lesson with the angiotribe, and I feel that there are many more lessons before me if the surgeons are going to indorse a plumber's kit. I rise especially to take exception to the statement made by Dr. Carstens, who tells us that a prolapse of the ovary in a young girl is absolutely incurable; and that nothing but a removal of the ovary and tubes, and I presume the uterus—although I think he did not say that—is proper. Now, if the ophthalmologist were guided by that theory, where would be the eyesight of the majority of people, as there are very few of us who do not occasionally have some eye trouble of a congestive nature; and yet the eye is not removed. A large number of cases of slightly prolapsed ovary result from chronic constipation, or from lifting a sewing machine, as an exciting cause, during the prevalence of catarrhal congestion. I will say that I have cured at least a half dozen such cases, in my clinic and in my private practice, where the ovary was prolapsed and tender, but not otherwise diseased. I think it is rare to have an ovary become prolapsed unless there is disease of the uterus and usually dysmenorrhea. With that little displacement I believe it wrong to make an opening, put in this plumber's instrument, and crush those nerves and arteries. I should like to have the Doctor say whether his cases were cured or not, and whether the pain disappeared as a result of that operation.

Dr. L. S. McMurtry, Louisville, Ky.—The discussion has taken a very wide range, and I rise to call the attention of the section to one point only. The essayists have given indubitable testimony to the fact that the angiotribe in skilful hands is an efficient agent for controlling hemorrhage in the class of operations under consideration. The trend of the discussion is to imply that the means of controlling hemorrhage in gynecologic operations by established means, particularly the ligature, is unsatisfactory and in need of improvement. We should be careful to make a distinction between a novelty and a necessity. I trust the speakers who have so extolled the angiotribe will, when closing the discussion, give us the comparative data relating to the use of this instrument and the use of the ligature. The principle of the angiotribe is not new. Other instruments have been devised and extolled to close the vessels of the pedicle by crushing. Torsion also had its day, and was claimed to be applicable to vessels as large as the femoral. These methods are undoubtedly capable of controlling hemorrhage by rupturing the coats of the vessels and closing with clot the several vessels. But the question for consideration is: which is the best method? Is crushing by angiotripsy superior to the skilful application of the ligature? Will it avert hemorrhage as securely as the ligature and maintain that security as effectively? I know nothing in surgery more satisfactory than the skillfully selected and applied ligature as a means of hemostasis, and regard it as superior to any method of crushing that can be devised.

Dr. Miles F. Porter, Fort Wayne, Ind.—I should like to have the gentlemen who recommend the angiotribe tell us what a good angiotribe is; how many pounds of pressure ought to be applied, and how long the pressure should be continued. I applied an instrument with 1970 pounds of pressure, recommended to me by a friend of the angiotribe, and the patient died of secondary hemorrhage. I now have another angiotribe, and I will use it when occasion offers. What is a good angiotribe? *I do not mean in mechanism nor in the method of designing its jaws*; but how many pounds of pressure should be used and how long should we keep it up? Do we require more pressure on the upper part of the broad ligament than upon the lower part?

Dr. H. J. Boldt, New York City—I think several of the gentlemen who took part in the discussion this afternoon committed an error by discussing the relative value of an instrument which they had never used. In order to discuss anything we should have some experience witht the matter under consideration. I can give my opinion of the angiotribe in a very few words. Dr. McMurtry presented the whole matter in a nutshell. I used the instrument from the time it was introduced in this country, and I have it now, although I do not use it except on rare occasions for the purpose of demonstration. Not but that it is a good instrument in appropriate cases, because it will control hemorrhage when properly applied, but I feel more secure with the ligature than with the angiotribe. The disadvantage of the instrument is, that it takes more time to operate with it than with the ligature. I believe it to be safe enough, but do not consider that it is in any way superior to the ligature.

Dr. John C. DaCosta, Philadelphia—I do not want to say anything about the angiotribe except that I always want to see what I am doing.

In using ligatures in cancerous tissue I do not think one is doing good service when the tissue is much involved; and much less service with the angiotribe; and as the whole tissue can not be removed you would better leave the patient alone; she will get along much better with a palliative operation than with a radical one.

I feel that there are too many trachelorrhaphies done in cases where amputation ought to be done. When the cervix is very much involved we ought to amputate; get good sound tissue and draw the mucous membrane over it, stitching it to the uterine canal. Dr. Newman spoke of the danger of tearing the fibrous tissue of the uterus at the internal os. In cases of anteflexion that is just what you want to do. Take, for example, a curved piece of timber and when you straighten that timber out, the inner fibers are put in a state of tension, and the outer in a state of compression. When you bend an anteflexed uterus back you first stretch and then tear the fibers at the internal os, and you must do it if you want to straighten the uterus. You tear them; a blood-clot is formed which becomes organized, and when the patient leaves her bed she has a straight uterus. When you speak of a uterus with an acquired anteflexion after labor, and a torn cervix, that is the case where a trachelorrhaphy ought to be done, and after you have done it the uterus will have a normal curve. I have demonstrated again and again in cases of anteflexed uteri with bilateral tear of the cervix that one need not regard the anteflexion. Dissect the cicatricial tissue away properly, then unite the torn lips, and the uterus will be in a good position.

Regarding curetting, I do not believe that there is a safer or, improperly done, a more dangerous operation. Curettement is easy and safe when properly done, but it depends entirely upon the man who does it. A beginner who uses a sharp curette may drive a hole through the uterus; a trained man will not. I impress on the student the importance of having an eye in the fingers holding the curette so that he can see what he is doing just as the blind man does. You must have trained fingers to work properly.

Vaginal hysterectomy is a good thing—if you want to do an operation for vaginal hernia afterward. If you do not, open the abdomen, do an abdominal hysterectomy, and fasten the stump of the broad ligament down; attach it to the mucous membrane.

Dr. J. Henry Carstens, Detroit, Mich., closing the discussion—The gentleman from Louisville was discussing cancer of the uterus, about which I said nothing; I do not need to answer him. My friend from Washington, who has never used the angiotribe, is certainly not in a position to discuss its use. My friend from Philadelphia spoke about plumber's tools; I do not care whether it is a plumber's tool, or a sewer-digger's tool, or some horse doctor's; it is a good deal better than anything I have. If I want to do my patient good I use it, no matter how big it is.

I do not take out any healthy ovaries; I do not take out an ovary because it is a little dislocated, but the gentleman who compared it with the eye—well, if he gets any patient who has an eye dislocated about three inches from where it should be, I should like to see what the doctor would do if he got a sympathetic ophthalmia. Nobody takes out an ovary simply because it is in the cul-de-sac. You try all kinds of things; but if the woman suffers, the ovary undergoes all kinds of changes and becomes adherent, causing pain and trouble, that ovary must come out or you are not doing justice to the patient.

As for putting in gauze, sometimes I do and sometimes I don't. Sometimes I take it out after two days, and sometimes after five days; I try to adapt myself to conditions. I do not remove every uterus or ovary, nor do I use the angiotribe all the time. I said the angiotribe was good for certain cases of vaginal hysterectomy. I do not think it is good for cancer of the uterus, because the tissue you compress with the angiotribe is supposed to become organized again. When you have a cancerous uterus you want to take away every bit of tissue you can, and I use the clamps, removing as much of the broad ligament on both sides as I can. I can get more tissue away with the clamps than with the ligature, and that is why I use the clamp and not the ligature in cancers. I use the angiotribe in selected cases where you formerly used the abdominal route, in cases where the vagina is small and the ovary away down in the posterior cul-de-sac, and where the abdominal section is difficult.

Dr. H. P. Newman, Chicago, closing the discussion—I think Dr. Carstens has covered the ground very well. In reference to the operation on the cervix, it is not the Emmett trachelorrhaphy that I do, but tracheloplasty. I think the distinction is worthy of some notice. Tracheloplasty means a plastic operation on the cervix, the removal of adventitious tissue, followed by surgical reconstruction of the organ. Remove as much inflamed, indurated, or scar tissue as the case necessitates, leaving enough of the outer cervical mucous membrane, for flaps to use in restoring, as nearly as possible, the normal contour of the cervix, with its canal intact. Do not confine yourself to any classical operation, but conform your procedure to the needs of the individual case.

Dr. Wathen thinks that the use of the angiotribe consumes more time than former methods. I have found the opposite to be the case. It saves time, and I would reply to Dr. McMurtry, who wants to know what are the advantages in the use of the angiotribe, that among them are expedition, complete hemostasis, and the doing away with sutures, and the damage of leaving foreign bodies in the wound or cavity.

The angiotribe does away with that massing of tissue in the broad ligament stump, which too often allows the imperfectly constricted blood-vessels to retract from the grasp of the ligature and bleed into the connective tissue, forming a hematoma. Some eighty odd cases of this accident, following amputation of the ovaries and tubes, have been recorded by Tait alone.

In strong contrast is the linear stump after application of the angiotribe. In this narrow, ribbon-like affair, not thicker than an ordinary blotter, the blood-vessels have been so effectually secured and compressed that retraction is impossible. With the linear stump there is none of that drawing or tension on neighboring structures, giving rise frequently to displacements, disturbed function, tenderness and pain. It is also claimed that there is no sloughing of tissue as in ligation *en masse*, and consequently no granulating surfaces, adhesions, nor scar tissue.

MYOMECTOMY PER VAGINAM.*

J. RIDDLE GOFFE, M.D.

Professor of Gynecology in the New York Polyclinic; Visiting Gynecologist to the New York City Hospital.

NEW YORK CITY.

There are probably no two subjects that so enlist the attention of gynecologists at the present time as those that are suggested in the title of my paper. The first is the value of myomectomy as contrasted with hysterectomy in the treatment of fibroid tumors of the uterus, and the second is the superiority of the vaginal method of approach over the abdominal route in the surgical treatment of pelvic disease in women. Regarding the first, there are staunch advocates of myomectomy as the operation of choice, as the dominant operation in the treatment of fibroid tumors of the uterus; and, on the other hand, there are strong advocates of the sweeping and uncompromising dictum, that in all cases of fibroid tumors of the uterus nothing short of hysterectomy should be entertained. For myself, I believe in conservatism in gynecologic surgery. If part of an ovary can be saved and menstrual function preserved to a woman throughout her natural menstrual period, s [illegible] ari sue. It is my custom to leave one healthy ovary, or a part of an ovary in cases of pan-hysterectomy for fibroid tumor. If, in addition to preserving the menstrual function by retaining ovarian tissue, there is prospect of conception, gestation, and motherhood, my rule is save at least a portion of one tube and preserve for it a patulous canal.

---

*Presented to the Section on [illegible] Women, at the Fifty-first Annual Meetin [illegible] Association, held at Atlantic City, N. J [illegible]

Extending this principle to the uterus—a uterus affected with a fibroma or a number of fibromata—the following rule holds: Remove the diseased portions—as many fibroid foci as can be discovered—but save the uterus. The field for discussion here is very broad, involving the questions as to whether fibroid disease of the uterus is purely a local disease and confined to the uterus or whether, as is maintained by some, it is a general disease and invariably attended by fibroid or cystic degeneration of the ovary and Fallopian tube; whether the symptoms ascribed to this disease are caused solely by the uterine neoplasms or whether many if not most of them are due to accompanying or complicating diseases; whether all foci of the disease can be with reasonable certainty eradicated or whether some must necessarily be overlooked and so continue the symptoms, and later necessitate a second operation.

The object of my paper, however, is not to discuss this feature of the title, but, granting that myomectomy has been determined upon in any individual case, to present for your consideration the superiority of the vaginal method of approach over the abdominal route.

Two years ago, at the Denver meeting, I presented before this Section a paper advocating the treatment of retroverted uteri—with or without adhesions, and with or without complications involving diseased appendages—by shortening the round ligaments through the anterior vaginal incision. In this paper I reported 31 cases, illustrating all forms of complications in retroversion of the uterus; and had the pleasure of demonstrating to many of you the procedure itself, on a patient at the Arapahoe county hospital. Last year at the Columbus meeting I insisted upon the wide application of the vaginal method of attack to all pathologic conditions in the female pelvis, including hysterectomy for fibroid tumors. The object of my paper now is to speak specifically of its service in the operation of myomectomy. Probably this can not be done more forcibly than by presenting to you the clinical picture of a few cases:

Case 1.—Mrs. S., aged 37, a large-framed, straight, well-built Irish woman, the wife of a policeman, presented herself with the following history: Married ten years, one miscarriage several years ago; no children; painful menstruation twice each month, lasting six or seven days; constant backache; nervous; irritable and anemic. Upon examination the uterus was found retroverted, bound down by adhesions; and in the posterior wall was a fibroid tumor the size of a hen's egg. The vaginal operation was advised, with the understanding that the full preservation of all the organs possible should be carried out, although the patient insisted that she did not care what was done, provided it secured the restoration of her health. Operation was performed at the Polyclinic, October, 1899. After curetting the uterus and packing it with iodoform gauze, the posterior incision was made, opening into Douglas' cul-de-sac. Through this opening adhesions were carefully broken up by digital manipulation, as far as could be reached; but the tumor could not be made to present through this opening with sufficient clearness and facility of approach to justify its removal. The anterior incision was therefore made, and the bladder dissected from the uterus. The anterior vaginal wall was also split throughout its entire length by a longitudinal incision and the bladder dissected from the vagina to the extent of an inch on either side. Through this opening the balance of the adhesions were broken up, and by patient manipulation, the uterus was delivered into the vagina. With the fundus at the vulva and in full view of the class of students, the tumor was shelled out in the usual way and its bed closed by tier sutures of chromicized catgut. The round ligaments were then shortened through the same incision, according to the method described in my previous paper, the uterus restored to the pelvic cavity, the bladder adjusted to its normal position, and the longitudinal incision in the vagina closed by a running catgut suture. A strip of iodoform gauze was passed into Douglas' cul-de-sac for drainage; the vagina lightly packed with the same gauze, and a self-retaining catheter inserted. The patient has since been free from all the symptoms of which she formerly complained; is experiencing normal and regular menstruation, and considers herself in perfect health.

Case 2.—Mrs. B., of Elmira, N. Y., presented herself at my office December 1, 1899, and gave the following history: Aged 43; married twenty years; the mother of four children, the youngest being 8 years of age. She complained of having endured wretched health since the birth of her last child, her condition growing steadily worse. She was anemic, thin, nervous, and complained of insomnia. Her menstrual flow was excessive, and she suffered from a constant backache and leucorrhea. Upon examination it was discovered that there was a greatly relaxed *introitus vaginae,* a bilateral laceration of the cervix, with diseased glands and hypertrophied tissue. The uterus was retroverted and immovable, being wedged in place by a number of fibroid developments on the posterior wall and at either side. Three days later, at my sanitarium, she submitted to operation. The uterus was curetted and packed with gauze, trachelorrhaphy was performed, the anterior lip being completely rimmed out. The T-shaped incision was then made in the vagina anterior to the cervix, the bladder stripped from the uterus, and by patient, careful and persistent manipulation, the uterus, with its fibroids, was delivered into the vagina. Two of the growths, each somewhat larger than a normal ovary, were found to be subperitoneal and partially pedunculated. These were readily pinched off and smaller neoplasms, to the number of five, making seven tumors in all, were dissected out of the uterine wall, the incisions being so made as to facilitate the shelling out of two tumors through the same incision in each of two instances. There were no adhesions in this case. The round ligaments were then shortened through the anterior incision and the operation completed as in the former case. The patient's temperature remained normal throughout her convalescence and on the nineteenth day after the operation she left the sanitarium for her home. She has continued to regain her strength and general health, has been relieved of all her symptoms, and has recently written me a cheerful letter of thanks for her restoration to health.

Case 3.—Miss M., of Yonkers, N. Y., was seen by me in consultation May, 1900. She gave the history of having been a sufferer all her life from dysmenorrhea, backache, and uncomfortable dragging sensations in the pelvis. Examination revealed a large retroverted, adherent uterus, with a small fibroid in the anterior wall just above the neck and between the uterus and bladder. Vaginal operation was advised, with the idea of removing the fibroid, freeing the uterus from its adhesions, and shortening the round ligaments to cure the retroversion. The attending surgeon, who is a surgeon of note, was desirous of doing the operation himself under my superversion. The operation was performed as described in the two previous cases, but the tumor was removed previous to delivering the fundus into the vagina, by lifting up the bladder on a strong retractor and dragging down the uterus with vulsellum forceps. The tumor was brought into full view and two smaller tumors were revealed, one at the side and the other a little higher on the anterior wall. The three neoplasms were removed in the usual way, the fundus was delivered into the vagina, and the round ligaments were shortened. The other steps in the completion of the operation were carried out as usual. There were no untoward symptoms in the patient's convalescence, and I am informed that she made a most satisfactory recovery.

It will be noticed that these cases followed the general rule that uteri presenting small fibroid tumors are usually found retroverted; there are exceptions, but I think the rule will hold. In this fact lies a suggestion bearing upon the origin of these neoplasms, viz., the interference of circulation and consequent nutrition subsequent to the displacement. The question at once arises: which is the cause and which the effect? Do the tumors produce the displacement or does the displacement afford occasion for the development of the tumors? I believe the latter is the case and that we must look to the interference in the circulation and the subsequent nutrition as the occasion for the development of these growths. Competent pathologists are of the opinion that these growths arise from a proliferation of the muscularis of the arterioles. This would indicate that their origin lies very close to interference with the circulation as a cause. The facility afforded by the vaginal method of approach for the cure of the retroversion is an additional factor in favor of it; for even if, as some claim, the presence of several small growths implies a multiplicity of foci, their development may be retarded by a restoration of normal circulation and metabolism by restoring the uterus to its normal position.

The superiority of the vaginal method over the abdominal in meeting this condition is the same as that which attaches to all vaginal work; the dangers are less, incomparably less; the convalescence is smoother and simpler, the patient being relieved of the annoyance of stitches, adhesive plaster, bandages and dressings; there is no visible scar to constantly remind her of her experiences, and above all there is no danger of hernia. The question arises: what shall be the upper limit to the size of fibroids that can be dealt with in this way? Experience and facility of operation on the part of the operator can alone determine this question, although the location of the tumor plays a large part in its solution. The traumatism, so far as the patient is concerned, is of so slight a character, that even if the effort in this direction must be abandoned and the abdominal incision made, very little detriment attaches to it, except the loss of time. After the incisions are made, opportunity is afforded to decide whether a myomectomy or a hysterectomy is indicated; if the latter, all the steps already taken are essential to the procedure and no time is lost.

During the past three months I have dealt with two private cases in this way, deciding upon vaginal hysterectomy after the tumors had been carefully located and the impracticability of myomectomy ascertained. In both these cases the tumors weighed something over two pounds, and occupied so much of the fundus that it seemed impossible to enucleate them or morcellate them without destroying the openings of the Fallopian tubes. The desirability of retaining a reconstructed uterus of that character was not apparent and a hysterectomy was done in each case.

MYOFIBROMA UTERI.*

HERMANN J. BOLDT, M. D.

NEW YORK CITY.

The greater number of solid neoplasms of the uterus are fibromyomata; tumors, consisting of fibrous connective tissue only—fibroids—or of muscle only—myoma—are comparatively rare. It is the preponderance of one or the other of these tissues in a tumor on which the consistency depends, and to some extent the rapidity or slowness of its growth.

The original seat of such neoplasms is, strictly speaking, interstitial; that is, the growth takes its starting-point in the parenchyma of the uterus, and subsequently grows in the direction of least resistance; thus subserous and submucous fibromyomata are formed. Real subserous tumors are freely movable, unless they become incarcerated in the true pelvis. They rarely cause symptoms, except when they attain a large size, or become incarcerated or twisted.

Interstitial tumors are of two varieties: 1, the greatest number are encapsulated and may, therefore, be readily enucleated, if the capsule be incised; 2, those which are diffuse—adenomyomata—and blended with the uterine wall. There are instances of interstitial fibromyomata situated in the corpus, which produce torsion at the junction of the uterine body with the cervix, and an instance has been reported in which complete separation from the cervix took place.

Under the term of submucous fibromyomata only those should be classed which have been born or extruded almost completely into the uterine cavity. Those still remaining mostly within the uterine wall should be classed as mixed tumors—a combination of submucous and interstitial situations.

The histogenesis of fibromyomata is still a disputed point. My own studies would lead me to believe, with Rösger, that they arise from the muscularis of the capillaries. This, too, would explain why in the earliest stages, we never find mixed tumors; from a histologic standpoint they are invariably pure myomata; fibrous connective tissue is absent until the tumors have assumed a greater size—for instance, a diameter of .25 cm. Yet the careful researches of Virchow and Cordes must be given due consideration. According to these observers, they are due to swelling and proliferation of the uterine muscularis.

A variety of desmoid tumor which has given rise to much controversy is that containing glandular elements—the adenomyomata. It was von Recklinghausen[1] who shed true light on the origin of the epithelial elements contained in these growths. He ascribes their origin to the endometrium, or the Wolffian body. When the epithelial bands are derived from the endometrium they resemble in construction those found in the uterine cavity, and the tumor is located centrally to the uterine wall. If the exit of the glandular formation toward the uterine cavity becomes obliterated, cystic dilatation of the gland cavity is apt to result. From this variety of adenomyomata we can readily conceive the coexistence of carcinoma, and hence his researches are a valuable contribution to the etiology of uterine cancer. The greater number of adenomyomata, however, have their origin in the Wolffian body. The clinical peculiarity rests on their fusion with the parenchyma of the uterine wall. T. S. Cullen[2] describes three instances of these tumors, and from his examinations corroborates the conclusion of v. Recklinghausen. Ludwig Pick,[3] in a very instructive research, shows that some of the neoplasms found and considered under the head of adenomyomata have their origin from the Müllerian ducts.

*Presented to the Section on Obstetrics and Diseases of Women, at the Fifty-first Annual Meeting of the A[illegible] Medical Association, held at Atlantic City, N. [illegible] 5-8,

[1] Centralblatt f. Gyn., vol. xx,

If a fibromyomatous uterus is examined, we find that its endometrium usually is thickened, except in rare instances of large interstitial tumors, when the opposite condition may exist, as the result of tension or stretching of the tumor on the endometrium. This change, of course, does not take place in pedunculated subserous neoplasms. The muscular wall of the uterus undergoes hyperplastic changes, the connective tissue and muscular cells being increased as the result of an irritative process. We likewise find various pathologic changes in the tubes and ovaries of fibromyomatous uteri. In the tubes the most frequent change is an endosalpingitis, but we also frequently see interstitial salpingitis, hydrosalpinx and pyosalpinx. Fabricius[4] makes known the findings in two cases which are worthy of careful consideration. The ovaries have usually been found to be enlarged, due to an increase of the interstitial tissue, and in the size and number of the follicles. In a number of ovaries studied by the writer the vessels had undergone hyaline degeneration, and their lumina quite frequently were found to be constricted.

Various changes may take place in a fibromyoma. I recall two instances of large tumors which disappeared entirely without any treatment, before the menopause. Both women had complained of the weight caused by the size of the growths. When seen two or three years later respectively, no trace of the tumor was found upon examination. Another instance of a large tumor complicating pregnancy disappeared entirely within a year after parturition. A still more curious phenomenon was recently observed by the writer. A woman pregnant in the fourth month, who had a myofibroma which filled the true pelvis and which could not be dislodged at the time, was directed to go to term and then have extirpation performed. She had an uneventful delivery, with seemingly complete disappearance of the tumor previous to the termination of gestation.

Such atrophic changes are presumably due to changes in nutrition, inexplicable, however, in the last case cited. Calcareous degeneration, which may also be looked upon as a form of atrophy, is another favorable change which may occur. It is rare, but one instance of such complete transformation has been observed by the writer, accidentally discovered on autopsy.

Sarcomatous degeneration must be classed among the most serious changes which such neoplasms may undergo. The myofibromatous structure is transformed into sarcoma cells and then the growth is apt to progress quite rapidly. The sarcomatous change becomes diffuse by infecting the adjacent structure similarly. The malignant areas have this peculiarity, however: they frequently perish early by necrobiosis so that one is not apt to find a large uterine tumor degenerated into a single sarcomatous mass.

According to Menge, in a discussion before the Obstetrical Society of Leipzig, Feb. 18, 1895, there is much danger of the walls of the lymphatics, in lymphangiectatic myomata, undergoing sarcomatous changes, and such tumors readily become myosarcomata. He presented two specimens to substantiate his belief. In the continued discussion, M. Sänger expresses the belief that seeming fibromyomata which take on a rapid growth after the climacterium are probably all sarcomata. The presence in them of giant cells and myoblasts is positive proof of this. The long retention of the spindle shape of the cells in such changed tumors goes to show their origin from the former benign cell.

The change into carcinoma has been alluded to, and in some cases is based upon the proof adduced by v. Recklinghausen, which has previously been considered. In another way, carcinomatous changes in a myofibroma may take place from polypi, the mucosa of which has become carcinomatous, the malignant changes then invading the deeper structures of the myofibroma.

It would be of great value were it possible to diagnose the beginning of sarcomatous degeneration in a fibromyomatous tumor; unfortunately this can not be done; it may, however, be suspected, if a tumor which has been stationary for a long period without causing decided inconvenience to a patient suddenly begins to give rise to complex symptoms which can not be explained from the size or situation of the tumor. When such growth, therefore, begins to cause pains, a feeling of malaise, etc., associated, perhaps, with an increase in size, we should consider it a practical hint and strongly advise its removal, because of the probability that degenerative changes of a malignant character are in progress. A change in the symptomatic condition of such a patient should always be noted with suspicion, not only on account of possible degenerative changes, but also on account of other serious changes which may take place in the neoplasm, such as inflammation, gangrene and suppuration, myxomatous and cystic degeneration, in any of which conditions, delay in operation is serious. There is, however, a physiologic condition, in which the sudden appearance of such symptoms as have been alluded to are apt to take place; I refer to pregnancy. The physician must be on the alert for such complications and endeavor not to commit an error in the diagnosis.

Taking for granted that the diagnosis of a fibromyomatous tumor of the uterus has been made, the question of treatment naturally arises. One must come to the conclusion, if a close observer, that the pendulum has made a swing toward quick and radical treatment. In fact, this tendency has gone even further with many, during the past few years, than the prognosis of the condition warrants. It is true that fibromyomata are not so benign as they were once thought to be, but it is also true that they are not as dangerous as some would have us believe in their writings and discussions. Many such tumors have been observed by the writer, for a goodly number of years, without a justifiable indication for operation, having in his opinion, become manifest. Others again were observed, in which an indication was considered present—mainly severe menorrhagia and metrorrhagia, yet the patients declined operation, and they seemingly got along fairly well on palliative treatment; in fact, with but few exceptions, the symptoms decidedly improved, and in some the size of the tumors diminished.

The reason for such radical change in treatment may be found in the greatly improved prognosis which operation gives. Abdominal hysterectomy, in the hands of one who is a master of the technique, should not give a greater mortality than simple ovariotomy. At least, such has been my experience during the past few years, with by no means a moderate number, and these not all simple cases. Yet the unexpected sometimes happens, and, therefore, we should not indiscriminately advise radical operation for fibromyomata, not only for fear of the mortality—this being a minor consideration in view of the direct results obtained by an accomplished operator—but on account of the subsequent changes produced in a woman deprived of her pelvic organs during the period of active physiologic activity.

---

[2] Johns Hopkins Hospital Reports, 1896.

[3] Archiv f. Gynæk. vol. lx, p. 176, etc., ueber die epithel. Keime der Adenomyome.

[4] Ueber Cysten und der Tube, am Uterus und dessen Umgebung. Archiv f. Gyn. vol. l, p. 383-402.

If by any measure adopted, we can produce a symptomatic cure, it should be done in preference to a radical operation. It must not be forgotten, however, that there are instances, although comparatively rare, in which nothing but undelayed operation should be advised; they have been mentioned among the degenerations of serious character.

The social position which a patient occupies must be considered first and foremost. This is obvious, because a woman of the laboring class can not observe the rules which are laid down for those in better circumstances, in regard to rest, diet and hygiene. Internal medication is variable. No specific has been discovered to check the size of the growth, or diminish it; to stop profuse bleeding or the pain sometimes associated with the neoplasm.

I have watched a number of patients who were placed on thyroid extract and mammary extract, the latter so strongly recommended by Shober and Polk in this country, and by Bell in England. I have seen three instances of undoubted improvement in every respect, even a slight diminution of the tumor. All of the patients alluded to have used the remedy one year or longer, but so far as the size of the tumor is concerned, it is doubtful if any permanent diminution has taken place; we know that the tumors change in size with the menstrual period, and also that the amount of adipose tissue in the abdominal walls, during the use of these remedies, diminishes in many instances, so that the medicaments are at best rather uncertain; absolute measurements are impossible in any case.

Among remedies for local use which I consider palliative, electricity has held a prominent position. I say held, because the enthusiasm with which it was accepted has died out, and among its former strong advocates equally firm condemnation is heard. Its indiscriminate use is justly condemned. When first introduced according to the technique devised and advised by Apostoli, nearly every woman who had a fibromyoma, or was thought to have one, was subjected to a course of galvanism, and hence the remedy, which was intended to be of benefit, did more harm than good. The matter stands thus, in my opinion: There is a limited field for its use, but only for palliative treatment. Not a single instance of disappearance of the growth has been observed, but some tumors have seemingly diminished in size. This treatment is indicated only in interstitial growths of moderate size, up to or below the umbilicus, when there is no other serious lesion in the pelvis—as pyosalpinx, for instance—and when the patient can bear it without causing subsequent distress, such as increased pelvic pain or neurasthenia.

From this it is apparent how exceedingly small the field is when the use of electricity may be expected to prove beneficial to the patient. In the class of cases just mentioned as suited for electrical treatment, the bleeding, though previously profuse, becomes lessened and the pain associated therewith diminished greatly; in some instances it entirely disappears, so that in this class, but only in such cases, symptomatic cure can frequently be established. Treatment should not be continued if evidence of pelvic inflammation follows its use, or if subsequent to or during the treatment much pain is experienced in application of a moderately strong current—50 to 100 milliamperes.

The use of the curette has been abandoned almost entirely by the writer for the purpose of stopping the bleeding due to the accompanying hyperplasia of the endometrium. Two instances of tumors causing profuse menorrhagia and metrorrhagia in women, aged 42 and 45 years respectively, who declined long treatment as well as a radical operation, were cured of their bleeding by the use of the galvanocautery. The cervix was thoroughly dilated, and the dome-shaped electrode of Byrne was rapidly carried through the canal. The interior was thoroughly charred, as in malignant disease, but the process was not carried to such depth. It is now six and eight months, respectively, since this was done, and both patients report themselves cured.

Various other forms of local treatment to stop the bleeding have been used with variable success; as local applications of ferripyrine; liq. ferri sesquichlorati; zinc chlorid and iodin.

Some years ago, I was, with others, favorably impressed with an operative palliative treatment, consisting in ligation of the uterine arteries. Unfortunately, the continued observation of the patients thus treated showed that the method did not bear the test of time; it has, therefore, been abandoned.

ARRHYTHMIA CORDIS COMPLICATING FIBROMATA UTERI.*

J. WESLEY BOVÉE, M.D.
Clinical Professor of Gynecology, Columbian University; Fellow American Gynecological Society, Etc.
WASHINGTON, D.C.

The study of the life history of uterine fibromata, with their multiplicity of combinations, has been patient, persevering and full of vexations. At first, considered perfectly benign, we have come to recognize the probability of their producing great harm and even of taking on malignant degeneration.

Their complications are becoming constantly more numerous. Sorel[1] has found they have a close relation to glycosuria. He demonstrated this relation in some marked cases of glycosuria, extending over a period of years, complicated by uterine fibroids, and in which a quick and decisive cure of the pathologic discharge of sugar followed hysterectomy.

What etiological relation, if any, exists between arteriosclerosis and uterine fibroids is still a matter of conjecture. La Force[2] considers it a potent cause of fibroids of this organ, and many believe a condition of arteriosclerosis is usually present in most cases of these growths. It would seem but rational to find such condition present, but thus far I am not aware of its positive demonstration in any instance, except in advanced life. Certain conditions of the nervous system in the formative stage of fibroids have been noticed. Insomnia, headache and hyperesthesia of the sensory organs are present in a marked degree, according to Grace P. Murray.[3] Many nervous symptoms during the presence of these fibroids have been observed. One striking case was that of loss of vision, which returned immediately after hysterectomy. As the female generative organs are very closely allied with the nervous system, troublesome and, perhaps, grave nervous symptoms may be expected in cases of uterine fibroids. Although organic cardiac disease is often associated with these tumors, cardiac symptoms in the absence of any lesion of that organ very rarely exist in such cases. In an experience with fully one thousand fibroids of the uterus I have seen but one such case. In a careful search of the literature in the library of the Surgeon-General's office, in my city, I fail to find any case reported, or any reference to the subject. It is this great rarity that has emboldened me to report my own observation of the condition, hoping to interest the profession in further study of this complication of fibroids of the uterus. The history of the case is as follows:

---

*Presented to the Section on Obstetrics and Diseases of Women, at the Fifty-first Annual Meeting of the American Medical Association, held at Atlantic City, N. J., June 5-8, 1900.

Kate R., 26 years of age, colored, was admitted to Columbia Hospital for Women, Oct. 23, 1896, complaining of "a pain in the stomach" and a tumor in the abdomen, first noticed three years before. She was never married, but had had two abortions, the last of which occurred three years before as the result of a fall. Her menses began at the age of 17 years, usually lasted seven days, were regular, profuse and quite painful, and last occurred Oct. 1. Her appetite was fair and her bowels regular; she complained of unusual fatigue on ascending stairs. She was well nourished, had no glandular enlargement and no edema, but the mucous membranes had an increased brightness of color. The area of cardiac dulness was very slightly increased. No cardiac murmurs were found. There were irregular distinct pauses in the heart sounds, with corresponding radial pulse intermissions. These varied from every third to every twentieth beat, and were always synchronous. No other irregularity of the heart action was observed, and the pulse was from 62 to 74. In the abdomen and pelvis were found freely movable, multiple uterine fibroids, filling the pelvis and extending to two inches above the umbilicus. Absolutely no abnormality other than the presence of the tumors and the cardiac arrhythmia was found. She was kept in bed, fed on highly nutritious food and given strychnia in liberal doses. Frequently consultations with other members of the hospital staff were held, the verdict, always unanimous, was every time against the advisability of proceeding with the operation until her cardiac symptoms were removed. She begged to be allowed to get out of bed, but this favor was strenuously denied. December 1 she was unimproved and had no complaint but remaining in bed and waiting so long for the operation. About this time Col. W. H. Forwood, U.S.A., was visiting my wards, and I requested him to examine the patient, which he did, and expressed the opinion she would pass successfully through the operation, and further that stimulation would entirely remove the arrhythmia. Acting upon his suggestion, abdominal hysterectomy was done Dec. 17, 1896, under ether anesthesia. It was noticed her pulse immediately improved when the ether was started and improved to the third stage of anesthesia, when it was perfectly regular. During the operatin, the anesthetizer found no skipping of beats, and the pulse was 78 when she left the table. When she reached her bed he again noticed the arrhythmic action of the heart, which gradually grew more marked, and at the end of a day was practically the same as before the operation. From the time of the operation till January 27, the date of her discharge from the hospital, her pulse varied from 62 to 104, reaching the latter number but once. During this period the arrhythmia remained practically the same as it was when discovered. She had never been told she had heart trouble, nor did she suspect it. Fortunately she was not worried by the frequent examinations of heart and pulse.

Arrhythmia of the heart is defined as being a deviation of the normal rhythm of that organ; several varieties of it have been observed: 1, the true intermittent, in which the ventricular contractions are uniform in degree, but at regular or irregular intervals, a pause, covering the time of one or more contractions, occurs; 2, the false intermittent, which differs from the true variety in that the contractions at intervals are not entirely suspended, but are so feeble that no arterial pulsation is discoverable; 3, a variety, the chief symptom of which is the *pulsus bigeminus*. In this variety a full systole is followed by a short systole, then coming a short and incomplete systole, and then a long systole; 4, a variety in which a regular irregularity of the force of the systole is noted, producing an alternating weak and strong pulse, known as the *pulsus alterans;* 5, delirium cordis, in which the irregularity of systolic contraction is irregular and the pulse-rate very fast. These are the principal forms of cardiac arrhythmia, though others are observed. In some cases combinations of these varieties are noted, and at times different combinations have been noticed in the same individual. It is not necessary to mention in detail the nerve-supply of the heart, as all of you are familiar with it. Besides, after removal of the heart from the body, its rhythm has been continued for a considerable time, as noted by various observers, demonstrating its independence of the central nervous system. And yet when we study the etiology of cardiac arrhythmia, we must acknowledge the influence the central nervous system exerts over it. Wenkback, in a paper entitled "The Physiological Explanation of the Arrhythmic Action of the Heart," read before the eighteenth German Congress for Internal Medicine, says: "Modern physiology teaches the normal heart action depends on: 1, the automatic excitation of the heart-muscle; 2, the power to conduct the motor impulse from muscle-cell to muscle-cell; 3, the contractile power of the heart-muscle. An increased automatic excitation is the cause of *pulsus trigeminus intermittens* and similar pulse forms. Lessened power of transmission explains Stokes-Adams' phenomenon and some forms of bradycardia; an increased power of transmission causes delirium cordis; lessened contractile power causes *pulsus alterans.*" According to Roy and Adami[4], simple intermittency may be due to weakened auricular impulses, ventricular contraction not following regularly. Huchard[5] suggests the special susceptibility of different points in the heart-muscle, which act like the broken cell of the galvanic battery in the conduction of the impulses. B. W. Richardson[6] says, "Intermittent pulse is purely of nervous origin and is always induced—when not inherited—by shocks upon the sympathetic or vital nervous system—such as grief, fear, rage, worry, and vital exhaustion." He also says it may be coincident with heart disease. In infancy it indicates nervous derangement, while in young adults it has the same meaning and tells the story of beginning failure of power. Occurring suddenly after any great event which has told upon the mind, it may be a sign of serious import. Richardson found it the first evidence of physical derangement, in five cases of disorder of the mind in which suicide was attempted, and believes that in advanced life and premature age it heralds nervous failure. He further says, "With this condition chronic they pass through all acute diseases less favorably, and sink more readily from surgical operations. In children it may pass away with growth and increase of strength. In adults, when estabished, it never goes away entirely though it may be absent for long periods when the health is excellent." Huchard[7] says we may physiologically recognize three classes of arrhythmia: those of nervous, mechanical and myocardial origin, while, from a pathologic standpoint there are six, as follow:

1. Nervous and cerebral. Meningitis—simple and tuberculous, apoplectic stroke; hemorrhage—cerebral or meningeal; cerebral tumors; compression of the vagus by tumors.

2. Neurotic and psychic. Hysteria, neurasthenia, epilepsy, exophthalmic goiter and emotions—paroxysmal arrhythmia.

3. Reflex. Diseases of the intestine; uterus; stomach, etc.; arrhythmia from cold.

4. Toxic. Digitalis, tea, coffee, tobacco, abuse of alcohol, etc.

5. Critical arrhythmia of acute diseases. Convalescence of typhoid fever; at the moment of defervescence of pneumonia and other acute diseases.

6. Arrhythmias of cardiopathies. *a.* Valvular. Insufficiency of the mitral valve; stenosis of the mitral valve. *b.* Myocardial. 1, acute myocarditis in typhoid, grip, variola, etc.; 2, chronic myocarditis—senile arrhythmia, degeneration and overcharge of the heart; 3, arterial cardiopathies; 4, endocarditis, pericarditis, adhesions of the pericardium; 5, insufficiency and stenosis of the aortic valves, of arterial origin; 6, sometimes angina with concomitant cardiosclerosis.

Lauder Brunton, in his article on "Intermittent Pulse[8]," mentions the case of a woman dying suddenly at 84 years of age, having had arrhythmia 67 years. Richardson describes a case in which death from senile decay occurred and in which the pulse never failed to intermit less often than once in eight beats. When she was quite insensible, the pulse, with long hesitations, came up again and was beating at the end, even when respiration had ceased. Subsequent examination showed the heart to be the healthiest of all her organs, the coronary arteries normal and the muscular structures quite free from fatty and granular degeneration. Tirard[9] found in twenty applicants for life insurance, who had this symptom, ten had heart-disease, five dyspepsia—one of these had heart disease and two malaria in addition—three albuminuria—one of whom had liver disease, one lung disease—and three had used tobacco to excess.

By considering the causes of arrhythmia we may readily understand it may be an indication of a very grave malady or of little moment. It therefore becomes necessary to endeavor to ascertain its cause, which will not always be an easy task. Under any circumstance it is a symptom that commands the boldest surgeon to pause. If no serious malady be found to account for it, surgical operations may be proceeded with, though with great care, as the condition of the heart must be considered as a handicap. In my case, I was not able to trace cause and effect, and proceeded with hysterectomy only after observing the patient two months and finding no severe pathologic condition to account for the arrhythmia. That it was not reflex from the tumor, as was for some time conjectured, is clearly proved by its resumption and continuance after hysterectomy. It disappeared only during paralysis of the voluntary muscles and unconsciousness, though present during sleep. This is evidence of its nervous origin.

In conclusion I would suggest: 1, arrhythmia cordis is not yet well understood; 2, as a complication of fibromata uteri it is exceedingly rare; 3, it has a serious import, the degree of which depends upon the condition causing it; 4, its presence as a complication of conditions requiring surgical operations necessitates a careful inquiry into its cause before the operation is performed; 5, it is a contraindication of more or less influence in all cases requiring surgical operation; 6, if not due to a severe pathologic lesion other than that for which the operation is to be performed, its presence does not necessarily prohibit operation, but lends additional jeopardy to the patient's recovery.

DISCUSSION ON PAPERS OF DRS. GOFFE, BOLDT AND BOVÉE.

Dr. W. Evelyn Porter, New York City—The subject is one of great interest and one which I feel has not been given sufficient attention by the profession at large. The tendency in the past few years has been to do vaginal hysterectomy indiscriminately in all cases of small fibroid tumors; there have been comparatively few reports of any considerable number of cases of myomectomy. Many of the larger tumors can be easily removed by myomectomy, although the field for the operation is much more limited in this class of cases. I have personally performed the operation a number of times with extremely satisfactory results. I adhere strictly to the limit as regards the age of the patient. I believe that the operation is one which should be done with due consideration to the possibility of malignant development. In a patient beyond the age of 40, it should be limited, as there is always a possibility of the development of a malignant growth, as Dr. Boldt has told us. The technique of the operation is very simple. The location of the tumor must help to decide whether we make an anterior or posterior incision. In cases where there are adhesions in small tumors, it is very simple, but I prefer doing an Alexander's operation rather than the anterior fixation sugested by Dr. Goffe for coexisting displacement. The detail of the operation is perfectly simple, making a linear or crucial incision and enucleating the fibroid tumor. One rarely has any hemorrhage, and there are very few arguments against the operation, except the possibility of the development of a malignant growth. Where we find any difficulty in removing the growth from below, the abdominal operation is certainly advisable and to be advocated. The results have been excellent, and some of the women have been delivered of healthy children subsequent to the abdominal myomectomy for large tumors. I advocate the operation in young women.

Dr. Frederick Holme Wiggin, New York City—In support of the statement made by Dr. Goffe about making the incision along the anterior vaginal wall in many of the operations about the uterus through the vagina, I wish to say that it certainly facilitates the work in removing fibroids. There are one or two points which Dr. Goffe has not brought out. Where the tumor is larger than usual the dissection should be carried pretty far laterally, as with a small incision you have much trouble in getting down the fundus and much time is lost. I have had a number of cases of large fibroids which I have removed by myomectomy, where, if I had relied on abdominal hysterectomy, the patient would not have survived. The operation was undertaken largely because the patient was suffering so much that life was not worth living. I stated the facts of the case and the danger to the patient and her husband, and they decided to take the risks. I opened the abdomen by means of a large incision in order to get at the tumor quickly; by making an incision through the uterine tissue there was no difficulty in shelling out the tumor. The uterus contracted very rapidly and there was very little hemorrhage, the patient making a splendid recovery. I do not think that this subject has been discussed sufficiently. I have been very much surprised at the ease with which these large tumors can be removed in this way.

Dr. J. Henry Carstens, Detroit, Mich.—Myomectomy is certainly excellent, and in certain selected cases, it is admirable, but there are many cases where it can not be done. One point has not been brought out, and that is that there are fibroids that are not encapsulated. Some fibroids have no beginning nor any end. They are real adenomyomas and go all through the uterine tissue; you can not shell them out; you must take out the whole uterus, but you can not tell this beforehand. The malignant changes are of importance. I make the age a rule; the older the patient the more I am inclined to do a vaginal hysterectomy, and the younger the patient the more I am inclined to do the abdominal operation and myomectomy, that is, preserve the uterus.

Dr. Joseph Price, Philadelphia—Nothing could be of more vital importance than a uniform consensus of opinion. We are not talking to a class of specialists in this gathering, and for us to change our bonnets (methods) four times a year as the women do, without clearly stating our reasons is an error. We know very well that we have simple pedunculated forms of fibroids which are controlled easily by a small ligature or forceps; and if they occupy the pelvic basin in pregnant women the delivery is a perfectly safe procedure, but men who do hysterectomy will admit, after removing a good number of them, that it is always an imperfect and unsafe procedure. Dr. Goffe tells us he removed seven, but he does not know that more did not exist, as we all know that there may be many small myomas scattered throughout the uterus.

Regarding the nervous disturbances referred to by one of the authors, I scarcely believe that a woman carrying a fibroid is ever right mentally. I never operate on a woman for fibroid but what I make her and her husband and family admit that she was in better mental condition after the tumor was removed. I know that removing the uterus with a fibroid makes them much healthier physically and mentally than before the operation. As to procedure, but few at present prefer the lower route; if tumors are small and uncomplicated the operation is easy and the patients do very well, but it is not an operation they can use in every case, as the abdominal. The procedure is very much like some material. It is foolish to place in the hands of a man methods and material beyond his scope. It is wise to place in that man's hands that with which he can do good work, and which he understands.

The retrograde changes in fibroids are very common. Some of the gentlemen present recently saw me remove large tumors that were perfectly healthy, apparently, but after incising them there was cystic degeneration. They are quite common, in fact, there are degenerations in about all. In early life the mental disturbance is very marked, and if you will only do your myomectomies after the hysterectomy you will soon convince yourself that this operation can not be complete, as you leave a small colony of fibroids. We must be careful in choice of method. I did an operation a few days ago which would have been a bad one if I had performed it blindly, or by the lower route. Jacobs gives nine injuries to the bladder, ureters and bowel in a series of about 400 cases. I repeat that these methods and instruments in the hands of one like Dr. Goffe, who is dexterous and knows how to use the instruments, are perfectly safe, as he gives it a very careful study, and makes a selection of his cases. The beginner, however, ought not to have instruments of that character in his possession without first serving an apprenticeship. in which he has done the operations under the direction of a man like Dr. Goffe. Again, in alluding to improvement, he refers first to adhesions and enucleation of a large tumor. If there be a large tumor, there also is disease of the appendages. We know perfectly well that those patients may be relieved by treatment, but a man might just as well say that we are not on this pier as to say that these cases with fixed appendages and adhesions are cured. Sometimes these patients go home with the pelvic basin filled above the ileopectineal line with pus. They are not cured because they are relieved.

Dr. E. G. Zinke, Cincinnati, Ohio—I have been very much gratified with the papers and the remarks of my friend Dr. Price, especially his remarks that this operation may be done in the manner described by Dr. Goffe and men of his skill, dexterity and experience. But when a man of Goffe's ability can execute such maneuvers as he described, how much more easily could he perform the same operation, with even greater perfection and much less danger to his patient, through the abdominal wall? If he can do his work so admirably through the vagina, I am sure he will be able to do it better and quicker through the abdomen. He says in his abstract that myomectomy is preferable to hysterectomy. That is true, but only to a certain degree, even "in all cases in which it can be employed." That is well put; it makes his position defensible. I venture to say that the cases are few, and by no means as frequent as he would have us believe. How many men are there who can positively tell that there are no serious complications even in small uterine fibromata? Sometimes, aye many times, when we feel pretty certain that there are no complications existing we find conditions least of all expected. That the operation can be done I do not doubt. Is it proper to do it? That is the question! I believe I can do it myself, if I tried. But why experiment? Because this pier and the hall in which we are assembled stand safely over the water, is it well to say: Let all houses be built over the ocean? I do not believe that the method of Dr. Goffe will be practiced extensively either in this country or abroad.

I am very sorry to hear that Dr. Boldt still finds a place for electricity in the treatment of tumors of the uterus. When I was abroad nine years ago, I saw Dr. Apostoli at work in his clinics for four weeks. It was there that I came to the conclusion that he was deceiving himself and thus misleading others. Spending also a good deal of my time with Dr. Péan, I asked him one day what he thought of Apostoli's method of treating uterine tumors. He said: "Electricity is a nice thing if your patient has plenty of money and is willing to pay you for your time. But, after all, when Apostoli gets through with his cases, I get them and operate on them."

Dr. W. H. Wathen, Louisville, Ky.—I am sorry that I did not have the pleasure of hearing all of Dr. Goffe's paper, but from the discussion I have learned the various points at issue. In the first place, I think we ought to call all those tumors myomata or fibromyomata because they are in their histogenetic origin myomata. In deciding whether a tumor should or should not be operated on, or whether the abdominal or the vaginal route, or both, should be adopted, we must consider the condition that exists in each and every case, because no two cases are exactly alike. Furthermore, we must consider the ability and the expertness of the operator. There are many cases that have no capsule at all. I removed one within the last few weeks, per vaginam, nearly twice the size of a fetal head, that I could not by any means have removed per vaginam, had there been several encapsulated hard myomata. In this case you could not find where the uterine tissue ceased and where the myomatous tissue began. It is not wise to attempt to do myomectomy in many cases. If we dissect a myomatous uterus we have removed we shall always find one or many tumors that we could not have found by myomectomy. The method of operating depends on several things; but I believe that the safest way to do is to begin an operation by the method that your better judgment dictates, but be prepared at the same time to complete the operation by any other method, if conditions arise that justify it. I sometimes purposely begin an operation per vaginam and complete it from above. A few weeks ago I removed a retroperitoneal myoma of large size that I could not have removed within three times the time had I attempted it from above, but by the operation from below I separated the vagina and the bladder as high as I could in a few minutes, and clamped and cut loose about 1½ inches of the lower part of the uterus. In every operation I begin through the vagina, no matter for what condition. I always have my patient prepared for an abdominal section and have the instruments that may be needed in readiness. Although I am prepared, it is unusual, however, when I begin an operation from below, that I am compelled to resort to the upper operation also. Frequently I begin the operation from below purposely with the determination to complete it from above. I believe that I can in some cases perform the operation in that way in less than one-half the time that I could from above alone. I believe Dr. Price could, in similar cases, by beginning below and completing the operation from above, operate in one-half the time that he now does by the abdominal route, and his patients would do better.

Dr. Charles P. Noble, Philadelphia—I was very glad to have this brought before the Association. I think the argument is in favor of the selection of myomectomy as against hysterectomy in suitable cases, that is, young women. Concerning the choice of the method I am not of the opinion of Dr. Goffe. It seems to me that the method which he advocates is more risky and more difficult than the abdominal route. In my own hands the vaginal route has been restricted to small submucous fibroids and small fibroids low down which can be removed without specially invading the uterine cavity. To remove a large tumor from below involves extra risks of infection and more traumatism than when it is done from above. I prefer the abdominal route. This is especially true when the tumor is larger, for then it is difficult to determine whether a myomectomy through the vagina is feasible. This whole subject of abdominal versus vaginal route has been talked over so long that little need be said about it. The greater facility in reaching the field of operation, and the greater certainty of asepsis and control of hemorrhage, are the reasons I prefer the abdominal route. In clean cases, where the proper ligatures have been used, I have seen only two cases of hernia in years. As a matter of fact, we do not see fibroid tumors unless they are causing symptoms. Patients who feel well do not consult a physician; therefore, a tumor existing without symptoms is not brought to the attention of the physician, and intervention usually can not be instituted as early as is desired. In a definite percentage of these cases sarcomatous degeneration has taken place, or a necrosis, myxomatous degeneration or a carcinomatous degeneration, which cause more deaths, many more, than the operation of myomectomy or hysterectomy.

Dr. G. B. Massey, Philadelphia.—If we are prejudiced in favor of one method of treatment our patient does not get what she pays for. We should give every case our careful, unprejudiced consideration in order to determine what method is the best to use in that particular case. I notice that professionalism in surgical opinion is very marked in these discussions, and I have also noticed an absence of it on the part of the same surgeons when the question referred to members of their own families. I was glad to notice the proper mention of electrical treatment by Dr. Boldt in his paper. Not every city in this country has been as alive to the advantages of electrotherapeutics as has New York. But Dr. Boldt does not go as far as he should. If I may paraphrase a remark made by a previous speaker; as surely as I am standing on this pier, so surely do I know of cases of fibroid tumors of large size, in fact, as large as my head that have disappeared. Now as to the so-called degeneration of fibroids into malignant growths, I think, in the light of our present knowledge, we should not call these degenerations. It is practically conceded at the present time that all cancers and sarcomas are infections, and we should therefore say infections instead of degeneration. The distinction is important, for it greatly lessens the necessary relation between the benign and malignant processes.

Dr. J. Riddle Goffe, New York City, closing the discussion—I do not mean to imply that my method is the only method; it is one method, and I think a superior one. The gentlemen who have discussed the paper are all right. I would do a laparotomy in case of a large fibroid extending into the abdominal cavity, and a vaginal myomectomy in a small fibroid. We must select our cases. In regard to the preference of vaginal over abdominal work I must insist upon its superiority because of the frequency and danger of ventral hernia following laparotomy. Dr. Noble flatters himself that he sees every case of abdominal hernia that occurs after his operation. I do not believe any operator sees the majority of the hernias following his laparotomies; the patient afflicted with a ventral hernia as a rule does not go back to the original operator believing it to be the operator's fault; she will go elsewhere; we see some of our hernias but not all of them, by any means.

In regard to the myomas gradually fading off into the tissues, and involving the larger portion of the uterus, that occurs occasionally and they are the cases in which hysterectomy is indicated. One point I made is important. Dr. Price criticises myomectomy as not insuring the removal of all of the tumors, and I admit that, but as I said in my paper, if you remove all that are discoverable and restore the uterus to its normal position, restoring thereby its circulation, you go as far as you can to prevent development of incipient foci. Dr. Porter spoke of my doing a vaginal fixation after myomectomy. That is not the idea. I shorten the round ligament inside of the pelvis instead of by the Alexander method.

Dr. H. J. Boldt, New York City—In regard to the definite percentage of degenerations, I would not for a moment admit it, because it is inconsistent with facts. There are cases which degenerate, but to say that there is a definite number is wrong. The experience of Dr. Price is not unusual; in operating on a case of fibroid, and on opening the tumor he found cystic degeneration.

In regard to the value of electricity, I only gave it an exceedingly limited field as a therapeutic agent, but for any one to say that it is of no service leads me to think that the observations have not been made as carefully as they might be. A certain number of cases will be symptomatically cured by electricity. It is true we need time to do it, but some patients will certainly be benefited. Dr. Goffe will pardon me if I say a few words on his paper. His words made an impression on me. In my opinion the main trouble in the cases he cited was not so much the neoplasm as the posterior adhesions, and after breaking them up the patients get along well. The greater majority of subserous tumors rarely give rise to any symptoms. The submucous tumors cause symptoms, and they can frequently be removed from below. In the great majority of instances where we have interstitial myomata the indications for the vaginal operation do not exist.

THE VALUE OF THIS SECTION'S WORK AND HOW TO ADVANCE IT.*

EDWIN ROSENTHAL, M.D.
PHILADELPHIA.

I was so deeply grateful for the honor done me, when I was chosen your chairman, that I promised myself, whatever work I might undertake, it should not only meet your approbation, but also enlist your interest to that extent as to make the work yours.

The opening of the sessions with an address carries with it a certain reponsibility, for in a measure, I am but the spokesman, and my utterances are but yours. Therefore, in presenting the result of my labors, I shall briefly preface my remarks with my reasons for pursuing such a topic.

The By-Laws say that the Chairman of each section shall prepare an address on the recent advances in the branches belonging to his Section, including such suggestions in regard to improvements or methods of work as he may regard important, and present the same to the Section over which he presides on the first day of its annual session.

It will be my earnest endeavor to merit the confidence you have shown, and I hope the deliberations of our Section may be a credit to us all, and its results prove the title of this address. Not only can my work become yours, but the result of our labors can with equal justice be claimed as belonging to the entire medical profession.

---

*Chairman's Address to the Section on Diseases of Children, at the Fifty-first Annual Meeting of the American Medical Association, held at Atlantic City, N. J., June 5-8, 1900.

Since pediatrics has become a recognized and distinct branch of medical science, those who have made it their life-work have left a distinct impress upon the general practice of medicine. So valuable has their work been that without these labors many modern discoveries in therapeutics would have remained unknown. And in the general advance that the year has shown the same workers have taken a most prominent part.

Of the many recent advances in medicine not one is as important to the pediatrist and the general practitioner as the clinical use of diphtheria antitoxin. It can be said that to the pediatrist belongs the honor of placing the serum where it justly belongs, and any improvement in its method of preparation, or in its use, should be investigated with more than passing interest, and the results should be known, thereby widening its field of application and increasing its life-saving power.

Diphtheria is pre-eminently a disease of childhood, the greatest frequency occurring between the ages of 2 and 10 years, and the proportionate number of cases diminishing very rapidly as the age increases. Its frequency in childhood; its constant presence in the cities of our land; the very accurate knowledge of its character in regard to its etiology, prevention and cure, which have become the common property of the layman; and above all, its being the most deadly and frequent disease that is met with by the pediatrist and the active practitioner, can be considered as prominent factors for its consideration in this address.

INVESTIGATING THE SUBJECT OF DIPHTHERIA.

Beginning my work, I found that during the year, various questions had arisen which were vital to the standing of antitoxin as a remedy in diphtheria, and to the users, if they be members of this Association or subscribers to the "Code of Ethics:" 1. The original discoverer of the antitoxin had obtained a patent for his product. 2. That at the Pharmacopeial Convention at Washington, the question of having a certain "test" embodied in the next revision of the United States Pharmacopeia had been voted down, thereby making the remedy uncertain, and instead of offering an inducement for the further improvement of its physical character, had permitted the chance of inferior products taking the same standing as the best, thereby lowering the standard of all. This question, however, is still open, hence a factor for further investigation by myself.[1]

COLLECTIVE INVESTIGATION BY OTHER SOCIETIES.

Antitoxin owes its present standing to the honest investigations of the pediatrist. Whilst many reports were received from numerous independent workers, and discussions were frequent in medical associations, no substantial results were obtained until collective investigations showed the truth or falseness of its specific value. The investigations are still too new, and their value is too well known, for me to repeat them, but they are sufficient to show me that such work was of the greatest importance, and in a measure gave me a method to further pursue my work.

OBJECT OF MY INVESTIGATION.

As there appears a certain reason that antitoxin should receive a thorough and complete investigation, and as this reason was not alone the clinical value of the remedy but also its ethical standing, I thought it proper to pursue my work in both directions, and not confine myself to the users of the serum, but to include its makers as well.

For the purpose of demonstrating the value of the remedy and to find out if it still retained the same virtues as at its beginning, early in January of this year I addressed the following communication to some 4000 teachers and leaders in medicine in this and other countries:

> *Dear Doctor:*—Will you kindly report, at the earliest possible moment, on the experience you have had in the treatment of diphtheria, with and without diphtheria antitoxin? If you can give me the number of cases of diphtheria treated by you without antitoxin, and the number of cases treated with antitoxin, with the results, it will be of especial value.
>
> Should you have no record of your cases, will you kindly advise what is your feeling toward the treatment of diphtheria with antitoxin?
>
> If you have any items of particular interest in your experience in the treatment of diphtheria (with or without antitoxin), I shall consider it a personal favor if you will report to me in full.
>
> It is my purpose to read a paper at the meeting of the American Medical Association, and I am asking the information from you since it will be of material assistance in securing data for my paper.
>
> Have you any preference as to what make of antitoxin to employ?
>
> Very truly yours,
>
> Edwin Rosenthal.

Briefly, I wished to obtain information as to the following:

1, what is the protective or immunizing value of diphtheria antitoxin; 2, what have been the results in general (private) practice with it; 3, what influence has the antitoxin exerted on the mortality records. The unanimity of evidence obtained regarding the value of antitoxin has been most remarkable. I shall not attempt to give full data from the replies, but will briefly summarize.

VALUE OF IMMUNIZATION.

I received many reprints and direct communications upon this question alone, and the consensus of opinion can be summarized thus: Antitoxin prevents diphtheria; if given early enough and in sufficient dosage, it prevents the appearance of the disease. If the serum be given as an immunizing agent, and in doses insufficient, it will modify, that is, prevent a graver manifestation of, the malady. If immunization be practiced, and the dosage be insufficient, that is, the disease manifests itself, it permits the application of a remedial dose, thereby preventing a more serous type. The statistical evidences were both pertinent and numerous; fol. 253, New York Health Department was most characteristic.

A very practical point brought out was the dosage. This was somewhat larger than we were led to believe. Five hundred units should be the dose, except in cases that have been exposed for a number of days or where the vitality or strength is seriously impaired, and natural immunity consequently nil. In such cases, irrespective of age, from 750 to 1000 units is a more certain prophylactic.

RESULTS IN GENERAL PRACTICE.

I was deeply impressed in receiving letters from physicians who have passed through serious epidemics of diphtheria, and know from practical personal experience the changes brought about since the advent of antitoxin. I may add that some of my correspondents have given information regarding other plans of treatment with results, and that if a complete compilation were made, the general result would be so conspicuously in the favor of the antitoxin, that its simple repetition would suffice. My replies were of three kinds: One set I should class as consultants, teachers or writers on this subject; the second set were from active family doctors, and the third were from those connected with hospitals or other institutions in which diphtheria was treated. As the first and last class could not in truth answer the question as above, I gleaned from the mass, only those whom I deemed answered my purpose, to wit, the active practitioners, and present the result as follows:

---

[1] See letter from Parke, Davis & Co., from whose reply I obtained the knowledge.

Total number of physicians reporting.......673
Number favorable to antitoxin.............622
Number expressing no opinion.............. 26
Number opposed to antitoxin.............. 5

ANTITOXIN CASES.

Total number of cases of diphtheria reported......12,375
Recoveries 11,727
Percentage of mortality, 5.23.
Number of cases reported without specifying serum..5191
Recoveries 4897
Percentage of mortality, 5.28.
Number of cases reported with serum prepared by Parke, Davis & Co. 753
Recoveries 699
Percentage of mortality, 7.15.
Number of cases reported with serum prepared by Mulford & Co............................ 6325
Recoveries 6065
Percentage of mortality, 4.11.
Number of cases reported with serum prepared by Behring, Aronson, Roux, and various boards of health 106
Recoveries 96
Percentage of mortality, 9.5.

These results as just given are perhaps a repetition of what is now so universally known. This, however, teaches us that the antitoxin still retains its position, and that the results now are not different from what they were at the beginning. I might add that some of my replies were simply a sentence placed at the end of my letter of inquiry, short and to the point. An example of many is as follows: "No question for further debate; its position is settled."

THE INFLUENCE ON THE MORTALITY RECORDS.

To obtain accurate information upon this point, I called to my aid every health officer in American cities having an organized bureau of health as well as hospitals for contagious diseases and pest-houses. I also wrote to foreign countries, and to such institutions or individuals as I had learned of in my readings or otherwise. The following letter was sent to each:

Dear Doctor:—Will you kindly furnish me with the number of cases of diphtheria and the mortality of the disease from 1885 till 1899, inclusive? If you do not have the statistics for each year, kindly furnish the years for which statistics are available. Should you have no record of the cases, will you kindly advise, from your experience, what value you consider antitoxin possesses?

If you have any items of particular interest in your experience in the treatment of diphtheria (with or without antitoxin), I shall consider it a personal favor if you will report to me in full.

Have you any preference as to what form of antitoxin to employ?

My object in writing you is to secure positive and accurate information upon the treatment of diphtheria, with and without antitoxin, as it is my purpose to read a paper before the coming meeting of the American Medical Association, and your data will be of great benefit to me if you will kindly furnish it.

Very truly yours, Edwin Rosenthal.

One hundred and fifty-seven cities replied. A summary reveals the following figures:

Number of cases previous to the serum period. 183,256
With a mortality of 38.4 per cent.
Number of cases since the antitoxin period... 132,548
With a mortality of 14.6 per cent.

The latter were not all treated with serum; in computing those cases treated with the serum alone the mortality was 9.8 per cent. A very characteristic reply, I append. It comes from Basel, and was sent me by Prof. E. Hagenbach-Burckhardt, and was translated by himself, and is so clear and concise that it is self-explanatory:

Year.	Without serum		With serum		Total.
	Cured.	Died.	Cured.	Died.	
1888	22	9	..	..	31
1889	20	18	..	..	38
1890	14	17	..	..	31
1891	20	11	..	..	31
1892	18	14	..	..	32
1893	20	17	..	..	37
1894	20	10	3	2	35
1895	..	2	87	17	106
1896	..	..	54	15	69
1897	..	1	48	3	52
1898	1	..	52	4	57
Total	135	99	244	41	519

Others were quite as complete, and were instructive to us, as showing how quickly such statistics could be obtained, and how the foreigners assist the authorities by keeping accurate records. France, Italy, Germany and Hungary were the most accurate, and I may especially mention the work of Egidi in Rome, Trumpp in Munich, and Bokay in Budapest as among the most prominent factors in the statistical study of diphtheria abroad. Another very pertinent and withal useful fact I obtained from my foreign correspondents and that was, that the unfavorable "serum" symptoms first noted in the use of the remedy, such as joint pains or swellings and urticarial rashes were not so frequently seen, and that latterly they were disappearing, so that an utter absence of all unfavorable manifestations of the remedy was to be expected in the future.

Of the method of using the antitoxin, the summary shows the following as the latest conclusions: When called in the early stages of the disease, and the symptoms are favorable, never administer less than 1500 units. Where, however, the "laryngeal" form threatened, it is never advisable to employ less than 2000 units. Should the type of the disease be severe, 2000 units should be the minimum commencing dose, and if of the laryngeal form, 3000 units should be the commencing dose. In every instance where favorable action does not manifest itself in 6 to 10 hours, a second injection should be made of double the number of units of the primary injection.

To what quantity can the antitoxin be used? Dr. Rosa Engelmann in her reply adds: "Would say, further, that I now use much larger initial and subsequent curative doses. I recently used 20,000 units in 7 days in one case." I was pleased to learn from this that others used large doses besides myself.

THE ETHICAL STANDING OF THE ANTITOXIN.

As the question of the antitoxin being patented by one of the originators has been the subject of journalistic discussion, much to the ethical standing of the remedy, I was prompted to investigate this point by writing to the most prominent manufacturers in this country, briefly stating my desire to have the question of "Ethics" brought prominently before this Section, prefacing my letter by my reasons for writing, and adding that, we, who belong to the American Medical Association and subscribe to the "Code of Ethics," could not in honor use any drug that carried with it the taint of fraud. The following letter was sent to each:

Gentlemen:—In my address before the Section on Diseases of Children of the American Medical Association, I wish to place antitoxin upon the same footing as any other well-known remedy, and by this address I wish to have the indorsement of my Section, so that it should be placed in the United States Pharmacopeia.

For the purpose of showing its value from the standpoint of the physician, I have written, and have received replies from almost every well-known user of the remedy, in this and other countries. Through these I wish to show:

1. Its influence as a specific in diphtheria.
2. Its influence on the mortality records.
3. Its influence as an immunizing agent.

Now since a question has arisen regarding a "patent" and as it is essential for any one connected with the American Medical Association, or who subscribes to the "Code of Ethics," to reject any remedy whose name can be questioned, I wish to have the opinion of the manufacturers regarding the ethical standing of this drug. Will you, therefore, as a manufacturer, reply to the following questions, and in doing so, in such a manner that will be concise, and in such shape that I can append your reply to my thesis:

1. Have you any copyright, patent, or secret in the name "diphtheria antitoxin?"
2. Do you place any secret on the method of its preparation?
3. Commercially, you place it, as any well-known alkaloid —quinin or the like—the value of the remedy depending upon the reputation of the manufacturer, and sell it only through the ethical markets of the world.

I received a most satisfactory reply from each, and I can do no better than read here the replies. The first was from H. K. Mulford Company, and is as follows:

Dr. Edwin Rosenthal, Chairman, Etc.:

Dear Doctor:—In reply to your communication of the 22d inst. we advise that our methods for the preparation of antitoxin are, at all times, open to members of the medical profession. As a matter of fact, we cordially invite physicians and health authorities to visit our laboratories and thoroughly acquaint themselves with the methods by which diphtheria antitoxin and our various products are prepared.

We do not, nor have we ever attempted to secure a copyright, patent or trade-mark for diphtheria antitoxin; there is no secret in its method of manufacture or preparation, which is upon a higher plane even than the manufacture of chemical and pharmaceutical products, because we prove, by our standard of testing, the exact number of antitoxin units—immunizing or protective value) that each c.c. of serum contains.

Antitoxin is supplied to physicians and druggists, and we introduced the custom of protecting the product by allowing physicians and druggists to exchange for a fresh supply any lot of antitoxin not used within the time specified on each label. In addition to this we have established the system of absolute standardization of strength, giving the number of units to each c.c. of serum, as well as the aggregate number of units contained in each package.

In this connection we desire to extend to you personally, and to the members of your Section, as well as to the members of the American Medical Association, a most cordial invitation to visit our laboratories and acquaint yourselves with the methods of preparation, not only of antitoxin, but also of vaccin and our pharmaceutical products.

Your are entitled to special thanks, not only by the members of your Section and the American Medical Association, but by all physicians, for the efforts you are making to secure absolutely reliable reports concerning the value of diphtheria antitoxin and its influence upon the mortality rate.

Very truly yours, H. K. Mulford Company,
H. K. Mulford, Vice-President.

The second letter was from the firm of Parke, Davis and Company of Detroit, and is as follows:

Dr. Edwin Rosenthal, Chairman, Etc.:

Dear Sir:—We have the honor to acknowledge receipt of your favor of the 22d inst., raising certain questions with regard to the ethical character of antidiphtheritic serum, and it gives us much pleasure to return an unequivocal answer to each of your inquiries.

1. We have no copyright, patent, nor secret protection in conjunction with the name "diphtheria antitoxin." From the time when we began producing and marketing the serum our product has been entitled Anti-Diphtheritic Serum. This is a scientific and descriptive appellation, strictly in harmony with the rules of rational nomenclature, and any producer of diphtheria antitoxin is free to use it.

2. We have no secrets in our methods of producing and testing antitoxin. We have repeatedly published the details of our work, and they are, moreover, open to the personal inspection of any reputable pharmacist or physician.

3. To your third question we unhesitatingly reply in the affirmative. We market our antidiphtheritic serum precisely as we exploit quinin or any other of the well-known alkaloids.

The only protection of any kind or character which we enjoy —and even this is in no sense proprietary—accrues to us from the presence of our name on the labels of the vials which emanate from our laboratory.

We sympathize warmly with your wish to have antitoxin placed upon the same footing as any other well-known remedy, and, without caring who knows it, we affirm that in our judgment the recent Pharmacopeial Convention at Washington made a mistake when it voted down the proposition to have a test for antidiphtheritic serum embodied in the next revision of the United States Pharmacopeia. We yet hope that the license and latitude accorded the revision committee of twenty-five, who are the real authors of the pharmacopeia, will prompt them to adopt and publish an official test for diphtheria antitoxin. We need hardly explain to you that such action on the part of the revision committee is of no selfish or commercial interest whatsoever to the manufacturing houses. From the sordid and commercial view-point the manufacturer of antitoxin need not care a fig whether the serum is adopted by or excluded from the Pharmacopeia. But every honorable house which aspires to be something more than a huckster of medicinal products exhibits at least some concern for the interests of medicine, science and humanity, and it is this consideration which pleads powerfully for such a test in the Pharmacopeia as shall define with precision the meaning of the word "unit," and as shall tend to shield profession and public from the disaster of an inferior or impotent serum.

Pray command us freely if we can give you any further information, and believe us, Very sincerely yours,
Parke, Davis & Co.

From the latter letter you can well understand the value of the thorough safeguards that should be thrown around the remedy, and how necessary it is that its remedial character should be above reproach. Receiving this information you can well understand why I undertook the task just closed, the reasons and the results I wish for.

The history of antitoxin is inseparably connected with pediatrics. To the fearless and scientific labors of the pioneers were due the first tests undertaken, and through the collective investigations of the associations was the true position assured. Surely, it still belongs to the pediatrist to see that no injustice be done either to the drug, or its makers; and the question of its admission with all the tests necessary, to the pharmacopeias of the world should enlist the support of all.

REASONS OF THIS COLLECTIVE INVESTIGATION AND ITS OBJECT.

That there still exist physicians whose knowledge of the progress of medicine is in abeyance, and whose position in our midst is a factor of much harm, makes the question of placing antitoxin on our list of remedies—like quinin or the various alkaloids—a very pertinent one. It is not necessary for the progressive, honest and ever-seeking doctor to be told the virtues of any new drug; for he is always on the lookout for all that aids him. But for the slow, undecided and unbelieving one, it is a very essential thing to place good remedies within his reach. The practitioner whose only progress is the United States Pharmacopeia should be assisted in his search for knowledge; and with this in view, our help can not be otherwise than in the right.

In the preparation of the scientific program, I was very much elated at the strides that pediatrics had made in the last decade. It has grown to such dimensions that it is now capable of specialization. Having this in view it has been my pleasure, with the assistance of our good and very obliging secretary, to go over the field thoroughly, and to invite, for our benefit, such pediatrists as had made certain diseases their special study. Nor did we limit ourselves to our own knowledge, but asked the assistance of those we knew, and thus completed each group by the addition of well-known authorities residing in other countries. The result of our labors we present to you in the form of our program, which we have divided into sessions, so combining the workers as to make a happy whole. To-day we have a sesion devoted to the consideration of the feeble-minded and we have specialists to address us who have devoted their lives to this work. To-morrow morning we take up the consideration of infant-feeding; in this group we have not only included the masters in the art of artificial feeding of the infant, but we shall have with us one of the foremost chemists and bacteriologists in the land, the discoverer of the poisons in the milk. In the afternoon we shall consider contagious diseases, and following out our plan of seeking the original workers in this field, we shall have Koplik—whose work in measles is so intimately connected with his name—with an original paper on rötheln; and Schamberg, with a paper on an entirely new investigation in scarlatina; whilst we have invited well-known authors for the discussion. On Thursday morning diseases of the blood and the circulation will have our attention: while in the afternoon the session will be devoted to the consideration of school children. To this session I have invited some well-known educators, as well as physicians who have devoted their time to special studies in this direction—Lautenbach on the ear, Fenton on the eye—for the discussion; while Dr. Spiegle, as physician to the Girls' Normal School in Philadelphia, will read a paper of distinctive interest to us all. Friday we have left for surgical subjects; and following closely the same general plan, our work will close with Dr. Valentine's paper on circumcision, an operation the technique of which is his own, and which is now connected with his name. Hence we may call his an original subject. With such a program as this, surely all will be satisfied, and it may be taken as a distinctive proof of progress that in this Section there is a feeling that one of our members should be appointed to deliver the yearly oration.

There is one point that is demonstrated by this program, and that is, the amount of labor and care such work entails. Even with all this work, the desired result—the universal interest and presence of all the members—may not be obtained. If the meetings be not well attended, then must we say our result is not satisfactory. For this reason, and because I have twice had the experience in getting up a program for this Section, my thoughts were again recalled to the By-laws of the Association, and the chairman's duties.

NEXT YEAR'S PROGRAM—TYPHOID FEVER.

A duty reposed in the chairman besides this address is to advise, to suggest an improvement in our method of work. I have given this my long and earnest thought, and have concluded that to keep the interest of the Section constant is to suggest such work as would become the purpose of the members, and would result in the greatest value, not only to the Section, but to the whole profession, and require the personal interest of all. Such an object as this I must confess is not new, as witness the collective investigation of other associations, but its application to our Section has never been attempted, and its trial for the new chairman and the next meeting should greatly add to the interest of a coming meeting and invite the attention of all. I would suggest that at this meeting the Fellows should adopt the *investigation of a disease or its treatment*, and the chairman should appoint—or it may be the pleasure of the Section so to elect—a number who shall become the committee, and who by collective means, as well as by personal investigation, shall present at the next meeting the result of a year's work. The work with which one is most familiar is the work about which he can best speak A chairman naturally imbues such advice with a reflection of his personality. The application of remedies for an expectant or specific effect is the natural sequence of diagnostic skill. If one becomes a master in the art of diagnosis, he should equally bend his thoughts and apply his capabilities for the relief or cure of what he sees. New treatments and new remedies are always successful in the hands of one who first advised or originated. When, however, a remedy becomes universally successful its standing is assured; it ceases to be grouped amongst the expectants, and becomes a specific, and as such should receive an honorable place in our therapy. Antitoxin has passed through all the stages and now ceases to be debatable. Diphtheria has lost its terrors, and has become a preventable as well as a curable malady. As it was mainly due to the pediatrist to present such results, it is natural for the world to look upon any work thus undertaken with more than passing interest and to keep up the reputation thus gained, the work can not be otherwise than of the highest order. With the reflection of our past work let us take up our future work with the same desire, and turn our thought to another disease that, equally with diphtheria, has received the attention of the layman. I have reference to typhoid fever, a disease, the presence or absence of which from any community is a criterion of that city's culture, civilization, and I might add, its political purity. Its presence shows not only the ignorance of the powers that be, but the negligence of the responsible ones. To the sanitarian its presence causes shame, and its absence brings pride. We owe—among other blessings— to the bacteriologist the knowledge of its causative factor, and equally to him the knowledge of its prevention. As the knowledge is so universal that is is a "water-borne" disease, it should be a badge of shame for any board of health to order the rule, "Boil your drinking water." I unfortunately reside where the powers that be are callous to the cry of the people, and the slaughter of the innocents goes on. We, as a representative body, can not prevent, or even seek to do so—for, strange as it may seem, if we try to prevent or wish to alter these causal conditions, our purpose is looked upon as mercenary, and our object personal gain—we can only hope to stay its ravages when it appears. As this disease, with such constant dangers, and beset with such numerous complications, always exists in a community, our purpose to study its treatment and to present the one that will give most promise of good will of a certainty receive universal commendation.

It appears to be a mistaken belief that typhoid fever in children is of a milder type than that in the adult, and that the prognosis is invariably better. Probably for this reason so very much has been written about the treatment as to add only to the confusion and disappointment. If we, as a body, can for our task take up the treatment that can give the best promise of success, and show the truth or falsity of each, our work will be of the greatest value. It should not be forgotten that the opportunities that many of us have are greater in proportion to what fortune has given to others, and the work that the best versed in treatment presents is quickly taken up by the less fortunate of his brothers. For this reason our work will be watched for and followed, and if of value, the commendation given us will be sufficient payment.

For the purpose of merely giving an outline of how the work should be pursued, I present my methods, in preparing the earlier part of this address. In collective investigations each one takes a part. The work belongs not alone to the one that undertakes, but to the one that assists as well.

Typhoid fever has been investigated by many associations, but in their work they have taken up the disease as a whole, and have not specialized. Naturally, the subject is so large that their influence is not so far-reaching as it would be if but a certain part were considered. Note, diphtheria, for example. The collective investigation on the subject of scurvy gave extraordinarily good results as regards infant-feeding, and cleared up the probable causative origin. As examples of this mode of preparing a program, I need but point to the last meeting of the New York State Medical Association, the sixteenth annual meeting. A whole session was devoted to the consideration of typhoid fever.

The treatment of typhoid fever in children should resolve itself into two main questions: 1. Is there any specific method of treatment? 2. Should the treatment be symptomatic only? Specific treatment is the one that will naturally give the most interest, and may be divided into: 1. The so-called antiseptic treatment; 2, the so-named abortive treatment known as *a*, the Woodbridge, *b*, the Viskolein, *c*, the serum treatment, *d*, the nuclein solution and cupric arsenite. 3. The use of the so-called antipyretics of coal-tar derivation, as antipyrin and thermol.

The symptomatic treatment can be studied by the Brand method or any of its modifications, the use of drugs, or the use of water internally, as the Vichy, bitter waters, Apollinaris waters, Apenta and the like.

The outline of a task for others to follow is very simple, but may not find favor with those who wish to pursue it, so that if such a program as this be the order of the new chairman, it should be left to him to choose the method most suitable, most convenient, and, in his opinion, concise. Furthermore, no restrictions should be placed upon the means employed; the object to be attained is sufficient. Work in this direction, especially with remedies supposed to have specific value, is always of vital interest, and always receives the attention it deserves. I ask you all to kindly read the *Pennsylvania Medical Journal* for April of this year, and note the work of Dr. J. C. Wilson, on the treatment of typhoid fever, presented before the Medical Society of the State of Pennsylvania. Such honest work as this, even if the results be negative, always receives the thanks, not only of the workers in our midst, but of all, and should spur us on to greater effort.

The chairman of the Section can allot a special session, and choose from our midst those who by training and experience are the better judges. We need not go out of our Section for this. We have Morse, Griffith, Tuley, Cotton, Wilson, Graham, Northrup, Vaughan, and so many that a repetition would be telling a list of members. From these the chairman can name a committee, if you like, to whom we all can report. They should be the ones to discuss the subject at the next meeting, and their time should be unlimited, and their report should be the report of the Section.

Work like this will hold the members together. When we adjourn we do not leave with the idea that our work is finished for the time or until we are called together again. But the work goes on and the existence of the Section continues. The interest is kept going, not being confined to the officers alone, but each member knows and feels that he is taking part. A letter of inquiry can be sent to each, with the remark that the final report should be sent in time to be collated. If by such work as this we can claim the saving of one life, then we can prove to the world the necessity for our existence, and our labors will not have been in vain.

517 Pine Street.

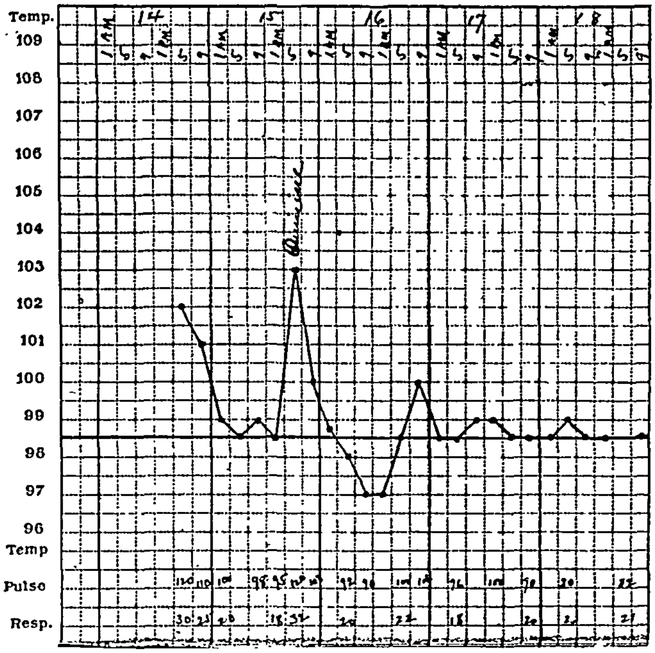
FOUR CASES OF MALARIA ASSOCIATED WITH ACUTE ABDOMINAL PAIN.*

JOSEPH A. CAPPS, M.D.
Instructor in Medicine, Rush Medical College.
CHICAGO.

For the privilege of reporting the following cases from the wards of the Massachusetts General Hospital, I am indebted to Dr. E. S. Cutler, of the visiting staff.

Case 1.—A married woman of 25 years, living in Arlington, Mass., entered the hospital July 14, 1896. Her father died of pulmonary tuberculosis. Catamenia was always normal. She has one healthy child. Until recently her health had been excellent, with no history of malarial fever nor any of pelvic disease.

For three weeks she had not felt as well as usual, and for ten days had suffered from malaise, headache, occasional vomiting, chilly feelings and backache. During the preceding five days she had been confined to bed with daily fever. Two days before admission, upon attempting to walk, she was taken with a chill and vomiting, accompanied by severe pain in the lower abdomen. Since then all food had caused a sense of fulness and soreness in the epigastrium. On the afternoon before admission she had fever, but no distinct chill. She complained also of sleeplessness, loss of appetite and chronic constipation.



Case 1.—Malaria, double tertian.
Blood: Hemoglobin, 70 per cent.; reds, 4,100,000; whites, 5800.

The patient was sent to the hospital for surgical interference with the diagnosis of acute salpingitis.

The physical examination showed a body well developed and nourished, face pale, tongue moist and clean, pulse rapid and of low tension. On the upper lip were several herpes vesicles. The lungs were normal. Over the base and apex of the heart a soft systolic murmur was heard and was not transmitted to the axilla. The spleen was palpable and its area of dulness enlarged. There was *no especial tenderness of the abdomen to pressure.* By vaginal examination the uterus was found retroverted and on the left side there was a slight resistance and tenderness. The urine was normal and failed to give the diazo-reaction. In the evening the temperature reached 102 F., pulse 20, respiration, 30.

No actual chill occurred on the first day, but the blood drawn at the height of the fever showed a few plasmodia malariæ. The organisms were all intracellular, and contained fine pigment granules in active motion. The hemoglobin was 70 per cent., red corpuscles 4,100,000, white corpuscles 5800.

At 3 p.m. the next day she had a chill, followed by vomiting, sweating and a temperature of 103 F. During the paroxysm and for several hours afterward there was severe abdominal pain, not sharply localized. Again the plasmodia were seen in the blood and twenty grains of quinin were given in four divided doses every half hour. The fever fell and the pain gradually died away. No recurrence of headache, chill, fever, nor abdominal pain took place, and on July 29 she was discharged well.

The daily intermittent fever and the type of organism demonstrated this to be a case of double tertian malarial infection. The pain came on with vomiting during a paroxysm and persisted for several hours afterward. As to localization, the pain was referred at first to the lower abdomen, then to the epigastrium, later to the whole abdomen.

Case 2.—A widow, 31 years of age, admitted July 16, 1896. Her father and brother died of phthisis. Seven years ago while living in Hyde Park, Mass., she had malaria. For a year she had been subject to indigestion, and eight months before vomited about a teaspoonful of bright blood.

The present illness began three weeks previously with headache and frequent vomiting, which for the last ten days had been daily symptoms. For six days she had been in bed because of weakness, frontal headache, vomiting, fever and pain in the epigastrium. Four days before entrance these symptoms became more pronounced, especially the epigastric pain, which lasted all day and required morphia. That afternoon a chill came on, followed by sweating, fever and vomiting. The following day she had no chill, but the epigastric pain and headache continued. Two days previous to admission she was taken with a chill, followed by fever, sweating and abdominal pain. The next day there was no chill and no discomfort aside from the persistent pain in the upper abdomen. On the morning of the day of entrance she was delirious, had headache, vomiting and cutting pains in the epigastrium, and at 10 a.m. a chill, succeeded by fever and sweating.

On acount of the acute abdominal symptoms she was brought to the hospital by her physician as a surgical emergency, the provisional diagnosis being either gallstone colic or gastric ulcer with perforation.

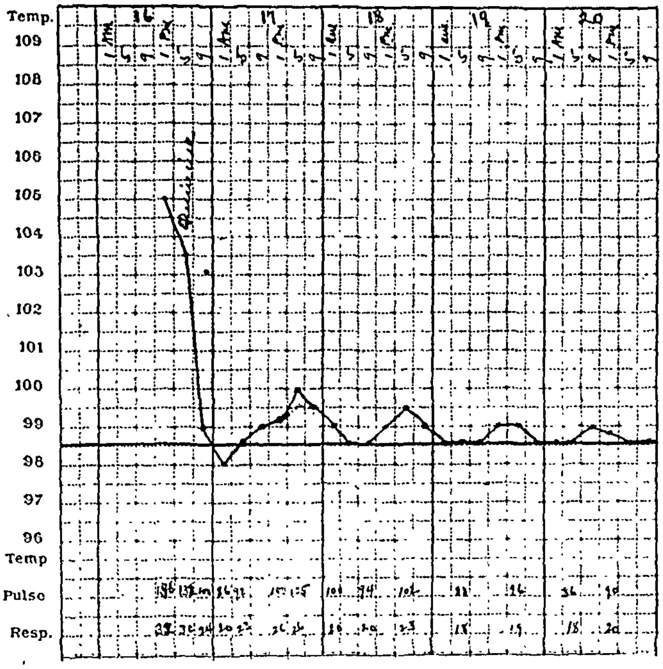
Upon examination she was found to be in good flesh, dark skinned with a yellowish tinge to the sclerotics. The knees were drawn up as if from pain. Nothing abnormal was found in the heart and lungs. The edge of the spleen was felt. Over the epigastrium there was great tenderness to pressure, which was not localized to one spot; otherwise the abdomen was negative. At 1 p.m. the temperature was 105 F., pulse 132, respiration 30.

---

*Read at the Chicago Society of Internal Medicine, May 31, 1900.

The blood analysis gave hemoglobin 64 per cent., red corpuscles 3,900,000, and leucocytes 8900 in a cubic mm. This absence of a leucocytosis was such a strong evidence against any acute inflammatory process that a specimen of fresh blood was examined for plasmodia malariæ. A few organisms were found, but only after an hour's search in three different drops. These, however, were typical tertian forms with pigment in active motion.

At once twelve grains of quinin were given in solution, and five-grain doses repeated twice at intervals of an hour. Within two hours of the first dose she became cinchonized, and in three hours was practically free from the pain. The temperature thereafter was normal, except for a rise to 100 F. on the second day. The epigastrium remained somewhat sore and tender for several days, but no real pain returned. After nine days of treatment she was discharged in good condition, although still weak and anemic.



Case 2.—Malaria, tertian.

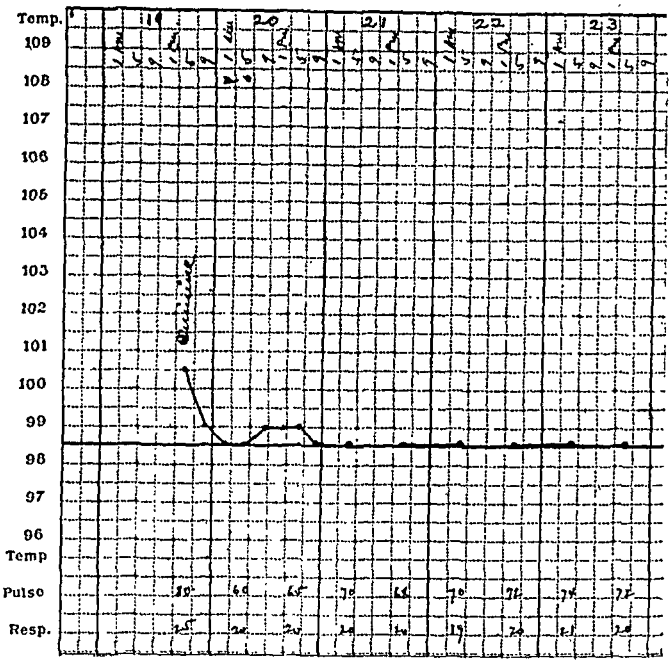
Blood: Hemoglobin, 64 per cent.; reds, 3,900,000; whites, 8900.

In this instance there is no apparent relationship between the vomiting and the pain, since the pain continued with greater severity during the intervals between vomiting attacks. It is to be noted that the seat of pain was invariably the epigastric region.

Case 3.—This was a woman from Brighton, who was admitted July 19, 1896. Two brothers died of "quick consumption." Catamenia as a rule was normal. She had one son living and one dead. When she was last with child menstruation continued the first three months of pregnancy. Her most recent period was of three days' duration, instead of six, as was usual, and at that time several blood-clots of offensive odor were noticed.

Six years ago she was run over by a carriage and her right hip stepped on by a horse. Nearly ten weeks of treatment were necessary before she could walk about again and the right side of the pelvis has always remained a "weak spot." Since an attack of sunstroke five years ago, when unconsciousness lasted seven hours, she had been subject to frontal and occipital headache. Two years ago, after her first confinement, the uterus was prolapsed but was restored to position. From the time of her last confinement, ten months ago, she has been troubled with more or less pain in the right iliac and pelvic regions.

June 17, about one month before admission she had for the first time a chill and fever. Similar attacks came on June 18 and 20, when she began to take daily small doses of quinin. On the 22d another slight chill occurred. After an interval of twelve days, in which quinin was regularly administered in small quantities, she again had a chill with fever following it. No abdominal symptoms were present in any of these attacks. Four days previous to entrance she was compelled to go to bed on acount of cramp-like pains in the lower abdomen and nausea without vomiting. There was no chill nor fever. The next day the pain was more severe, localized in the right iliac region and relieved only by morphia. Intense frontal headache was also present. Two days before entrance she was weak and exhausted from the abdominal pain and fainted away several times. In the afternoon she had a severe chill, frontal headache, vomiting and fever. The day following she was free from all symptoms, save a soreness in the right iliac region. During the day of admission she complained of frontal headache and frequent twinges of abdominal pain and toward evening became chilly and nauseated.



Case 3.—Malaria, tertian.

Blood: Hemoglobin, 62 per cent.; reds, 3,610,000; whites, 5000.

The physical examination showed a delicate, pale, thin woman with a sallow skin. Her expression was one of pain, but not pinched. The thoracic organs appeared normal. The area of splenic dulness was enlarged and the edge of the spleen was felt with some difficulty. The abdomen was tender and resistant over the right iliac region. Vaginal examination revealed a large lacerated cervix and a mass in the left ovarian region, not tender; also a distinct resistance in the right ovarian region with considerable tenderness. The temperature was 100.5 F., pulse 80, respiration 25.

The diagnosis had been made of extra-uterine pregnancy, and like the preceding case, she was brought to the hospital for immediate laparotomy.

That evening a small number of fully developed tertian malarial organisms were found in the blood in active motion. The count of white corpuscles was 5000, red 3,610,000, hemoglobin 62 per cent. Twenty grains of quinin were given in four doses at half-hour intervals.

After this no chill nor fever occurred, while the pain gradually diminished. A week later, however, another severe attack of pain in the abdomen came on, which was greatest in the splenic region and of less degree in the right iliac region. Chilliness accompanied the pain, but no true rigor nor fever. No leucocytosis was present and no parasites were discovered in the blood. A pelvic examination revealed nothing that explained her symptoms. Subsequently under daily treatment with iron and quinin her convalescence was rapid.

January 1, 1897, she wrote that the soreness remained in the right pelvis, but no further chills nor severe attacks of pain had taken place.

In this case there was a chronic underlying condition in the pelvis that probably caused much of the pain, but it was the supervening malarial infection that gave it such an alarming aspect. It would seem that the malarial poison converted a chronic pain and soreness into acute pain, a theory that is borne out by the subsidence of the pain under quinin. Here again the low leucocyte count was of much value in ruling out extra-uterine pregnancy or a fresh pelvic peritonitis. The pain was most intense in the right inguinal region and slight over the spleen. It was not influenced by vomiting.

Case 4.—A woman of 30 years, living in Somerville, entered the hospital August 6, 1896. Her family history was good. For several years she was troubled somewhat with dyspepsia; otherwise her health had been excellent.

Three weeks before admission she was suddenly taken with slight diarrhea and cramp-like pains in the lower abdomen, chiefly on the left side. Soon vomiting came on and continued at frequent intervals for twenty-four hours, when it gradually ceased. The bowels again became regular in a few days, but a dull aching pain persisted in the lower abdomen. On August 3 she had chill, associated with headache and vomiting. On August 5 the same symptoms recurred, but she suffered mostly from the severe abdominal pain, this time localized in the right iliac region. The pain slowly eased up after the paroxysm until another chill came on the following evening with the same acute pain.

This patient was admitted to the hospital as a case of appendicitis.

The physical examination at the time of entrance was negative, except for a moderate degree of tenderness in the lower abdomen, not especially marked over McBurney's point, and for an enlarged area of splenic dulness. The temperature was 103 F., pulse 100, respiration 30. Blood examination: hemoglobin 73 per cent., red corpuscles 3,820,000, white corpuscles 3600. The urine gave the diazo-reaction.

After the chill a few pigmented tertian forms of the plasmodium malariæ in active motion were found in the blood. With the falling temperature five grains of quinin were given and repeated three times at intervals of thirty minutes. Subsequently her temperature remained normal and every symptom disappeared completely. Neither the vomiting nor the diarrhea explains the pain, for it preceded the former and recurred when the bowels were acting normally. Localization was over the lower abdomen, particularly on the right side.

It is to be observed that in all these cases:

1. There were intermittent fever, nausea and vomiting and enlargement of the spleen.

2. There was acute abdominal pain of such intensity that exploratory laparotomy was considered by men of experience.

3. The acute pain subsided along with the fever and with the other symptoms after the administration of quinin.

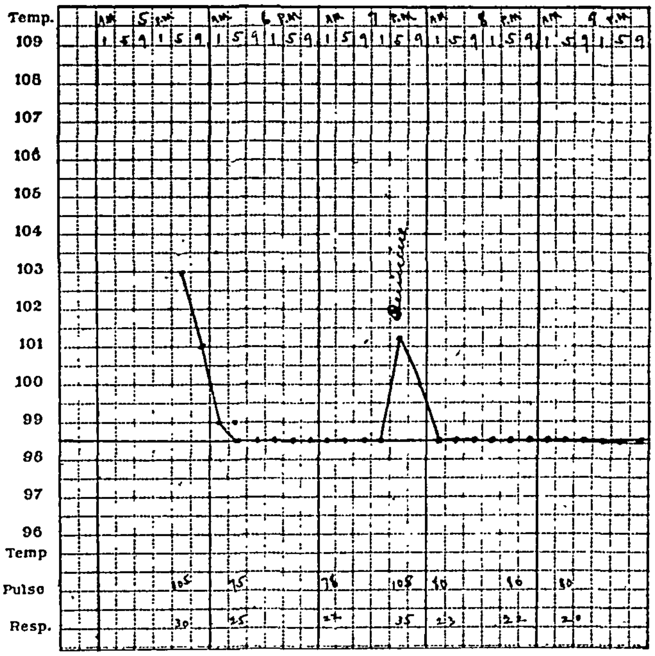
4. Typical intracellular forms of the tertian parasite of malaria with motile pigment granules were present in the peripheral blood, but were never very numerous.

5. Leucocytosis was invariably absent.

6. A considerable degree of anemia existed of the secondary type.

The cause of the abdominal pain was not at first apparent. The explanation does not lie in the vomiting and the incident straining of the abdominal muscles, for the pain often preceded and outlasted the vomiting, and was also present independently. The pain must, therefore, be attributed to: 1, some co-existing disease; 2, a neuralgia from the malarial poison, or 3, both combined.

In two cases local lesions were found that might have caused some pain, but not of such acute character. Moreover, a lighting up of an old pelvic cellulitis or salpingitis sufficient to cause an acute attack of pain, fever and gastro-intestinal disturbance would always produce a leucocytosis, while these cases had counts of 5800 and 5000, respectively, which are even lower than normally.



Case 4.—Malaria, tertian.

Blood: Hemoglobin, 73 per cent.; reds, 3,820,000; whites, 3600.

The chronic disease may be considered in the rôle of a predisposing condition, rendering the part peculiarly susceptible to the malaria poison. The most rational supposition is that the pain is a neuralgia caused by the malaria toxin in the blood.

COMPLICATIONS IN THE NERVOUS SYSTEM IN MALARIA.

Since Laveran's discovery of the specific organism, the tendency has been steadily to decrease and limit the number of complications of malaria, because many affections formerly called malarial do not afford the only final and conclusive proof of the disease, namely, the presence of the parasites in the blood. We have, however, abundant indisputable evidence that the malarial poison directly and indirectly affects the nervous system.

The brain, spinal cord, or peripheral nerves may be involved. Authentic cases of delirium, hemiparesis, monoparesis, aphasic disturbances, symptoms resembling those of multiple sclerosis and ataxia, have been reported, but our subject confines us to complications of the peripheral nerves.

Neuritis and Neuralgia.—Peripheral symptoms may be motor or sensory, the former being rare and appearing in connection with neuritis. Many cases of malarial neuritis are on record, but those in which the organism has been found in the blood are strikingly few. Among the most reliable observers is Glogner,[1] who describes six cases of multiple neuritis, four of which developed during the infection, while the parasites were present in the blood. Similar observations have been made by other authorities, notably Chiarani and Bardanelli[2] in Rome.

Gowers[3] describes multiple neuritis in malarial subjects, attacking chiefly the lower extremities, where the muscles show true degenerative paralysis.

The neuralgias are frequently met with in practice. The usual forms are supraorbital and intercostal, but they may be located in the brachial plexus, musculo-spiral, crural, sciatic, or sensory nerves supplying the abdominal viscera. Pain in the abdominal nerves is very unusual, but Laveran[4] first pointed out that gastralgia sometimes occurs, referable presumably to the vagus nerve.

Strümpell[5] believes that both cardialgia and enteralgia may be produced by malaria.

According to Thayer[6] very severe attacks of abdominal pain may be associated with a pernicious paroxysm. There is usually profuse vomiting, and not infrequently hematemesis; intestinal symptoms may be quite absent.

Pathology.—Most writers are agreed that neuralgia is more often a sequence of malaria than a complication of the fever. Laveran states that in his observation, the pains almost always exist previous to the chills, and that when they occur in conjunction with malaria, are a result of the associated anemia. He considers that the paralyses are carried by thromboses or emboli in the vessels, made up of plasmodia.[7] Osler finds neuralgias more often from the malarial cachexia than during the fever.[8] The neuralgia, in Gowers' opinion, is not a distinct result of the malarial poison, but due to an anemic and depressed state of the nervous system induced by malaria.

Marchiafava and Bignami question the theory that neuralgia is set up by a localization of the parasites. They assert that sufferers from malaria are apt to have in addition to the fever frequent neuralgias of the supraorbital and other branches of the trigeminal, of the sciatic, crural, intercostal and other nerves, probably as a result of intoxication.

Mannaberg[9] states that no part of the nervous system is exempt from malarial neuralgia and that the pain may be coincident with the paroxysm or follow it.

The neuralgias of malaria may be classified in two groups, the *toxic* and the *post-infective*. The toxic neuralgias come on during the febrile attack, are associated with the presence of plasmodia in the blood and are due to an intoxication with the malarial poison. The post-infective cases are not associated with fever and the presence of parasites, and are the result of anemia and cachexia.

Diagnosis.—The recognition of malarial neuralgia appearing during the febrile period, is comparatively simple. The difficulty is in identifying the post-infective cases. According to Gowers the chief feature of the malarial neuralgia is the periodicity, in intervals between attacks ranging from one to four days. Occasionally there are slight symptoms of an ague fit, a trifling hot and cold stage.[10] Leube considers the most weighty symptoms in the diagnosis are enlargement of the spleen, and chills and fever along with the neuralgia.[11] Neuralgias, whether of the head or stomach, that are quotidian or tertian and yield to quinin, Manson[12] would classify as probably malarial.

As pointed out by Marchiafava and Bignami, however, periodicity of pain and relief by quinin are not sufficient to establish the diagnosis of malaria; the organisms must be seen in the blood. Other neuralgias than malarial may be periodic and may yield to large doses of quinin.

We would lay especial stress on the importance, not only of examining a fresh drop of blood for malaria, but of counting the white corpuscles in all obscure acute abdominal diseases, for not infrequently it furnishes the clue to the diagnosis. Salpinigitis and appendicitis, when at all acute, beginning peritonitis from any cause, and rupture of an extra-uterine pregnancy are usually accompanied by a decided leucocytosis, while malaria and typhoid fever and simple neuralgic pain are characterized by a normal or subnormal number of leucocytes.

The treatment of malarial neuralgia is first the destruction of any parasites in the system by large doses of quinin. When associated with febrile paroxysms the pain usually disappears in a short time unless the fever is of the estivo-autumnal type. The post-infective neuralgias are best combated by giving in addition to quinin some preparation of arsenic or iron to correct the anemia that is nearly always present.

SOME INCIDENTS IN THE EVOLUTION OF THE MODERN PHYSICIAN.*

WILLIAM ALFRED ELLISTON, M. D.
IPSWICH, ENGLAND.

The president commenced his address with notice of the associations of Ipswich and the deaths of Drs. Stewart and Paget, then passed to the subject of development of British medicine, which was the theme of his address. The early history of medicine in England is that of the Dark Ages; and down to the commencement of the sixteenth century, England had taken no part in the scientific advance of the century, and for almost one hundred years later no discovery of any importance was due to English research. The commencement of British medicine he dates from the return of Thomas Linacre to Oxford from the Italian universities, whence he came imbued with what was termed "new learning."

The great event in the sixteenth century, so far as medicine was concerned, was the success of Linacre in persuading the king to grant a charter to a small body of medical graduates, who were thenceforth called the Royal College of Physicians. He succeeded, it is said, principally through the great and powerful help of Cardinal Wolsey. The charter of the Royal College of Physicians was granted Sept. 23, 1518. It gave them the sole power to license to practice physic in London, or within seven miles radius, with other privileges, which were confirmed by a statute of Henry VIII, and extended to the whole of England. Linacre was the first president, and he held office to the end of his life.

---

* Abstract of Presidential Address, delivered at the Sixty-eighth Annual Meeting of the British Medical Association, held at Ipswich, August, 1900. [From advance galley-proofs kindly furnished by the Editor of the British Medical Journal.]

In 1540 the barbers and surgeons were united by act of parliament. They were incorporated as the "Maisters or Governors of the Mysterie and Commonalitie of Barbers and Surgeons of London." Thomas Vicary, sergeant surgeon to Henry VIII, who had been previously master of the Barbers' Company, was the first master of the combined companies. In 1543 the irregular practitioners of London were protected by act, and became one of the incorporations of that city, and both by royal charters and by acts of parliament exercised the power of granting license to practice medicine. In 1505 the Royal College of Surgeons of Edinburgh was founded, and in 1599 the Faculty of Physicians and Surgeons of Glasgow.

In the sixteenth century there were already established physicians, surgeons and apothecaries. The surgeons were associated in their Guild with the barbers, and the apothecaries with the grocers. While the physicians were men of education, cultured according to the education of the time, the surgeons and apothecaries were not a very highly-educated class.

GILBERT AND HARVEY.

It was at the commencement of the seventeenth century that the original research of two great English physicians, Gilbert and Harvey, completely altered the position of the country in scientific advance. Hitherto there had been no contribution of importance; from this time, however, a complete change came over the scene. William Gilbert—or Gilberd, as it is spelled upon his mural tablet—was born at Colchester in the same year that Vesalius was appointed professor of anatomy at Padua, in 1546. He was educated at Cambridge, and became a Fellow of St. John's in 1561. In 1573 he settled in London, and was subsequently appointed physician to Queen Elizabeth and president of the Royal College of Physicians. His leisure hours were given to chemistry and magnetism. In 1600 he published his *De Magnetc.* He established the magnetic nature of the earth, conjectured that terrestial magnetism and electricity were two allied emanations of a single force. He was the first to use the terms "electric force" and "electric attraction," and to point out that amber is not the only substance which when rubbed attracts light objects, and he described how to measure the excited electricity by means of an iron needle moving freely on a point. He described the properties of the magnet, and its attraction, and its direction in the relation of the poles of the earth. The work of William Harvey is well known. There are many evidences that his efforts were appreciated by his contemporaries, though the work which he published, and which has immortalized him, first saw light in Frankfort, Germany, chiefly because of the annual book-fair in that town.

It was about this time that a small body of students assembled at Oxford, in 1645, who was later, in 1662, to be known as the Royal Society. It was established as an association of men interested in the development of mathematical and physical science. It is the oldest scientific body in Great Britain, and one of the oldest in Europe. At one of the early meetings, fifty-two was fixed as the number of the society, persons of the rank of Baron, Fellows of the Royal College of Physicians, public professors of mathematics, physics, and natural philosophy of both universities being supernumeraries. In October, 1660, the king offered to be entered one of the society, and the next year the society was incorporated under the name of Royal Society, the charter of incorporation passing the Great Seal July 15, 1662. Soon after incorporation, the Royal Society published the papers by Malpighi, who by the microscope revealed the minute infinite particles of living bodies.

Somewhat earlier than this Boyle proved that a candle could not burn nor an animal breathe without what was afterward proved to be oxygen gas. These observations were said to have been attentively listened to at the early Oxford meetings of Wilkins and his friends by a young physician, John Mayow, who died at the early age of 34, but not before he had proved that air was made up of two portions—the one heavy, which supports flame and light, which he called fire air, and which was subsequently discovered to be oxygen; the other light, useless for living and breathing, that was the larger portion, which we now call nitrogen.

PRACTICAL MEDICINE.

Practical medicine in Great Britain was developing in this century; a pharmocopeia had been issued; cinchona bark was introduced; botanical gardens were established. The teachings of Lord Bacon, and subsequently John Locke, influenced the direction of thought, while the great learning and superb common sense of that great physician, Sydenham, gave effect to the general advance of this period.

In surgery, the growth was slow, principally through the general want of knowledge of anatomy acquired by dissection; but two Englishmen had distinguished themselves in this branch—Nathaniel Highmore and Thomas Wharton, the former discovering the cavity in the superior maxillary bone, still known by his name; and Thomas Wharton, who discovered the duct of the maxillary gland, which is still recognized as Wharton's duct. In medical politics, a warm contest arose between the physicians and apothecaries, the former accusing the apothecaries of usurping their province, the latter continuing and justifying the usurpation, until the matter was formally settled by the House of Lords in 1703, when it was decided that the duty of the apothecary not only consisted in compounding and dispensing, but also in directing and ordering the remedies employed in the treatment of disease.

The man who of all others at the early part of the eighteenth century gave an impetus to medical education was Boerhaave, who, at the University of Leyden attracted students from all parts. At this time there was practically no systematic medical training in the British Isles, but there were isolated attempts at special instruction. A refugee surgeon, Brussiere, setled in England in the time of Queen Anne, and for the first time gave lectures in anatomy in England. In 1711 Dr. Richard Mead lectured and continued his lectures for four years to the Barber Surgeons. In the same year Cheselden commenced a series of lectures which continued for twenty years. The first Munro opened a similar course at Edinburgh. John Rutherford settled in the same city in 1721. Speaking of him, his grandson, Sir Walter Scott, says, "he was one of those pupils of Boerhaave to whom the school of medicine in our northern metropolis owes its rise." Together with Sinclair, Purvis and Innes, he established a laboratory and taught the rudiments of chemistry and other branches of physics. In 1766 Rutherford was appointed lecturer in medicine, and until 1785 he delivered them in Latin. He founded clinical teaching in Edinburgh. The success was so great that the manager of the Royal Infirmary appointed a special ward to the exclusive use of Rutherford. This laid the foundation of that form of teaching, in which Edinburgh has held proud preeminence.

INCREASED STUDY OF ANATOMY.

Speaking of the history of medicine at this period, Lecky says, "a still more important fact in the history of medicine was the increased study of anatomy. The popular prejudice against dissection which had for centuries paralyzed and almost prevented this study, still ran so high in England that in spite of the number of capital punishments, it was only with great difficulty the civil power could accommodate surgeons with proper subjects, and all publicity was studiously avoided. With such a state of feeling, it is not surprising that the English Medical School in the beginning of the eighteenth century should have been far inferior to that which gathered round the chair of Boerhaave at Leyden."

The birth of chemistry, which may be dated from about the latter half of the eighteenth century, is the greatest scientific advance of the century, but practical medicine also was greatly advanced at this time. As early as 1703, Dr. Richard Mead communicated to the Royal Society an acount of Borrows' discovery of the acarus scabei, up to that time considered to be a constitutional disorder. It was then disbelieved in England, though recognized in Italy as early as 1787. This distinguished physician, of whom Dr. Johnson said, "Mead lived more in the broad sunshine of life than almost any man," was accustomed to drive six horses to Windsor, and he held consultations at coffee houses. Other physicians of whom Dr. Johnson spoke in terms of warm approbation were the elder Heberden, and of his great friend, Dr. Robert James, who did not think it beneath his dignity to take out letters patent for his famous powder in 1746. Dr. Lettsom, one of the most successful of the long roll of Quaker physicians, lived well into the nineteenth century.

Dr. James Lind was one of the thinkers of the century, and deserves to be remembered. He was a surgeon in the navy in 1739, and took his M. D. in Edinburgh in 1742. He published a treatise on scurvy in 1754. More men died of scurvy in the naval wars preceding its publication than were killed in all the engagements of the French and Spanish fleets. The book attracted great attention at home and abroad. He suggested the use of fruit and vegetables and lemon juice. It was not, however, until some forty years later that an *order was issued by the admiralty for its use. In 1761 he discovered* that the steam of salt water [illegible] fresh, and demonstration of the [illegible] society.

The discovery of vaccination is perhaps the most striking landmark of this time. It was quite at the end of the century that Dr. Matthew Baillie, whose labors extended through the first quarter of this century, published his "Morbid Anatomy" of some of the most important parts of the human body. It was the first book on the subject in English, and excelled any of the previous Latin treatises in lucidity. It was the first book in which morbid anatomy was treated by itself. In this work he described ulcers of the stomach and of typhoid. He defined the change of the liver in cirrhosis. He described and differentiated various abdominal cysts and other important pathologic observations. He was a distinguished member of a distinguished family, his mother being a sister of William and John Hunter. He was appointed physician to St. George's Hospital in 1787.

Of the development of practical surgery, it was carried on on less distinct lines in Great Britain than elsewhere, and particularly in Paris, where the Academy of Surgery in 1731 set up a very high standary from the first. We note the brilliant ability of many individual surgeons—such as Cheselden; John Freke, of Bartholomew's, first to treat empyema by incision; Dale Ingram, the first surgeon to treat abdominal wounds on modern lines; the eminence and ability of Percival Pott, who published his works after a severe accident when 43 years of age, and the transcendent genius of his pupil, John Hunter, who was almost the same age before he published his first book; and the sound and scientific work of Cline. All these, as well as many provisional surgeons—such as White, of Manchester; Goch, of Norwich; Hey, of Leeds, and Parks, of Liverpool—helped to establish surgery as a scientific branch of medicine.

In 1745 the Barber Surgeons were dissolved and were corporated as distinct societies. It seems impossible at the present time that they should have lasted so long. Nothing definite occurred to the Apothecaries after the great decision in their favor by the House of Lords, and but little has been written of them in the eighteenth century, save the allusion to Robert Levett in Boswell's "Life of Johnson." The scanty means of education in London, and the absence of medical societies there during this period are also noted. Until the last quarter of a century, there was no means of obtaining a medical education in London. Surgeons and apothecaries were supposed to be able to pick up a sufficient smattering of their work by attending a hospital for a few months, and physicians were educated elsewhere. Some half a dozen took a degree at Oxford or Cambridge, and these alone could become Fellows of the Royal College of Physicians; others, a much larger number, went to Edinburgh and the Scotch universities, Dublin or abroad.

MEDICAL SOCIETIES.

The education of Edinburgh was far ahead of London; medical societies and periodicals flourished there before in the south. There were medical societies in Edinburgh as far back as 1720. In London, there were societies of 1753 and 1764; they were both small societies and disappeared after Hunter's death. The only medical society in England, outside London, was the Medical Society of Colchester, founded in 1774. The absence of societies was much felt by earnest practitioners desirous of progress. Dr. Edward Jenner belonged to a medical society which met at the Fleece Inn, Rodburgh. Papers were read on medical subjects, and the members afterward dined together. At these meetings Jenner read papers on various subjects. He also belonged to another society, which met at the Ship Inn, Alveston.

In London, in 1783, there were five lecturers in anatomy, three lecturers on surgery, and three lecturers on the practice of medicine.

The great medical schools of London and of the provinces have almost all been established since this period, and, indeed, most of them in the present century. Learned societies in medicine from this time became established, and now they exist in all parts of the kingdom.

The eighteenth century closed with a great advance in general science, especially in chemistry and electricity, and some of the leading discoveries of this time are briefly mentioned.

MEDICAL LEGISLATION.

The important legislation of the nineteenth century was the Apothecaries Act of 1815. Previous to this act the education of the medical practitioners of England and Wales was entirely optional on their part, and although many of them possessed degrees or licenses of the universities or colleges, the greater number possessed no such qualification, and many of them were wholly illiterate or uneducated. About the year 1850 a preliminary examination in arts was instituted as a necessary and independent requirement before proceeding to the medical curriculum. In 1858 the Medical Act became law, and by this act the L. S. A. of London was permitted to practice through Scotland or Ireland. The Apothecaries Amended Act passed into law in 1872. Women were admitted to practice in 1876. In 1878 the pharmaceutical chemists were licensed by act.

It is worthy of observation that the state had hitherto not interfered to prescribe the subject-matter, or the minimum standard of medical examination, although there has been at least one attempt of the government of the day to establish a uniform minimum. Under the beneficent legislation of the century, and particularly by the establishment of the General Medical Council, jealousies between the different branches of the profession have mainly disappeared, it is difficult now to realize that at the commencement of the present century it was far otherwise.

The use of wise legislative enactments in the social influence and status of the profession soon became apparent, but its full effects were not evident until many years had elapsed. It is quite within memory that the only qualification recorded in many instances in the annual "Medical Directory" was "in practice prior to 1815." It is not a little singular that the Apothecaries Act has gradually extinguished the apothecary, as then understood. With the better education required, and the institution of examinations, a different class of students were attracted to medicine, and they were rarely satisfied with the apothecary's license, but sought further a surgeon's diploma.

The Anatomy Act of 1842, by growing facilities in the practical studies of anatomy, was one of the most important dates in the medical education instruction of the time. The growth of the medical press commenced with the efforts of W. Sharman in 1767, who in 1810 commenced to edit a periodical which was still in existence in 1815. The foundation of the *Lancet* in 1823 by Thomas Wakley is a landmark in British medicine. Its early struggles have been fully given in its pages of late years, and need not be related here. Among the physicians and surgeons of the present are many that come down almost to our own day, and therefore are more or less familiar.

The address collects some interesting facts, among which are the following:

In 1837 Gerhard, a young American physician, clearly laid down the difference of the two diseases of typhus and typhoid fever. After much doubt and discussion, the question was finally settled in England by Sir W. Jenner in 1849-50.

The credit of recognizing the connection between the acceleration and violent actions of the heart and the enlargement of the thyroid gland, two of the great cardinal symptoms of exophthalmic goiter, undoubtedly belongs to the great Dublin physician, Graves, who, in 1835, pointed out, in a published lecture, that the disturbance of the heart's action is not necessarily associated with organic disease of the heart. Five years later, a German physician, Basedow, published a more complete and elaborate account of the clinical features.

Hughes Bennett first described leucocythemia in 1845. A few weeks afterward Virchow published a case which had been independently observed by him previous to the publication of Bennett's first communication on the subject, and pointed out that the white corpuscles found in the blood were not pure cells, and termed the disease leukemia. A violent controversy sprang up between these two celebrated men and other supporters. Of this Byrom Bramwell says "that while Bennett was the first to observe and publish a detailed case of the pathologic appearances and blood changes, Virchow was the first to give an intelligent explanation of the peculiar *alteration of the blood, which is the essential characteristic of* the disease."

It is not, perhaps, so generally known as it deserves to be, that William Jeaffreson, of Framlingham, in the county of Suffolk, an East Anglian surgeon, was the first surgeon in England to perform the modern operation of oviariotomy by a small central incision. The circumstances, as recorded in the Transactions of the Provincial Medical Association of 1837, are as follows: "Mr. Jeaffreson in 1833 lost a patient suffering from an abdominal tumor. She died from tuberculous disease of the lungs, and, obtaining the consent of her friends, he made a post-mortem examination, which satisfied him that the tumor could have been removed, and but for the disease of her lungs, her life might have been spared."

In November of the same year, Jeaffreson and his friend, King, attended together a lady in her confinement who had a small tumor. They subsequently advised an operation, and in May, 1836, a central incision was made, about 1½ inch, the cyst tapped, withdrawn, the pedicle secured by ligature, and the ends cut off short. The wound was adjusted by two sutures, and napkins wrung out in the coldest water were constantly applied to the wound. Sulphate of magnesia was administered every four hours, and all went well until the tenth day, when he was called to his patient at 3 a. m., to find her pulseless with incessant vomiting and hiccough, with griping pains in her body. A stimulating enema, with gr. 2 of opium, gave her speedy relief, and she recovered.

His friend and neighbor, King, at Saxmundham, Suffolk, about ten miles away, operated a few weeks later, with complete success, his incision being somewhat longer—about 3 inches. Two years subsequently a third East Anglian surgeon, Crisp, of Harleston, who lived about twenty miles from Jeaffreson, was also successful, with an incision of 2 inches. These three cases, which were performed by three surgeons in general practice in England, are the more remarkable when we consider that no operation of the kind was attempted in London until four years later, and no ovariotomy was performed in a London hospital until ten years after Jeaffreson's case.

The two great discoveries of the nineteenth century, antiseptics and anesthetics, are briefly alluded to, but no mention is made of the American part taken in the latter discovery. Public health and state medicine is entirely modern. The science of modern military hygiene is credited to Parkes, who was also a great factor in, if not the founder of, the science of modern hygiene. Two centuries ago the mortality of London is said to have been 80 per 1000. At the present time it is only 20. All the special departments which concern the surroundings of man, personal health, food, drink, clothing, hours of labor, management of infancy, prevention of disease, hygiene of the sick chamber, and disposition of the dead, have been the subject of legislation during the present century.

THE SURGEON OF THE NINETEENTH CENTURY.*

FREDERICK TREVES, F. R. C. S.

LONDON, ENGLAND.

The surgeon of one hundred years ago was but a sorry element in social life. In the great towns and cities there were a few practitioners of surgery who were eminent by reason of their scientific work and successful practice. London was then the center of surgical activity, and the prominent exponents of the art were John Abernethy, Henry Cline, Sir William Blizard, Sir Everard Home, Sir Astley Cooper, William Lawrence and Charles Aston Key. The great John Hunter had died in 1793, having accomplished a work which marks an epoch in British surgery. In the provinces the most conspicuous surgeons were Edward Alanson, of Liverpool, and William Hey, of Leeds, while in Edinburgh the position of the leading operator was held for many years by John Bell. A little later in the century we find among the names of prominent men in England those of Sir Charles Bell, Sir Benjamin Brodie, and the ingenious and learned Benjamin Travers.

At the beginning of the century surgery on the Continent was represented by such men as Sabatier, Deschamps, Boyer, and Larrey in France, Scarpa in Italy, Langenbeck, Chelius, and Diffenbach in Germany, and Warren and Physick in America.

Smollett, who was himself in turn an apprentice, an assistant, a surgeon's mate, a practitioner and a graduate in medicine, has furnished a discouraging account of the surgeon, practitioner or leech of his time. He was ignorant, illiterate, sordid, a mere retailer of physic, not above the allurements of money-grabbing, and not without suspicion of dishonest practices, and of a leaning toward the bottle. Smollett's description could not have been true of all his brethren, and there is no doubt he wrote with the bitterness of an unfortunate experience. Launcelot Crab undoubtedly represented a type not yet extinct when the century began, and he must be taken as a forerunner of the cultured and esteemed general practitioner of the present day.

The Surgeon as an Adviser.—One cannot fail to be impressed by the paramount influence which exact knowledge—or the want of exact knowledge—has had upon the attitude of the medical profession. There is no science outside of our own in which there has been, during the stages of development, such an extreme disproportion between the amount of knowledge professed and the amount proved ultimately to be exact and sound. The reason for all this lies more with the sick man than with the man of medicine. The sick man requires absolute and exact knowledge from his doctor. He will accept neither possibilities, doubts nor confessions of ignorance. It is no wonder that in the past the physician made good by fiction what he lacked in fact. The demands of the patient have been hopelessly beyond any power of supply, and the deficiency has been furnished by the products of invention. A good deal of the pretense and humbug with which medical practice has been associated in the past has been forced upon the practitioner by the demands of unreasoning people. With such people the surgeon, in the early part of the century, had more largely to deal than he has to do at the present day, and yet his stock of knowledge could seldom meet the demands even of the reasonable. A false attitude toward his patient was unconsciously forced upon him, and the folly of his pretense to an unattainable learning was apparent to all but the simplest. As an adviser, therefore, he spoke not as one having authority. The surgeon of the present day, as an adviser, is in a position which could hardly have been imagined by his forbears of one hundred years ago. He has to deal with a more enlightened public, with patients whose education enables them to appreciate the nature of scientific problems, and with whom it is possible to discuss difficulties, and to own to lapses of information. The additions made to surgical lore have been so substantial that, in many departments surgery is an exact science. There is indeed no longer need to call upon invention to supply such gaps as still indicate the unknown. An intelligent patient is satisfied with the assurance that practically nothing at present is known of the nature and causes of cancer. We have perhaps not quite shaken off the poor vestments of mummery with which ignorance was clad, nor rid ourselves of forms of speech which still pass current for sense. We speak assuredly of the "constitution" and of "states of the system" and of the "supporting of the system." We sanction such terms as "poverty of blood," "diminished vitality" and "sympathetic inflammation." We profess to believe in "tonics," in medicines the swallowing of which will give strength, in "galactagogues," in "alteratives," in "astringents," and in "cooling physic." We profess moreover to "strengthen the lungs" and give "tone to the stomach." The modern surgeon can well afford to dispense with all this empty verbiage, since he can base his opinion upon facts, and can express it in plain words, free from embellishments.

The Surgeon as a Man of Learning.—We can only view with amazement the scantiness of learning and the poverty of equipment of the surgeon at the commencement of the century. He knew little more of inflammation than that it was represented by swelling, heat, redness and pain. He had no glimmer of the possibilities of asepsis. He had no anesthetic, no hypodermic syringe, no clinical thermometer, and no practical means of investigation in clinical chemistry. Bacteriology did not exist, and the treatment of disease by prepared serums would have appeared to him as a wild therapeutic dream. Although vaccination had been introduced in the last year of the eighteenth century, the magnitude and nature of the principle it involved had not been appreciated.

The microscope as an aid to diagnosis played no part in the equipment of the surgeon. He had neither laryngoscope nor ophthalmoscope, and his acquaintance with otology, skin affections and the diseases of women was at the best rudimentary and indistinct. He had only rude medieval orthopedic appliances, and knew nothing of the lithotrite nor of the array of instruments which are now in daily use in connection with surgery. It would seem indeed that there was little for him to do but to open abscesses and sow the seeds of chronic septicemia, to excise tumors, of the structure of which he talked much and knew little, to amputate limbs for diseases he could not mend, and to draw blood whenever doubt existed as to what was best to be done. In 1800 a man could practice as a doctor without passing an examination of any kind. Indeed, one itinerant practitioner is reported to have assumed the title of assistant surgeon on the ground that he had served an apprenticeship to the crutch-maker of a hospital. The examination for the diploma of the Royal College of Surgeons was oral only. There was no examination of patients, and no dissection of the subject. Candidates were required to produce evidences of apprenticeship, of attendance upon anatomical and chirurgical lectures, of having performed dissections, and of having attended the practice of a recognized hospital for a period of six months. In 1813 the period of compulsory attendance at a hospital was raised to one year. The standard of knowledge, however, does not appear to have risen in corresponding proportion, for in 1822 the then president, Sir William Blizard, felt called upon to address the Court of Examiners on certain "tokens of remissness in teachers, and of inattention in students," which had been forced upon his notice. He regrets the remarkable deficiency of candidates in anatomical and physiological information, and concludes by deploring that there is a "corresponding darkness of mind relating to the symptoms, seat, causes, and rational treatment of diseases and injuries." At the commencement of the century there was, indeed, no systematized medical education. The training of the surgeon was paltry, casual and inefficient. His preliminary education was meager. It was necessary that he should be able to read and write and pretend to some smattering of Latin. So far as hospital practice was concerned, his attitude as a learner was well expressed by the phrase, "He walked the hospital." The institutions which he thus attended for a period of six months were in a state of squalor as regards administration, sanitary arrangements and nursing, and well deserved the abuse which was lavished upon them.

---

* Abstract of the Address in Surgery, delivered at the Sixty-eighth Annual Meeting of the British Medical Association, held at Ipswich, August, 1900. [From advance galley-proofs kindly furnished by the Editor of the British Medical Journal.]

The Surgeon as an Operator.—During the nineteenth century the surgeon, as an operator, passed through a rapid metamorphosis, and has now reached at least the level of the unexpected. Time has shown that even in 1800 there was a technic in operating which was as little like the technic of to-day as are the slashes of a cutlass when compared with the studied movements of a foil. It may have been surmised that twenty centuries would have exhausted the methods by which a limb could be cut off. Yet in 1800 modes of amputation were in vogue which are now regarded as uncouth, and there was not in use a ready and efficient means of checking bleeding.

The operator of olden times certainly possessed many qualities which are now falling into abeyance, his success depending largely on his daring, on the alertness of his eye, the steadiness of his nerve and the rapidity of his movements. He stepped into the arena of the operating theater as a matador strides into the ring. Around him was a gaping audience, and before him a conscious victim, quivering, terror-stricken and palsied with expectation. His knife was thrust through living flesh and acutely-feeling tissues, and the sole kindness of his mission was to be quick. There is less need for such qualities now. The dramatic element in surgery has gone with the men who unconsciously fostered it. The operating theater has changed from a shambles to a chamber of sleep. The surgeon's hand can move with leisurely precision, and theatrical passes of the knife are favored only by those who have not yet learned that mere brilliancy is no measure of success. It is little wonder if the older surgeon became rough and stern, if his sense of feeling became dulled, and if the sympathetic side of his nature suffered some suppression. Indeed, contemporary accounts are apt to represent the operator of preanesthetic times as rough almost to brutality, and as coarse both in his conduct and in his utterances. His language, it would appear, savored of the cockpit, and the hasty flourishing of his knife led occasionally to unintended mutilations.

An Improved Knowledge of Anatomy.—Among the surgeons of the early part of the century there were many competent anatomists, and not a few who could lay claim to be deeply versed in that science. Among the latter were such men as Astley Cooper and William Lawrence. Still, in the education of the average surgeon the study of anatomy did not play a prominent part. Anatomy was largely taught by means of public demonstrations, the teacher dissecting while the student looked on. The knowledge acquired was scant and superficial, and had little practical basis. The science of anatomy was well advanced at the commencement of the century, but it was not taught to the common student. "Quain's Anatomy," first published in 1828, was a single small volume of 700 pages, without illustrations. The facilities for acquiring a practical knowledge of anatomy were not only few, but were hampered by many sordid difficulties. Anatomical schools were regarded with disfavor and unconcealed suspicion by the public, and were surrounded by a ghoulish romance in which rifled graves and unseemly dealings with the hangman played a pungent part. Indeed, the teacher in an anatomical school found himself involved in a squalid and disreputable traffic. Among the many qualifications needed for success in operating, a practical knowledge of anatomy, as acquired by repeated dissection, is conspicuous. Such knowledge as the surgeon needs must be learned from the patient use of the scalpel and forceps. The dissecting room is the surgeon's nursery. The older surgeon often lacked confidence in operating, failed in initiative, clung only to formulated methods, and a departure from accepted lines was attended with fear and hesitancy. Ignorance encouraged in the rash heroic passages of the knife, and in the timid an over-cautious and dangerous fumbling. In preantiseptic days much ill attended the nervous fingers creeping clumsily into the unknown.

A Readier Method of Arresting Hemorrhage.—At the commencement of the century the means employed for the control of bleeding were numerous, and included the ligature, the suture, styptics of many kinds, and actual cautery. In applying the ligature the vessel was picked up by forceps and tied as at the present day. The instruments used were those of Diffenbach, Assilini and Liston. The bleeding from the vessel was not necessarily controlled by the forceps when in position. The general rule in amputation was to apply a tourniquet and to ligature the individual arteries after the limb had been removed. In the excision of tumors each vessel was secured as it was divided. When it is remembered that operations were carried out without anesthetics, it will be understood that the older surgeon had an absolute terror of bleeding, and was driven to undesirable shifts to avoid the need of facing it. Hemorrhage was expected, and a liberal loss of blood was considered a necessary adjunct to every major operation. Tourniquets were employed freely and with considerable harshness. Raw surfaces were bathed with styptic solutions which were often destructive in their action, or at least opposed to primary healing. The actual cautery to sear the bleeding area was in some request; and every well-equipped operating-theater kept its stove and cautery irons in constant readiness. The écraseur was of later date. Its invention was due to Chassaignac, and it was freely used in England until quite recent times. It was employed for the removal of growths of different kinds, but its most baneful employment was as a means for excising the tongue. It is scarcely to be believed that within the period of the introduction of anesthetics the tongue has been torn out of the mouth by means of a loop of hemp or wire which strangled it at its root. The *écraseur* will remain in the archives of surgery as the insignium of the incompetent and the timorous, and will stand out as a blot in an otherwise bright period of progress and enlightment. The shadow of this medieval instrument has been slow to fade, and like the ovarian clamp and the *serre nœud*, it clung about the confines of reasonable surgery, and hindered the development of the operations of ovariotomy and excision of the uterus.

At the present day the surgeon has little dread of hemorrhage. He makes larger use of the precautionary ligature of vessels; he is operating on an anesthetized patient, and can proceed with slowness and deliberation, and the treatment of hemorrhage has been simplified, if not indeed rendered complete, by the introduction of the pressure-forceps, the most valuable addition which has ever been made to the surgeon's appliances.

The Employment of Anesthetics.—The changes that the discovery of anesthetics has wrought in the personality of the surgeon, his bearing, methods, and capabilities are as wondrous as the discovery itself. He is undisturbed by the harass of alarms, and the misery of giving pain. Time now counts for little, and success is no longer to be measured by the beatings of a watch. The mask of the anesthetist has blotted out the anguished face of the patient, and the horror of a vivisection on a fellow man has passed away. Thus the surgeon has gained dignity, calmness, confidence, and, not least of all, the gentle hand. Anesthetics have, moreover, greatly extended the domain of surgery, by rendering possible operations which before could have been only dreamed about. The introduction of anesthetics has not only developed surgery, but it has engendered surgeons. It has opened up the craft to the many, for in the preanesthetic days the qualities required for success in operating were to be expected only in the few.

The Introduction of Antiseptic Measures.—When the century was young the touch of the operator was the touch of a tainted hand; the balm he poured into the wound was poisoned, and he himself undid the good his science strained to effect. It is sad to think that behind the earnest man with the ready knife there stood a shadow which rendered hopeless his kindliest effort, and which only too often proved to be the veritable shadow of death. The change has been great, and its greatness lies in its littleness, for it is bound up with no more than this: that the surgeon has learned to be clean, and has become aware of the potency of little things. The demands of the antiseptic treatment have made him minutely careful, distrustful of any aid that he cannot control, and suspicious of any semblance of error.

The Surgeon in the Future.—The changes which have swept over the world of surgery have extended the possibilities of the art, and have, at the same time, added a host to the ranks of those who practice it. Thirty years ago the roll of such as could claim to be accomplished operators was very small. The greater deeds of surgery were limited to cities and the larger towns. The general practitioner seldom took up the scalpel except in minor necessities. Even in London the list of consulting surgeons was meager. In the hospitals of the metropolis the number of operations performed in the year would be less than is now the quotum for a month. At the close of the century, however, the disposition of affairs is wholly altered. Where there was one surgeon there are now ten, and the work of the operator has extended. The more ambitious performances of surgery are no longer restricted to great centers, but are carried out in the little town, in the cottage hospital, and even in the cottage itself. The general practitioner is laying claim to operate upon his own patients, and is carrying out his intention in no hesitating manner. The days of the great operator are rapidly passing away. Indeed, the practice of pure surgery is now becoming common to the many. The man who excels conspicuously as an operator will always attain such eminence as his ability deserves, but the exclusiveness of the practice of operative surgery is quietly vanishing. In every great change there must—at first, at least—be some undesirable developments, and the wider distribution of the practice of operative surgery may lead to the occasional performance of major operations by men who are not justified in undertaking them. There is also some evidence that the reaction in the matter of operative surgery is to some degree extreme, and that we are in danger of passing from the policy of doing too little to the policy of doing too much. Operations were too few in the past, but they may be too frequent in the present.

So many have been the artificial aids to clinical investigation which recent science has introduced that it comes to be a question whether the natural acumen of the surgeon will not deteriorate in proportion as he fails to encourage that particular learning which clings to the finger tips of all great diagnosticians. The loss is to be deplored, for if there be one point of excellence which stands before all in the qualifications of the perfect surgeon, it is bound up in that refined sensibility, that critical perception, that inestimable cunning which lies in the surgeon's touch. A considerable amount of skill is demanded in the examination of complex fractures, of lesions of deep-seated bones, and of injuries about joints. What was to be learned of these troubles had to be acquired by a tedious manipulation demanding considerable refinement. The surgeon now submits the inquiry to a demonstrator of the Roentgen rays. The skiagraph, although its value is much exaggerated, embodies a substantial gain, but it is to be discounted by the loss of the great element in education which it is slowly replacing.

An obscure tumor presents itself; no longer is the surgeon compelled to trust to the acuteness of his inquiry, and his patient review of all the physical details of the mass. For what his ready fingers may have learned can be substituted the findings of the exploratory incision, the trochar and the aspirator. Here once more an advantage is minimized by a loss.

An abdominal swelling is brought under notice. Its features are obscure, but much of the uncertainty of outline can be dissipated by a cultured hand, which, with infinite patience and repetition, has learned to construct a reality out of a shadow. The problem can now be solved at once by an exploratory laparotomy. By this operation a great advantage is gained, but an opportunity to add to one of the most refined forms of learning is lost. The value of the exploratory incision is beyond question, but among the signs of the times it is impossible not to notice a tendency to resort too readily to this means of solution. A suspicious ulcer presents itself for diagnosis. In such case is it well to devote time to a precise and tedious inspection of its edges, and to a careful tactile examination of its base, and to check what is discovered by results laboriously gained from like inquiries? Is it not simpler to take a scraping of the affected surface and to submit it to a microscopist?

Finally, there are cases which present symptoms hard to interpret at any superficial inquiry. Is it worth while in such to undertake an exhaustive critical research, and to submit the whole to a trained judgment? The quest would no doubt develop habits of observation and powers of weighing evidence; but the process is slow, and an inquiry carried out in a bacterial laboratory will clear up all doubts.

Those, therefore, who are concerned with the education of the surgeon of the future would do well to still cherish this ancient power, and to foster a memory of the fact that surgery is, in its very essence, a handicraft, and that, in all that he does the surgeon's great endeavor should be to make his own hands self-sufficing.

It is sad to think that this hardly acquired faculty dies with the possessor of it, and never was this more vividly presented than it has been by the loss which surgery has sustained in the death of Sir James Paget. One can picture the great surgeon composed in his last sleep, and can see the once busy fingers lying lifeless on the white sheet, and then comes the wonder at the wealth of learning, at the exquisite cunning, at the refined sense which lay dead in the hand.

An individual loss does not however, hinder the general tide of progress. Advance in such a work as ours depends upon the uneventful work of the whole body, and is only accentuated by the achievements of the prominent few. The movement is the movement of a multitude in which individuality is, at a distance of time, little to be distinguished, and in which personal eminence contributes a smaller factor than the present is ready to acknowledge. Those who stand forth as the leaders of the advance are merely the elect of the common body, and the representatives of a wide intellectual franchise. Even he who startles the world as a discoverer has often done little more than give expression to what was already nascent in the multitude. So as one great surgeon after another drops out of the ranks, his place is rapidly and imperceptibly filled, and the advancing line moves on with still the same solid and unbroken front.

The continuity of progress is undisturbed by the uncertainties of human life, and, as one writer has well expressed it—

"No work begun shall ever pause for death."

Therapeutics.

Cholera Infantum.

Lesarge (*Montpellier Méd.*) advises:

1. Strict diet, not more than 200 grains of milk, or even nothing but cracked ice to allay thirst. Ingestion of milk aggravates the digestive troubles. When gastrointestinal symptoms have almost disappeared, feeding is to be begun gradually, the milk at first being iced.

2. Give 20 to 30 grams of cognac or rum per day, in four to eight doses, either pure with ice, or in black coffee, one teaspoonful of the alcoholic liquor to a tablespoonful of coffee.

3. Hot baths (98 to 100 F.) lasting ten minutes, morning and evening. Add a little mustard during the last four minutes. Gentle friction with warm cloths or cotton wool. Hot-water bottle.

4. At first, while there is fever and no sign of collapse, give .01 gm. calomel in a teaspoonful of water every two hours for twelve hours; or the following:

℞.	Tinct. op. camphor. (paregoric)	gtt. x
	Acidi lact.	ʒss
	Syr. simpl.	ʒiv
	Aquæ	℥iii
	Ess. menth. pip.	gtt. ii

M. Sig. One teaspoonful with ice every half hour.

Or the following mixture of HCl and lactic acid:

℞.	HCl. or acidi lact.	ʒss
	Aquæ	℥iiss
	Syrupi	℥iii

During the period of algidity, .2 to .25 gm. caffein in water, given in two or four doses, has a marked diuretic effect and heightens the arterial pressure.—*Pediatrics.*

Vesicular Eczema of Scrotum.

According to Wittzack, it is not advisable to use a powder, since, when mixed with the secretion from the affected surface, it cakes and falls off. The application of compresses wet with an astringent solution is recommended, as for instance:

℞.	Aluminii acetat.	ʒv
	Liq. plumbi subacetat.	℥ss-℥iiss
	Aquæ	℥iii

M. External use.

If the epithelium is gone it is best to employ a mixture of one or two parts of white precipitate ointment with Lassar paste. It will often be found helpful to cauterize by means of a solution—10 to 50 per cent.—of caustic potash applied on a cotton tampon; the caustic is then washed off and the part covered by Lassar paste. Or nitrate of silver—10 to 20 per cent. solution—may be chosen.—*Med. News.*

Boric Acid Intoxication.

R. B. Wild, after citing a number of cases, including some of his own, distinguishes two forms of intoxication from boric acid—one in which a large quantity of the drug is rapidly absorbed from the alimentary canal, from a serous or other cavity, or from an extensive raw surface; in these cases vomiting and diarrhea, general depression, and partial paralysis of the nervous and muscular systems occur, and may cause death. A rash is noted in many instances, especially when the patient recovered or lived some days after the absorption of the drug. The other class of cases results from the administration of boric acid or borax in comparatively small doses for long periods, and the symptoms appear at a variable time after the commencement of the drug. In some of these cases it is mentioned that the kidneys were diseased, and the author gives as a possible reason for the immunity to the injurious effects of boric acid its very rapid elimination by healthy kidneys.

Furthermore, it is possible that cases of intoxication occur more frequently than is at present recognized. Boric acid may unwittingly be taken in food and cause a toxic eruption which may be mistaken for eczema, psoriasis, or exfoliative dermatitis.

It may be noted that a 1/500 solution corresponds to 175 gr. per pint of the acid, a very large dose for an infant on milk diet and one likely in some cases to produce disturbance of the alimentary canal. It should also be ascertained that the milk ordered in cases of kidney disease is free from excess of boric acid or borax. The use of boric acid or the borates in surgery and their internal administration ought to be carefully guarded in patients with diseased kidneys, and immediately discontinued on the appearance of dermatitis or other toxic symptoms. In suspected cases examination of the urine may afford valuable evidence of the presence of the drug.—*The Lancet.*

Compound Tincture of Benzoin in Enteric Fever.

Dr. James C. Potter, of Spennymoor, Durham, writes the *British Medical* as follows:

Lately I have had under my care several cases of enteric fever with excessive diarrhea. I have in these cases tried a mixture of compound tincture of benzoin and water, with marked success. I start by giving a dose of 5 minims of the tincture every two hours, and if the diarrhea does not decrease in twelve hours I then double the dose. In all the cases, after twenty-four hours' administration, I have found marked benefit; the diarrhea decreases, the stools are not so offensive, the temperature is decidedly lowered, and the patient feels very much more comfortable. I attribute the success in these cases to:

1. The internal antiseptic property of the drug.
2. The mixture forming a protecting coat to the inflamed bowel.
3. The antipyretic action of the drug.

Malnutrition in Infants.

The combination of a yolk of egg and olive or cottonseed oil made into an emulsion is found very useful in cases of rickets or chronic malnutrition in infants. The emulsion may be made as follows:

℞.	Ol. olivæ	ʒiii
	Glycerini	ʒss
	Yolk of two eggs	

M.

Make an emulsion and add one-half minim of creosote to each dram. Occasionally it is better to use a smaller amount of creosote when the agent is not well borne by the stomach. A full teaspoonful of the emulsion is given three times a day after feeding. The preparation seems to be readily tolerated, even when the stomach is irritable.—*The Practitioner.*

Dyspepsia Accompanied by Acne.

Dr. Mitour (*Révue de Thérap.*) recommends for dyspepsia accompanied by acne, light meals frequently repeated. The food should be well masticated and of a kind easily digested. Bread, spiced meats, preserved fish, pastry, butter, and fatty foods should be avoided. Alcohol and milk are also injurious. Water is the best drink and should be taken sparingly with meals. Medical treatment has three objects:

1. To stimulate the secretion of hydrochloric acid, there should be given before meals sodium bicarbonate, with sodium and potassium sulphate in small doses, or ipecac, or condurango.
2. To stimulate muscular action of the stomach the tincture of nux vomica may be given after meals.
3. To prevent fermentation, naphthol, benzol, betanaphthol, or bismuth salicylate is indicated. Sodium sulphate and calomel are recommended for constipation with intestinal inflammation. Hydropathy with abdominal massage, gastric lavage and electricity have given excellent results in certain cases.—*Med. Record.*

Arsenic and Belladonna in Chorea.

In a recent issue of the London *Lancet,* Overend concludes an article on this topic in the following summary:

1. Belladonna appears to be most beneficent in recent cases, but its influence is sometimes very marked in severe forms.
2. In obviously rheumatic cases arsenic in large doses may be given a trial or may be combined with belladonna from the first. Belladonna may act by diminishing the excitability of the nerve-centers or by imparting an improved tone to their vascular supply.
3. In the wards of a hospital it is perfectly justifiable to give to a child as much as 30 minims or more of the tincture of belladonna every four hours for ten days or even longer. Certain precautions are necessary. The patient should be kept in bed and the urine should be daily measured. Small doses of potassium acetate may be added if it becomes much diminished or if the eyelids show any puffiness. In one child nocturnal incontinence occurred, and the dose was lessened. The occurrence of the popular erythema, which leaves raised circular lumps for a time, does not necessitate any diminution of the dose. Dryness of the throat and swelling of the parotid, should they occur, are only temporary. The influence of the belladonna makes itself felt after about four days. Should no visible improvement occur before the tenth day it would be useless to continue with it. But in eighty-seven cases treated, belladonna was of benefit, and is certainly worthy of further trial. As soon as the movement becomes trivial or occurs only during exertion, it is better to omit the belladonna, to commence massage of the affected muscles, and administering cod-liver oil and syrup of phosphate of iron or other tonics. The arsenic may be continued for a week or longer.

Bad Breath.

℞.	Acidi salicylici	
	Sacchari	
	Sodii bicarb., āā	gr. xv
	Alcoholi	℥i
	Ess. pip. menth	gtt. x

M. Sig. ʒi in wineglassful hot water and gargle once or twice daily.

℞.	Potassii permang	gr. vi
	Aquæ	ʒvi

M. Sig. Gargle frequently. (Also good for swelling of axillæ, fetor of the sweat of the feet, etc.) —*Palmer.*

Sedative Enemata in Painful Affections of Posterior Urethra.

In cases of very painful urethro-cystitis with tenesmus and spasm of the internal sphincter, as well as in cases of acute prostatitis and epididymitis. Dr. P. Scharff, of Stettin (*Med. Week.*), has found that small morphin or belladonna enemata exert a more rapid and more powerful action than the ordinary sedative suppositories in common use.

For this purpose he prescribes one of the following mixtures:

℞.	Morphinæ hydrochloratis		3
	Atropinæ sulphatis		01
	Aquæ dest	100	

M. For external use.

Five grams (one teaspoonful) is injected into the rectum and the analgesic action of the enema begins to manifest itself within from two to fifteen minutes. In cases in which the pain is associated with fever, Dr. Scharff injects into the rectum as often as three times a day, if necessary, 5 grams of the following solution:

℞.	Cocainæ hydrochloratis	1
	Antipyrini	
	Sodii salicylatis, āā	10
	Aquæ dest	200

M. For external use.—*Am. Medico-Surgical Bulletin.*

Syphilis and Paresis.

An abstract in the *Quarterly Journal of Inebriety* gives the following significant passage from a paper by Dr. Williams:

Practically 75 per cent. of all cases of general paralysis exhibit proof of primarily syphilitic infection. The history of all cases is the "typical man of the world"—ambitious, fond of society and high living, a light sleeper and a heavy drinker; then come delusions and well-marked paresis. Four cases were noted where syphilitic teeth were prominent, although no history of syphilis could be obtained. Each one had used spirits freely. The pathologic conditions in chronic inebriety, syphilis and paresis are alike. The thickened membrane and meningeal changes are the same. The neurosis which predisposes to insanity, paresis or inebriety may be of syphilitic origin. A history of using alcohol exists in all cases of paresis, and it is significant of contributing causes not yet studied.—*American Medico-Surgical Bulletin.*

Hot Air as a Hemostatic.

The jet of hot air from a Holländer apparatus directed upon the bleeding surface of a kidney, liver, or severed blood-vessel, will arrest the hemorrhage by the formation of an eschar commencing around the edges and gradually spreading over the entire surface, mechanically checking the flow, in experiments upon animals, and Schneider concludes that it would be equally effective on man. The heat is only 30 degrees at 5 mm. from the apparatus, and hence is not sufficient to injure the organ. He found steam less effective and less convenient, for several reasons, masking the field of operation, etc.—*La Semaine Méd.*

Summer Diarrhea of Children.

The important dangers to be emphasized are too frequent feeding, overfeeding and the use of improper foods.

Holt states that during the hot weather it is an excellent rule to diminish each meal by at least one-third and make up the deficiency with water that has been boiled; to give water freely between—and to observe regularity in—feeding.

R.	Hydrargyri chloridi mitis	gr. i	06
	Sacchari lactis	gr. xii	72

M. et ft. chart. No. vi. Sig. One powder every half hour.

Indication.—Initial treatment to cleanse the intestinal tract.

℞.	Ol. ricini	ʒi	4
	Tinct. cinnamomi	gtt. i	06

M. Sig. To be given at one dose.

The cinnamon in the above prescription serves to detract from the disagreeable taste of the oil. It is also rendered more palatable by administering it to children in a little milk.

In these cases irrigation of the colon may be practiced with a solution of boric acid—3 per cent.—or with a saline solution —ʒii to the quart—a temperature of 80 F. When the stools contain mucus or blood, tannic acid—1 per cent. solution—can be substituted. Two or three irrigations can be made during the first twenty-four hours, then once a day thereafter.

℞.	Eudoxin	gr. xv	1

Ft. chart. No. xv. Sig. One powder three times a day before each meal—for a child of 1 year or older.

Eudoxin contains 52.9 per cent. of iodin and 14.5 per cent. of bismuth. It is odorless and tasteless, and can be given in a little boiled water.

℞.	Tannopin	ʒi	4

Ft. chart. No. xv. Sig. One powder three times a day one-half hour before nursing.

Tannopin is composed of tannin, 87 per cent., and urotropin, 13 per cent. It is a light-brown powder almost insoluble in water, and practically tasteless.

Dr. G. Joachim's experience with it is that it is innocuous and can be given without risk to the smallest infant in doses of 4 to 7 grains, three or four times a day.

℞.	Bismuthi subnitratis		
	Pulv. acaciæ, āā	ʒii	8
	Aquæ destil., q. s. ad	℥ii	64

M. Sig. Shake well. Teaspoonful every two hours.

Indication—After alimentary tract is free from all irritants.

℞.	Saloli		
	Cretæ preparatæ, āā	gr. xv	1

M. Ft. chart. No. xv. Sig. One powder every two hours for a child 2 years of age or older.

℞.	Naphtholini	gr. xxiv	1|5
	Pulv. acaciæ	ʒi	4
	Aquæ destil., q. s. ad	℥ii	64

M. Sig. Shake well. One teaspoonful every three hours for a child 1 year of age.

In the opinion of Hayward and Butler the antiseptic drugs give better results in the subacute and chronic diarrheas which subsequently follow summer diarrhea. They maintain that salol should be given when the symptoms point to affection of the upper bowel and naphtholin when the colon is chiefly involved.

℞.	Bismuthi subnitratis	ʒiss	6
	Bismuthi salicylatis	gr. xv	1
	Tinct. rhei aromatici	ʒss	2
	Aquæ destil., q. s. ad	℥ii	64

M. Sig. Shake well. One teaspoonful every three hours.

A combination of some of the bismuth preparations is recommended, as in the above, but none of them is superior to the subnitrate.

R.	Bismuthi salicylatis		
	Tinct. opii deodorati, āā	gtt. xv	1
	Syrupi simplicis	℥ss	16
	Aquæ cinnamomi, q. s. ad	℥ii	64

M. Sig. Shake. One teaspoonful every three hours for a child of 1 or 2 years.

Opium preparations should be avoided as much as possible. They are not indicated except when pain accompanies the diarrhea.

℞.	Tannigeni		
	Saloli, āā	gr. xv	1

M. Sig. One powder every four hours.

Tannigen is a compound of tannin and diacetyl, which is broken up only in an alkaline solution. It exerts its astringent action upon the duodenum and is strongly recommended by Bachus in cases in which an astringent is indicated. Moncorvo advises its combination with salol, bismuth salicylate or other antiseptics.

℞.	Tinct. opii camphoratæ		
	Syrupi rhei aromatici, āā	℥ss	16
	Aquæ calcis, q. s. ad.	℥ii	64

M. Sig. One teaspoonful every three hours for children over 3 years of age.

This is indicated when there are frequent bowel movements accompanied by pain.

℞.	Papain (carica papaya)	gr. xv	1

Ft. pulv. No. xv. Sig. One powder fifteen minutes before nursing, three times a day—to aid digestion of food.

℞.	Betanaphthol bismuthi	ʒi	4

Ft. chart. No. xv. Sig. One powder every four hours to a child 3 years of age.

This is best given in a little boiled water when the stomach is free from food.

℞.	Antipyrini	gr. viiss	5
	Syrupi aurantii corticis		
	Aquæ destil., āā	℥iss	48

M. Sig. One teaspoonful every two hours for a child 1 year of age or older.

The above may be given when there is gastric or intestinal disturbances accompanied by slight fever and in diarrheas of nursing children during dentition.

℞.	Tinct. krameriæ		
	Tinct. opii camphoratæ, āā	ʒii	8
	Misturæ cretæ, q. s. ad	℥ii	64

M. Sig. Teaspoonful every three hours for a child of 2 years.

Krameria possesses the same astringent properties as tannin and may be employed for the same purposes.

℞.	Bismuthi subnitratis	ʒi	4
	Pepsini saccharati	ʒss	2
	Zinci oxidi	gr. iv	25

Trit. et div. in chart. No. xii. Sig. One powder every four hours.

Tompkins (*Medical Record*) speaks favorably of the following as an intestinal antiseptic in these cases:

℞.	Hydrargyri chloridi mitis	gr. ii	12
	Zinci sulphocarbolatis	gr. iii	18
	Bismuthi subnitratis	ʒii	8
	Pepsini saccharati	ʒss	2

M. et. ft. chart. No. xii. Sig. One powder three times a day for a child 1 year of age.

Crandall states (*Archives of Ped.*) that opium in the diarrhea of children is contraindicated:

1. In the first stage of acute diarrhea, before the intestinal tract has been freed from decomposing matter.
2. When the passages are [illegible] and [illegible] odor.
3. When there is high [illegible] or [illegible] sympto[illegible] present.

4. When its use is followed by elevation of temperature or the stools become more offensive.

It is indicated:

1. When the stools are frequent, with pain.
2. When the passages are large and watery.
3. In dysenteric diarrhea together with castor-oil or a saline.
4. When there is undigested food in the stools and the bowels act as soon as food is taken into the stomach.

Medicolegal.

Seventy-Five Hundred Dollars for a Leg.—The Supreme Court of Minnesota holds, in the case of Thompson vs. Great Northern Railway Company, that, while certainly liberal, an award of $7500 damages to a conductor of about 40 years of age for the loss of his right leg, which had to be amputated below the knee is not so excessive as to justify any interference with a verdict therefor.

Gonorrhea Evidence of Illicit Intercourse.—The Supreme Court of Pennsylvania holds, in the case of Baker vs. Baker, where a wife sued for divorce, that if the husband had such a venereal disease as gonorrhea during the continuance of the marital relation, it must be regarded, in the absence of explanatory proof, as evidence of the fact of illicit connection with other women than his wife, there being no proof in the case that she was afflicted with that disease.

To What Dying Declarations Must Relate.—Dying declarations, being a substitute for sworn testimony, the Supreme Court of Appeals of West Virginia holds, in the case of State vs. Burnett, must be such narrative statements as would be admissible in evidence had the dying person been sworn as a witness. If they relate to facts to which the declarant could have testified, they are admissible in evidence. But mere dying declarations of opinion, which would not be received if the declarant were a witness, the court says, are inadmissible.

Abortion Compared with Second-Degree Murder.—The Supreme Court of Appeals of West Virginia declares, in the case of State vs. Lilly, that there is no crime more heinous against humanity or the Creator, than that of abortion. As compared with it, second-degree murder, it says, is commendable; for while the one has but one victim, and destroys only the body, the other has two victims, and destroys both soul and body. The proof of abortion, it also explains, rests usually on circumstantial evidence. And where an instrument is used to commit it, the court states that it is not necessary to a conviction to show the character of the instrument. More particularly, it holds, in this case, that, where the crime of abortion is fully established, and the circumstantial evidence establishes beyond a reasonable doubt the guilt of the accused to the satisfaction of the jury, the verdict will not be set aside because the evidence fails to show the character of the instrument, or the time when used to produce the abortion.

Appliances for Hospitals No Longer Duty Free.—The Massachusetts General Hospital has but just recently succeeded in obtaining from the United States Circuit Court of Appeals an affirmance of the decision which it secured in the circuit court, holding that surgical instruments designed and adapted for use in practical surgery are scientific instruments within the meaning of paragraph 585 of the tariff act of 1894, and that thereunder they were exempt from duty, when specially imported in good faith by the hospital, for use in its clinics and its training-school for nurses. Yet this is to be of little or no value to such institutions in making importations under the tariff act of July 24, 1897, if the Board of United States General Appraisers at New York is correct in its construction of paragraph 638 of the latter act. It points out that this is materially different from said paragraph 385, in its designation of the character of the society or institution permitted to import such instruments free of duty. A hospital, even with incidental educational features, such as the training of nurses and the giving of medical instruction to students, it holds, is not, within the meaning of said paragraph 638, an "institution incorporated or established solely for . . . educational . . . purposes;" nor is it a "college, academy, school, or seminary of learning;" and hence, it holds, surgical appliances imported for the use of such an institution are not entitled to admission free of duty under said paragraph.

Within Province of Medical Expert.—The United States Circuit Court of Appeals says, in Denver & Rio Grande Railroad Company vs. Roller, that the rule is well settled that a medical expert may form and express an opinion of the nature and cause of the bodily or mental condition of his patient—her ills, symptoms, pains and suffering—derived from his own knowledge, from his treatment and examinations, although based in part upon her statements and complaints made at different times as to her pains and suffering, and, in this connection, to give his opinion whether her injuries are liable to be permanent, and whether her present condition is due to or caused by sickness, injury, accident, or violence. Again, it says that when a hypothetical question assumes the existence of any state of facts which the evidence directly, fairly and reasonably tends to establish or justify, and does not transcend the range of evidence, it is proper to permit such questions to be answered, and it is not necessary that the questions shall embrace or cover all the facts in the case. But, it agrees, it would be reversible error to admit the answer of expert witnesses to hypothetical questions which assume the existence of facts upon which no evidence is offered.

Support of Insane Husband.—It is recognized by the Supreme Court of Iowa that it is the purpose and intent, under section 2297 of the code of that state, to make the property of those liable for the support of a public insane patient responsible over to the county for hospital expenses. The provision of this section relating to the liability of relatives imposes it upon a class, "those legally bound for the support" of the patient. Consequently, it has to be determined in each instance whether the individual sought to be charged is a member of such class. Now, is the wife obligated by law for the support of her husband? If not, she is not within the class made liable. Certainly no such obligation the court says, rested upon her at common law. Nor does it consider that she is made liable for the support of her husband by section 3165 of the Iowa Code, which imposes a liability upon her for family expenses. In other words, it holds that her liability for the support of her husband is not general, but is limited entirely to such matters as are of purely family benefit. Wherefore, it holds that maintaining the husband in an insane hospital is a kind of support for which the wife is not responsible, under the only section which imposes upon her any liability for the husband's expenses. The policy of legislation which requires one who has contributed in taxes for the support of the hospitals for the insane, to make full remuneration for care and treatment when calamity compels their use, is so doubtful in character, the court adds, that it does not care to aid it by construction, unless required by the manifest purpose and intent of the lawmakers. If it is the intent to subject the property of the wife to the payment of a claim of this kind, it should be clearly stated.

Judge of Necessary Frequency of Visits.—The Appellate Court of Illinois, second district, holds proper, in Ebner vs. Mackey, the following instructions: "The jury are instructed as a matter of law that the physician attending a patient is the proper and sole judge of the necessary frequency of the visits to his patient, so long as the patient is in his charge. And in an action for his services the physician is not required under the law to prove the necessity of his making the number of the visits that he makes and for which he is seeking compensation." In justification of this, the court mentions that there was no proof in this case that the physician came when he was forbidden to come, or that he was discharged and continued to attend thereafter, but that, instead, it was shown that the decedent, against whose estate a claim for medical services had been filed, and his wife had called him and acceped his services without question. In other words, the court holds that where a physician is called by a party to treat him or his wife, and he takes charge of the case and attends from day to day, evidently, in view of his responsibility for skilful and proper treatment, he must in the first instance determine how often he ought to visit the patient, and so long as the party employing him accepts his service and does not discharge him or require him to come less frequently, or fix the times when he wishes him to attend, he can not afterward be heard to say that the physician came oftener than was necessary. But were a person injured in a railway collision brought suit for damages, and sought to recover among other things his expenses for medical attendance, of course, the court says, he could not recover against the railroad company for all medical attendance he had chosen to have, but for such only as was necessary in curing his injuries.

Sufficiently Continuously Confined to House.—The strict letter of the contract of insurance against loss of time by sickness under consideration in the case of the Columbian Relief Fund Association vs. Gross, the Appellate Court of Indiana admits, should probably be taken as providing that benefits were to be paid only for the time the beneficiary was totally disabled from sickness, continuously confined to his house and under a physician's care. But it says that it can not agree with counsel for the insurer that the acts of the insured in going out of the house, under the directions and advice of a skilful and competent physician, to go to the latter's office for medical treatment, or even to get from twenty minutes to half an hour's exercise in the open air in his yard or on the pavement about and near his residence, was a violation of the conditions upon which he was to receive indemnity. Conceding such acts to be a violation of the strict letter of the contract, the court holds that they were not a violation of the spirit and true intent and purpose of the contract. It points out that the very acts complained of were done for the purpose of restoring the health of the insured, and thus ending his right to sick benefits. And it would be unreasonable, the court maintains, to compel a person so insured to place himself under a physician's care, and then deny him benefits for submitting himself to that physician's treatment. Furthermore, an agent of the insurer having requested that a particular physician be employed, and such physician having been employed, the court holds that on that account, especially, the insurer could not be heard to complain, though it says that it could not have been heard to complain had the insured followed the advice of a skilful and competent physician selected by himself.

Power to Regulate Sale of Cigarettes.—Whether dealing in and selling cigarettes is that kind of a business which ought to be licensed is, considering the character of the article sold, the Supreme Court of the United States holds, in the case of Gunderling vs. the City of Chicago, a question for the state, and through it, for the city, to determine for itself. An ordinance providing reasonable conditions upon the performance of which a license may be granted to sell such article, it declared, does not violate any provision of the federal constitution. Nor does it consider it a valid objection to an ordinance that it partakes of both the character of a regulation and also that of an exercise or privilege tax. So long as the state law authorizes both regulation and taxation, it says it is enough. The ordinance in question, which has obtained the sanction of this court, as well as previously of the Supreme Court of Illinois, in this same case, provides for the issuance of licenses by the mayor, upon application first made to the commissioner of health, and submitted to the latter, with his opinion as to the propriety of granting such license, accompanied by the evidence furnished by the applicant of good character and reputation, and upon the mayor himself being satisfied that the applicant is of good character and reputation and a suitable person to be intrusted with the sale of cigarettes, or that this is true of the person or persons in charge of its business, if the applicant be a corporation. It also requires a bond for $500 to be given, conditioned upon the observance of all state laws and city ordinances in force or that may be passed with reference to the sale of cigarettes, and imposes a license fee of $100 a year. But nothing contained in the ordinance, it expressly provides, shall be held to authorize the sale of cigarettes containing opium, morphin, jimson weed, belladonna, glycerin, or sugar. And having or exposing for sale, or offering to sell any cigarettes at any place within the city, without having first procured the license provided is made punishable by fine.

The Right of Property in Medical Records.—At a recent meeting of the Society of Legal Medicine, according to the Paris correspondent of *The Lancet*, M. Brouardel brought forward a most interesting point in reference to a matter upon which he had been consulted. A medical man died and his only son, also a medical man, entered into possession of his father's house and carried on the practice. He was anxious to consult certain notes and observations accumulated by his father which were stored away in the consulting room. But his step-mother (*belle-mère*) as co-heiress refused to let the son make use of the notes, ostensibly on the plea that she was anxious to avoid any violation of professional secrecy. M. Brouardel was of opinion that there would be no violation of secrecy, but simply a continuation of the trust from the first medical man to the second, who succeeded and who would take over the medical observations collected by his predecessor. A legal expert, however—namely, M. Danet—held a different opinion, and thought that all the notes and case-books should be burned. In face of this difference of opinion the question should be left to the courts to decide. In the course of the discussion at the Society of Legal Medicine M. Ladreit de la Charrière gave it as his opinion that a man who sells his practice has no right to communicate details as to the past medical history of his clients, because they may choose to go to some other medical man than the purchaser of the practice. M. Rocher said that French law did not recognize the sale of practices. *A fortiori* then, a medical man had no right to hand over to his successor details of patients without their consent. He agreed with M. Danet that the documents should be burned. M. Brouardel protested against his view, for if whenever a practitioner died all his notes were to be destroyed great injury would be done to the patients themselves and science would be deprived of a very valuable mine of collected knowledge. The matter was in the end remitted to a special committee, on the motion of M. Brouardel.

How Seriousness of Injuries Is to be Settled.—The appellate division, second department, of the Supreme Court of New York, holds that it was reversible error to permit physicians, who were examined as medical experts, to testify, in the case of Stoothoff vs. Brooklyn Heights Railroad Company, as to whether the plaintiff's injuries were serious. The only open question in the case was as to the amount of damages which he was entitled to recover from the defendant for those injuries. The physicians referred to, two in number, had apparently examined him for the sole purpose of testifying, and had given evidence, based necessarily, to some extent, upon subjective symptoms, to the effect that he was suffering from a severe sprain of the muscles or ligaments of the lumbar region; that the muscles on the left side of the spinal column were in a condition of spasm, which the slightest touch would exaggerate; and that there was a sprain or wrenching of the spine. Now, the court says it was entirely competent for the physicians, in addition to stating what they found on the physical examination of the plaintiff, to state fully and in detail the nature and extent of his injuries, their effect upon his person and his system, the pain and other suffering or inconvenience to which they would subject him, the nature of the treatment required, and its probable results, and their opinion of the permanency of the injuries and their effects, so far as they were able to give it with reasonable certainty. With this information it thinks that it would be as possible for the jury as the physicians to determine whether the injuries were serious, and to fix the precise degree of seriousness of the injuries in the plaintiff's case, and with special reference to his life and occupation, as they were required to do by law in order to assess the damages. On the other hand, it says that the jury would be aided little if the plaintiff could rest upon the general characterization of his injuries by his physicians as "serious" and the defendant in turn depend upon an equal or greater number of physicians who would characterize them as "trivial," while all effective review of the propriety of the result would be precluded. The nature of the case, it holds, required no such result.

THE ETIOLOGY AND SYMPTOMATOLOGY OF RUBEOLA.

While rubeola bears some resemblance to both measles and scarlet fever, and has been considered as a mild variety of one or the other of these diseases, it is now pretty generally agreed that it is an independent affection, one attack of which usually confers protection from a subsequent attack of the same disease, but not from a subsequent attack of measles or scarlet fever, while the latter, in turn, confers no protection from rubeola. The disease pursues a mild and short course, generally without serious complication or sequel, and its greatest importance resides, perhaps, in the danger of confusion between it, on the one hand, and scarlet fever and measles on the other. Some interesting facts of an etiologic and symptomatologic character noted in the course of contemporaneous epidemics of rubeola and measles, are recorded by Tobeitz[1].

The epidemic of rubeola began in December, 1898, and terminated early in July, 1899, 719 cases in all being observed, and reaching its height in February, when 275 cases occurred. The epidemic of measles began in June, 1898, and continued until May, 1899, 3273 cases coming under observation, the largest number, 614, in January, 1899. It was seen that the predisposition to measles was in general much greater than that to rubeola. The cases of the latter were pretty evenly distributed between the two sexes, although after the period of puberty the disease appeared to be a little more common in females. Measles was the more common disease until the age of 6, and rubeola the more common after that period of life. This distribution is partly due to the fact that measles having occurred in a large number of cases in early life, the patients were protected from subsequent attacks later in life. The school was clearly shown to be an especially frequent medium for the conveyance of the infection, the number of cases coming under observation declining with the advent of the summer vacation and again increasing with the resumption of school sessions. Second attacks of rubeola occurred in eighteen cases—2.5 per cent.—while second attacks of measles occurred in but fifteen cases—0.46 per cent.

It was not found that the predisposition to infectious diseases in general, or recovery from such diseases, increased the predisposition to rubeola. Among 719 cases of rubeola there were only 146, 20.6 per cent., in which there had been previous infectious disease within two years. Such information as could be gathered with regard to the period of incubation of rubeola indicated that this is extremely variable, and apparently not fixed, but dependent upon individual and extrinsic influences.

A study of the symptomatology in 80 cases disclosed the presence, almost unexpectedly, of no other manifestations than the exanthem and the enlarged glands. Although it is possible in almost all cases of measles to determine where and when infection took place, it was rarely possible to do so in cases of rubeola. No symptoms were observed during the period of incubation. The enanthematic stage was in but few cases attended with catarrhal symptoms referable to the upper air-passages and the conjunctiva, while in some there was also slight diffuse redness of the pharyngeal structures. The irregular rose-red enanthem, as large as the head of a pin, that has been described as of significance in the differentiation from measles, was not observed. Almost unexceptionally the cervical and post-cervical glands were found enlarged, and with especial frequency and characteristically those over the mastoid process, during the course of the disease also in children that had previously exhibited glandular enlargement. Not rarely some of the enlarged glands were slightly painful. Fever and catarrhal symptoms were generally absent during the stage of exanthem, or scarcely worthy of mention. No case was attended with complications.

The exanthem generally appeared in the form of small spots, with large efflorescences, beginning in the face, and extending in a few hours to the remainder of the body. The distribution and the density of the eruption exhibited marked individual variations. In two cases the eruption was so dense and so fine as to resemble wholly that of scarlet fever, but apart from slight fever at the beginning, and enlargement of the glands, no other symptom of scarlet fever was present, and the eruption disappeared as quickly as the usual form of exanthem. Slight pigmentation of the affected skin was observed in numerous cases, but never desquamation. Four cases presented large spots, principally confined to the face and the extremities, and of long duration. These slight variations are, however, to be explained by temporal, local, or even individual conditions acting upon the biology of the hypothetic, pathogenic micro-organism.

STATISTICAL STUDY OF CARCINOMA OF THE LIP.

Loos[1] presents statistics of 565 cases of carcinoma of the lip treated in v. Brun's clinic. The figures cover fifty-five years, and the present study is a continuation of Wörner's work, which dealt with 305 cases in the period between 1843-84. Loos now adds 260 cases and brings us down to 1898. Some of the principal facts are recapitulated here in order to show the undoubted value of careful overhauling of material of this kind as well as the eminent desirability of better systems for recording the work of our large surgical clinics—a matter that we believe is now greatly neglected in not a few centers of surgical activity in this country. There is undoubtedly a singular dearth in our periodical literature of careful studies of common surgical affections covering long periods and dealing with the accumulated observations of large clinics. Such reviews throw much light upon the course of disease and upon the value of operative and other forms of treatment.

---

[1] Archiv f. Kinderheilk., Bd. xxxviii. H. 5 u. 6, p. 386.

[1] Beitr. zur Klin. Chir., 1900. B. cxxvii, p. 57.

The figures of Loos show that carcinoma of the lip is more frequent in men than in women—85.5 per cent. of his cases were men, 14.5 per cent. women. The lower lip was involved in 534 cases, the upper only in 31. The average age is 60 years; cancer of the lip may occur at any time between the ages of 22 and 80, but the maximum of frequency lies between the sixty-sixth and seventieth years of life. There is no essential difference in the rate of growth in the different periods of life. Sixty-three per cent. occurred in agricultural people. It may be comforting to smokers to learn that this mode of using tobacco does not bear any evident relation to labial carcinoma. Heredity seems to be of little import also. A history of an insignificant trauma is common. The usual starting-point is on the red aspect of the lip, but without reference to any particular part of this surface. The time between the beginning of the growth and operation averages eighteen months in the case of the lower lip and three years in the upper. Submaxillary and submental glandular metastasis occurred in three-fourths of the cases, and metastasis usually took place from three to six months after the appearance of the tumor. Distant metastases were rare.

Of the 534 carcinomas of the lower lip, 484 were operated upon and 50 were not. The unoperated cases were most of them unoperable when they came under observation. Healing and cosmetic and functional results of the operations are said to have been satisfactory. Relapse occurred in 33 per cent. of the cases involving the lower lip, the average length of time after operation at which relapse took place being six months. Only one-tenth of the relapses occurred after three years, and in these instances the carcinoma may have been of new growth. Operation on relapses gave favorable results in 11.7 per cent., on second relapses in but 1.1 per cent.; showing that even here life is undoubtedly prolonged by operation. The mortality from operations was 6.2 per cent. from 1843-1885, from 1885-1898 0.4 per cent. General results are well shown in this tabular statement:

	1843 till 1885.		1885 till 1896.	
	No.	per cent.	No.	per cent.
Living	25	10.2	65	46.1
Dead without return......	102	41.4	28	19.9
Living with return........	0	0	6	4.3
Dead with return..........	103	41.9	41	29.1
Dead from operation......	16	6.5	1	.6

In other words, from 1843 till 1885 the result was favorable in 51.6 per cent., unfavorable in 48.4 per cent: from 1885 till 1898 favorable in 66 per cent., unfavorable in 34 per cent.—a gain for the latter period of 14.4 per cent. In the carcinomas of the upper lip the result was favorable in 72.2 per cent., unfavorable in 20.8 per cent.

The reliability of these statistics must be regarded as almost beyond question, because accurate information in regard to subsequent events in the cases operated on was secured in all but ten instances—a remarkable success.

VENOUS THROMBOSIS AS A COMPLICATION OF CARDIAC DISEASE.

In the "Festschrift" in honor of Jacobi is an important article on this subject by William H. Welch. He first describes an instance in a girl of 17 years, with chronic mitral and aortic endocarditis following acute articular rheumatism, and giving rise to regurgitation and eventually to cardiac insufficiency. During the last days of life a painful edema of the left arm made its appearance. Post-mortem, in addition to the cardiac lesions and their usual secondary effects, an infectious —streptococcus—thrombus was found filling the innominate, subclavian, axillary, and lower parts of the jugular vein. He then gives the clinical history of three other, more or similar cases from Dr. Osler's wards, but without post-mortem examination. In one case, a case of mitral stenosis, thrombus of the left jugular, axillary, subclavian, and innominate veins gave rise to a hard, painful edema, lasting for nearly three months before gradually disappearance set in.

From the literature Welch collected reports of twenty-three cases of peripheral venous thrombosis in cardiac disease. From a study of the twenty-seven cases thus grouped together he finds that in twenty-three the thrombosis involved the large veins of the upper extremities or the neck, or both, mostly of the left side; only four were thrombosis of the veins of the lower extremities. He suggests that probably many thromboses of the veins of the lower extremities are overlooked because of the greater edema of these parts in uncompensated heart disease. Of the twenty-three cases of thrombosis of the veins of the arms, neck and chest, the large majority—17—occurred in the female sex; nearly one-half of those whose ages were stated were between 15 and 30 years of age; in twenty the valvular lesion was mitral, of a chronic character, the cases of mitral stenosis, with or without insufficiency, taking the lead. "The preponderance of females and of patients under middle age is thus, at least in great part, explained." In most of the cases the thrombosis appeared during failure of compensation. The veins of the right side alone were affected in but two cases; of the remaining twenty-one cases fourteen were unilateral, seven bilateral. The superior vena cava was thrombosed in six cases. The commonest point of origin of the thrombus was the bulb of the left internal jugular vein. Chronic disease of the ve [illegible] dently is of little import in [illegible] on of [illegible] of thrombosis. The pr [illegible] s. pain, tenderness, edema an [illegible] and distribution of the edema varied considerably in the different cases, and the swelling was often hard. Nineteen of the twenty-three cases ended in death, the grave prognosis being mainly the natural result of the extreme failure of compensation of the valvular lesion during which the thrombosis develops. It will be seen that venous thrombosis of the arms and neck, especially of the left side, in cardiac disease forms a fairly distinct group with features of special interest, and this is the main reason for calling attention to Welch's interesting article.

As regards the causation and special localization of venous thrombosis complicating cardiac disease, Welch lays stress on the one hand upon disturbances of the circulation especially liable to affect the veins of the left side of the neck, the greater length and obliquity of the left innominate vein hindering the return flow in this vein (Hanot and Parmentier), the difficulty being further increased by pressure on the left subclavian vein from the dilated left auricle and dilated pulmonary vessels in mitral disease; and on the other hand, he emphasizes the eddying motion of the blood set up in heart disease in the bulbous enlargement of the lower end of the internal jugular and in the adjacent veins by the coming together of blood-currents from different directions and with different velocities and pressures. These conditions explain why certain veins are the seat of election for thrombi. Based upon the presence of streptococci in the first case studied, Welch suggests that bacteria probably constitute the exciting cause of this form of thrombosis.

THE ASSASSINATION OF KING HUMBERT.

Regicide has been shown to have been committed, in a large proportion of cases at least, by persons of weak or unbalanced minds. This was notoriously the case with the assassins Guiteau and Prendergast in this country, who worked without accomplices, following out the dictates of their own insane delusions. In times of great excitement it is very natural to suppose that some ill-balanced individual without being actually insane might commit a crime and the responsibility be somewhat questionable under the circumstances. When, however, such a crime is the result of a conspiracy of a number of individuals, as in the case of the assassination of President Lincoln and of the Emperor Alexander, it is somewhat different. The assassination of King Humbert, which has just occurred, appears to belong more to this class than to that of the irresponsible lunatic homicides. The assassin in this instance seems to have been an adherent of a body that is at present endorsing his action, and the suspicion of a widespread conspiracy is certainly justified in such a case.

The question arises: How far are we to consider the possible lack of balance of the individual as mitigating his responsibility? We may say that "the anarchistic virus entered his ill-balanced brain," but if we are to excuse him what are we to say of the sources of this virus? It is a psychologic fact that in combination men will commit crimes that individually they would abhor, and in time of popular furor or hysteria we may look for just such acts. There are some signs that at this end of the nineteenth century we are passing through a sad period of popular hysteria, of which this event may be one of the evidences. It is not so wide a step between the socialism that leads a prominent professor of economics to justify the violence of strikes and the anarchism that advocates the murder of kings simply because they are kings. The trouble is that such crimes, in such conditions, become contagious; a suicide club or a band of anarchistic assassins may only start the ball, but they will find many really irresponsible imitators who will keep it rolling. This is one important aspect of the case from the medico-psychologic point of view, but it shows a danger that statesmen and every good citizen should guard against. The death of King Humbert is to some extent a danger sign to every one in a prominent position, we trust not a serious one, but one that nevertheless should not be ignored.

Another question arises in connection with this subject, and that is: Are not some of us going a little too far in seeing a pathologic side to all criminality? It is very easy to say that criminals, as a class, are degenerates, as compared with non-criminals. We can also say that every one that does not follow a rational utilitarian moral standard is defective in his mental balance or self-control. We are not arguing here for the condign punishment of lunatics, but simply for a reasonable estimation of responsibility which is not always lost because the individual possesses certain mental and physical defects. There is sometimes a sentimentalism even in medicine that has very little practical use in such cases as these.

EIGHTEENTH CENTURY MEDICAL EDUCATION IN ENGLAND.

The presidential address of Dr. Elliston before the British Medical Association, which we give in abstract in this issue, contains a very interesting history of the leading facts of British medicine from the earliest times down to the present. Some of these are medical curiosities and all will be of interest to our readers. It seems a little strange to learn that medical education was so backward in England up to so recent a period and that the regular medical college hardly existed before the middle of the eighteenth century, if indeed it did then. From the history of American medicine, comparing it with this, we can see that the early medical pioneers of this country were fairly representative of their confrères in Great Britain. Dr. Osler's prophecy, noticed in one of the recent issues, that the time will come when transatlantic students will look to this country for their inspiration, is, we hope, in the near future.

LODGE PRACTICE.

Lodge practice seems likely to become a factor in politics in British Columbia. The local medical society of Victoria passed a resolution agreeing not to consult with lodge doctors, which was agreed to by all the local profession. Then the lodges proposed to import physicians, but were saved this trouble by the defection of two members of the association. This, of course, is only a partial relief and now they are proposing to make a political issue, the repeal of the provincial medical-practice act, which they claim puts it in the power of the local profession to debar from practice whomsoever they may choose. This insinuation of unfairness by the medical examining board is resented of course, but it will be used probably for all it is worth as a political pretext. One feature of the trouble is the acrimonious correspondence in the newspapers by one of the two seceding physicians, Dr. Ernest Hall, who has some reputation for his claims of curing insanity by gynecologic operations. So far as we can judge from the reports, the members of the local profession are acting in a perfectly legitimate and commendable manner and the outcome will not be to their disadvantage if they work harmoniously and stay together.

THE CALL TO TEACH.

The *Post-Graduate,* in its July issue, remarks that it has no sympathy with the "mute inglorious Miltons" of the medical profession who want to be professors and can't. Every man, it says, "has his chance here." We should think he had. The Journal once made an estimate of the proportion of medical professors to the general profession in one of our great medical centers, and found that about one physician in every five and a half held some position on one or more medical faculties, and some had three or four. This, too, without counting the extreme irregulars outside of the three recognized schools of medicine, and the carpenters, waiters, *et id omne genus* who are on the faculty rosters of the diploma mills. The remark of Dr. Austin Flint, quoted by the *Post-Graduate,* that there is always "a place in some medical college for every man who could really teach," is the very mildest kind of truth; it does not cover half the facts. The question as to the effect of this facility on the welfare of the medical profession generally is hardly ever raised, certainly not by the multitudinous professors. A call to teach, like a call to preach, can not be disregarded; there are comparatively few that have it on their conscience that they have ever refused one, and the medical propaganda goes merrily on.

THE PROGNOSIS OF TUBERCULOUS MENINGITIS.

Recovery from tuberculous meningitis has been recorded quite a number of times. In the older cases of this kind bacteriologic confirmation of the diagnosis is lacking, but in many the clinical course of the disease and the name of reporter offer a certain guarantee of its correctness. In some cases subsequent autopsy disclosing calcified tubercles in the spinal and cerebral leptomeninx has placed the diagnosis beyond doubt. Freyhan, and recently, Henkel[1] have recorded cases of recovery from clinically typical tuberculous cerebrospinal meningitis in which the diagnosis was clinched by the demonstration of tubercle bacilli in the cerebrospinal fluid obtained through lumbar puncture. In Henkel's case, a 10-year-old boy, there was optic neuritis and paresis of the ocular muscles. The disease presented more or less typical and active symptoms for about two weeks, when a gradual improvement began, some fever persisting for several weeks. The first attempts to walk showed a tendency to tumble to the right, but this also passed away. In the fourth week the hair began to fall out. The treatment consisted of a few small doses of calomel and daily baths. The prognosis of even tuberculous meningitis consequently admits of a ray of hope.

TRADES UNIONISM AND PHYSICIANS.

As a natural suggestion from recent events that have largely occupied the attention of the public, it may not be out of place to casually notice the charge frequently made, and recently elaborated by a labor periodical, that the medical profession is organized and acts on trades-union principles. The chief basis for this is the desire and effort of the profession for laws regulating medical practice, which, the trades unionist assumes, correspond to his own methods. If trades unions required nothing more than that a man should know his business, and did everything in their power to multiply their competitors; if they set up free dispensaries for giving out their services gratis; if they never struck, and, least of all, when their services were most demanded, and did a large part of their work gratuitously for the deserving and the undeserving, made no limits as to hours, but served willingly at all times, pay or no pay, then there might be some comparison between them and the medical profession. As the case stands, it is the grossest misrepresentation to say that there is any resemblance between them whatever. A strike of doctors in time of an epidemic or emergency would be a sight for gods and men, an interesting object-lesson of the beauties of the procedure, and would call into action the vicarious virtue of the social reformers as nothing else could. Even an attempted organization against the dead-beats to refuse them credit, works up the lay press into virtuous indignation against the inhumanity of the mercenary doctors. No one would wish the medical profession to repudiate any of its honorable traditions or become less altruistic in its motives and methods. It would be directly in the right line, however, if a very large proportion of its members could adopt a self-denying ordinance against taking professorships and multiplying medical colleges.

THE PERCEPTION OF THE BLIND.

In the *Doctors' Magazine* for July is an article by Frederick Boyd Stevenson giving an account of certain inmates of the Illinois Industrial Home for the Blind, who, though totally blind, possessed the faculty of recognizing objects, to a certain extent, without the apparent aid of the other senses. Thus, one could tell when he was approaching a tree or a curbstone and could even recognize the different individuals in the room. But if he was expecting to meet persons he could not tell whether any one was in the room or not. Similarly, if the electric light was turned on unexpectedly he was aware of it, but if it was announced beforehand he could not recognize the difference. Attention or expectation seemed to destroy the peculiar perceptive faculty possessed by the individual, which seems, therefore, to depend somewhat on the untrammeled exercise of all the powers of unconscious sentience or of some special as yet unrecognized faculty called into action by the deprivation of sight. This last is what is most readily assumed, but whether correctly is a question. Stevenson adopts this view and quotes some reported facts of somnambulism as being at least suggestively explanatory. Just how perceptions reach the conscious centers is not always clear and there may be possibilities as yet unthought of. The case of the perception of light through the nose reported a year or two ago is in point. It hardly seems necessary, however, to admit more perhaps than a sharpening of the unconscious sensory cerebration which we utilize in every movement and function, but which in the full use of our senses may not be called into action. This may not be an adequate explanation, but it suggests itself as being as reasonable as any. The perceptions of the blind are a subject not yet fully exhausted by the psychologists.

---

[1] Münch. Med. Woch., 1900, No. 23.

FAITH CURE, CHRISTIAN SCIENCE, ETC.

Every generation, perhaps every decade, seems to have its fad or fads, and the recent past has not differed from remote antiquity in this respect. A certain period evidently is required for the public to realize its mistakes, but such a fondness does it have for the mysterious and the unreal, so anxious is it to be deceived, that it no sooner drops one delusion than it takes up another. We have thus had within the present century Perkinism, Mesmerism, Keelyism, Eddyism, faith-cure, osteopathy, etc. We have, perhaps, entered on an era of "suggestive therapeutics." Most of those mentioned are dead or already dying, and we must await with patience the advent of the next. Sometimes the public awakes, thinks, lets its passion run unbridled and overcome good judgment and then something happens. In an Ohio town a self-styled divine healer of the Dowie stripe, under whose ministrations several infants had died and other disastrous consequences had resulted, was taken from his hotel, stripped naked, and was about to be tarred and feathered, when the police interfered, although the man was almost killed in the conflict. An illustration of the extremes to which the faith-cure delusion may be carried was brought to light recently in Philadelphia in consequence of the death of a child 7 months old from convulsions during dentition, for which no medical attention was provided, because, in the language of the man to whom its care was entrusted, "it is against our religious principles. We are children of God, and believe in the cure of disease by prayer." In reply to an inquiry by the coroner, who was called upon to investigate the cause of death, as to who had suggested the establishment of the "Orphanage" in question, the answer came: "The Lord by His spirit." The jury to whom the case was submitted took a less spiritual view of the matter and rendered a verdict of death due to criminal neglect, and the principals were committed to prison to await trial on this charge. Even this, however, failed to cause dismay, as "deliverance through faith" from such a little annoyance was confidently hoped for. Instances of the sort related have become far too common, but similar summary treatment would go a great way to diminish their frequency.

Medical News.

A Bureau of American trained nurses has been established at 102 rue Vaugirard, Paris, under the direction of Mrs. W. H. Booth.

The druggists and physicians of Hamburg, Germany, have appointed a committee of six members to devise measures to check the spread of quackery.

At the Centenary of the Royal College of Surgeons July 26, diplomas of honorary fellowship were presented to Drs. W. S. Halsted, Baltimore; W. W. Keen, Philadelphia; R. F. Weir, New York; J. Collins Warren, Boston; I. H. Cameron, Toronto; and Sir W. H. Hingston and T. G. Roddick, Montreal.

An order drafted by the marine-hospital service was promulgated by the President July 28, establishing a national quarantine against Cape Nome and Dutch Harbor, Alaska, on account of epidemic smallpox at these points. Supervising Surgeon-General Wyman has notified the surgeons at these places of this order and has directed its strict enforcement.

Dr. S. A. Knopf, of New York, has been awarded the prize of 4000 marks offered by the International Congress on Tuberculosis, of Berlin, for the best essay on "How to Fight Tuberculosis As a Disease Among the Masses." Eighty-one essays were offered in competition. We believe this is the second international prize on tuberculosis that has been won by Dr. Knopf.

Red Cross Nurses.—Dr. Anita Newcomb Magee, lieutenant in charge of the corps of female army nurses, says that there are now 145 army nurses, practically all of whom are on duty in the Philippines, or on their way there. A bar to the sending of army nurses to China has been suggested, namely, that as China is not a party to the Geneva convention, she might not treat nurses as non-combatants.

The British Medical Association.—From the various reports submitted to the council of the British Medical Association and which were presented at the annual meeting this week, we abstract the following: The number of members of the British Medical Association last year was 18,185; during the year 957 new members were elected, 231 died, and 529 resigned or were taken off the list for arrears, leaving on the books

18,382, a net increase for the year of 197. The total revenue for the year ending Dec. 31, 1899, was £43,263, about $216,000. The expenditure was £36,981, leaving a surplus of £6272, a little over $31,000. The excess of assets over liabilities at the end of 1899 was £75,994, about $374,000. There are thirty-eight home Branches, which are reported in a healthy condition with membership increasing. The Colonial Branches, however, are causing the council anxiety, as these are not thriving, not a few being dormant. The Western Australian Branch is flourishing, and has successfully influenced medical legislation.

ILLINOIS.

Dr. Gurdon A. Potter, Belvidere, has been appointed a surgeon by the Navy Department.

Cases of ivy poisoning have been so numerous recently in Evanston that the inhabitants have begun a war of extermination on the dangerous plant.

Chicago.

Dr. L. Harrison Mettler is on a trip through the Northwest with his bride.

St. Luke's Hospital has received a bequest of $5000 from the late Mrs. Effie McKindley.

Merck & Co. announce that they have opened a branch house at 227 Randolph street, under the charge of Mr. J. W. Parry.

Dr. E. R. Moras, who was married July 20 to Miss Anna Stamm, is in Europe on his wedding journey. They will remain until the first of December.

The Diet Kitchen, which was opened in June for the purpose of supplying pure food and milk for infants, has thus far fed 414, and the number applying for medical aid and food is rapidly increasing.

The report of an epidemic of smallpox at Chicago Heights has been investigated by Dr. Meyerovitz, of the State Board of Health, who finds one case of smallpox and sixteen cases of scarlatina. On the principle of locking the stable door after the horse is stolen, the citizens have held a mass meeting to consider the improvement of the present primitive sewer-system.

ALEXIAN BROTHERS' HOSPITAL.

The annual report of this hospital for the year 1899, has just been issued. It shows that the patients in the hospital on Dec. 21, 1899, numbered 174, and the number received during the past year was 2406, making a total of 2580 patients treated at the hospital during 1899. This shows an increase in the number of patients at the hospital during 1898 of 15 per cent. The report also shows that during 1899 1714 patients were cured, 354 improved, 86 not benefited, and 184 died. Those received at the hospital during the year in a dying condition numbered eighty-two. Of the total number of patients, 1549 were single, 745 were married, 286 were widowers. Among them were 1486 Catholics, 948 Protestants, 39 Hebrews and 107 who professed no religion at all. The average age of the patients was 47½ years.

ILLINOIS RIVER WATER.

Peoria, and not Chicago, is said to pollute the water of the Illinois river. The State Board of Health has made sanitary investigations of the Illinois river and its tributaries both before and after the opening of the drainage canal. The preliminary report, based on analyses made by Professor Long, of the Northwestern University Medical School, shows that the waters of the lower Illinois river, at least, are not polluted by the flow from the drainage canal. He considers the cattle-shed filth of Peoria and not the Chicago sewage as the main factor in the pollution of the lower river. This is a confirmation of the results obtained after analyses of water from the Chicago River and Illinois and Michigan Canal, made in 1879, by Dr. S. C. Stanton, who found marked increase in organic impurity below towns and cities, which extended, however, for only a short distance. At Summit, for instance, only eight miles from Bridgeport, there was less organic impurity than was found the same distance below Joliet.

HEALTH DEPARTMENT.

Chief Sanitary Inspector Young has started a vigorous crusade against unsanitary rag and junk shops. Warning notices have been sent to all dealers, and should they not comply with the regulations of the Department, arrests will speedily follow.

No case of smallpox has been reported during the past week and the Isolation Hospital contains only one patient, who will probably be discharged in a few days.

The weekly bulletin for the week ended July 26 still shows an exceptionally low mortality. The total deaths from all causes were 438, a reduction of 16 from the previous week's record, and of 108 from the corresponding week of 1899. The comparative death-rate per thousand for the same periods is, 12.33, 12.78 and 16.24. The deaths of males were 247, of females 191. Under one year of age 153 died; between 1 and 5 years, 43; and over 60 years, 56. The principal causes of death were: Acute intestinal diseases, 121; consumption, 61; heart diseases, 26; Bright's disease, 20; pneumonia, 18; nervous diseases, 15; cancer, 10. No deaths from sun-stroke were reported; 4 committed suicide and 19 deaths were due to violence. Births reported during the week were 565; 288 males and 277 females.

The contagious cases reported were 47, of which 22 were scarlatina, 23 diphtheria and 2 measles. The Department laboratory analyzed 557 samples of milk, 5.20 per cent. of which were found below grade.

The report of mortality for the month of July shows a very marked improvement over the corresponding month of last year. The total deaths were 2069 or a mortality of 13.91 per thousand, as compared with 2360, or 17.39 per thousand mortality in 1899. These figures are based upon a population of 1,750,000, and the death-rate per 1000 would be correspondingly lower if the figures of the census of 1900 had been used. The deaths by sexes were: July, 1900, males, 1149; females, 920; July, 1899, males, 1332, females, 1028. Under 1 year, 616 died; between 1 and 5 years 224; and over 60 years 300 in July 1900; the figures for July, 1899, were respectively 795, 328 and 295. The principal causes of deaths for the month in 1900 and 1899 were as follows: Acute intestinal diseases, 447-702; apoplexy, 27-24; Bright's disease, 96-91; bronchitis, 42-45; consumption, 237-198; cancer, 69-80; convulsions, 53-57; diphtheria, 41-47; heart diseases, 133-125; nervous diseases, 149-124; pneumonia, 92-116; typhoid fever, 26-41; scarlet fever, 10-20; suicide, 25-37; violence, 110-135.

In commenting on these figures, Dr. F. W. Reilly, assistant commissioner of health, remarks:

"As compared with July, 1899, there is a decrease of 30 per cent. in the deaths of infants and children under 5 years of age, and of 41 per cent. in the deaths from the impure-water diseases. It is yet too early to demonstrate by the disease and death-rates the effect of the heavy rainfall of last week, when nearly an inch and a half fell in eleven hours. The records and charts of the Department for years show that such a rain, without exception, polluted the water-supply and caused a marked increase of acute intestinal deaths during the following seven or eight days and of the typhoid-fever deaths within the following four or five weeks. According to the chemical examinations the water-supply has not been polluted by last week's rain, nor has there yet been noted any increase of the impure-water diseases. There is no obvious cause for this gratifying departure from the usual results of a sewer-flushing rain other than the action of the drainage channel. From the standpoint of the public health and the saving of human life the cost of the channel is the best investment Chicago ever made."

PENNSYLVANIA.

Philadelphia.

Dr. Henry D. Beyea has sailed for Paris.

Dr. Albert E. Roussel will spend the summer at Cape May.

During the summer Dr. Henry Beates and Dr. H. A. Hare will cruise along the Atlantic coast.

At the last meeting of the Royal College of Surgeons of England, held July 27, Dr. W. W. Keen, of this city, was elected to honorary fellowship.

The **corner-stone** of the new annex of St. Mary's Hospital was laid July 25. The new addition will cost about $100,000.

On July 30 an entertainment was given at Swarthmore for the benefit of the Rush Hospital for Consumptives and the Pay Hospital for Contagious Diseases.

Dr. John H. Garvin and **Dr. George Erety Shoemaker** have been appointed gynecologists to the Presbyterian Hospital to serve six months each. A vacancy was caused by the death of Dr. R. M. Girvin.

Dr. H. W. Stelwagon, clinical professor of dermatology in Jefferson Medical College, has gone to Europe. After attending the International Medical Congress in Paris he goes to Copenhagen to study the treatment of cutaneous diseases by concentrated light rays, at the Finsen Institute.

MORTALITY STATISTICS.

The number of deaths reported for the week just closed was 514, a decrease of 50 over the previous week, and an increase of 33 over the corresponding period of last year. The principal causes of death were: apoplexy, 13; cancer, 13; cholera infantum, 75; consumption, 75; pneumonia, 24; sunstroke, 26; marasmus, 31; diphtheria, 8; scarlet fever, 1; typhoid fever, 12.

ADULTERATED FOODS.

Two wholesale dealers were, during the past week, held in $400 bail, both being charged with selling adulterated spices, and one with selling "renovated" butter. In this connection it is said that the Bureau of Health of this city has received instructions from Harrisburg to act with the state authorities in suppressing the practice of adulterating foods.

FREE FROM SMALLPOX.

Colonel J. Lewis Good, chief of the Board of Health, announces that the last case of smallpox confined in the municipal hospital has convalesced and that the city is now entirely free from the disease. The quarantine in the negro settlement, where there was a recent outbreak of the disease, has been raised. None of the affected have died, showing its mild type.

ST. TIMOTHY HOSPITAL.

The managers have acknowledged the receipt of $10,000 from J. Vaughan Merrick for the purpose of extinguishing the ground rent of the hospital, which amounts to about $8000; $2000 will go toward the endowment fund. The hospital has also received the sum of $5000 from John H. Dearnley for the purpose of endowing a free bed in memory of his daughter, Martha A. Dearnley. A gift of $50,000 has also been received from the estate of Percival Roberts, which will go toward defraying the cost of the addition to the hospital, now in the course of erection.

WILL OF DR. JOHN ASHHURST, JR.

The will was admitted to probate on July 24. To his widow, Sarah Wayne Ashhurst, is devised as many books from his library as she may wish. A codicil provides that the College of Physicians shall have the right to select 1500 volumes from his medical library. Future editions of his "Principles and Practice of Surgery" have been entrusted for editing, revision, etc., to the care of Dr. Richard H. Harte, assisted by Dr. William W. Ashhurst and Dr. Astley P. C. Ashhurst. A conservative estimate of the value of the estate has been placed at $190,000.

NEW YORK.

Dr. C. C. Harvey, Dundee, sailed for Europe, July 21.

Dr. Marcel Hartwig has been elected president of the Buffalo Academy of Medicine.

Dr. Clarkson Scuyler, of Plattsburg, has offered a yearly prize of $100, to be awarded for the best essay written by a graduate of the Albany Medical College. The subject for next year is "The Influence of the Discovery of the Relation of Bacteria to Disease on the Practice of Medicine Exclusive of Surgery." Essays should be sent to Dr. S. B. Ward, Albany, before March 1, 1901.

FAYERWEATHER BEQUESTS.

The decision of the Fayerweather will case was rendered on July 12, and the will declared valid. By its terms $210,000 is bequeathed to the Woman's Hospital; $50,000 each to St. Luke's and the Presbyterian hospitals, and $25,000 each to Mount Sinai and the New York Cancer hospitals, the Methodist Hospital, Brooklyn; the Manhattan Eye and Ear Hospital, the New York Eye and Ear Infirmary and the Montefiore Home for Chronic Invalids.

ALBANY MEDICAL COLLEGE.

The faculty of the college has announced these appointments: Arthur G. Root, professor of diseases of the nose and throat; George Blumer, adjunct professor in histology, pathology and bacteriology; Arthur Wells Elting, instructor of surgery and master of surgical clinics at the Albany hospital; Harry Judson Pines, lecturer in obstetrics; Edgar Roscoe Stillman, of Troy, instructor of physiology; Edgar Albert Vander Veer, instructor in surgery; James Wesley Wilsie, instructor in materia medica; Lansing Betts Winne, instructor in clinical medicine; Warren Harkness Everett, instructor in embryology. The clinical assistants this year will be: Harry Seymour Pearse, William Henry George, Michael Daniel Stevenson, Washington Irving Goewey, Robert Hill Tedford, Jr., Fred Newman Guyer.

New York City.

The announcement two weeks ago that the New York School of Clinical Medicine was permanently closed, was evidently founded on a false report. The school is still open.

CORNELL MEDICAL COLLEGE.

The new building of this college is nearly complete. It has cost, including the site, more than $600,000, all of which has been furnished by Col. Oliver H. Payne, who has also created a large endowment fund.

INFANT MORTALITY.

More bodies of children were received at the Bellevue morgue on July 17 than on any day since its institution. At midnight on that date the bodies of 33 children of 5 years old and under had been received, 11 of which were sent from private houses and 22 from hospitals.

MARYLAND.

Dr. Abraham Claude, Annapolis, recently celebrated his golden wedding anniversary.

Dr. Guy Steele has been appointed health officer for the city of Cambridge and Dorchester County.

The local registrars of vital statistics in the counties, of whom there are several in each county, under the act of 1900, receive a fee of 20 cents for each full record and return. Payment is made only on certification by the state registrar that the certificates are in fact duly executed and returned.

Baltimore.

Dr. T. C. Gilchrist sailed for Paris, July 21.

Dr. John J. Caldwell has been appointed editor of *The Medicus.*

Dr. William Lee Howard is cruising along the Atlantic Coast in his sloop yacht *Kelpie*. He will go as far east as Halifax.

Prof. R. Dorsey Coale has been elected dean of the University of Maryland School of Medicine, vice Dr. Charles W. Mitchell, resigned.

DR. WILLIAM HALSTED.

Dr. William S. Halsted, who has been elected to honorary fellowship in the Royal College of Surgeons of England, is a native of New York City, and is 48 years old. He took his A.B. at Yale in 1874, and M.D. at Columbia College, N. Y., in 1877. He served as demonstrator of anatomy in his alma mater, and assisted in Bellevue, Roosevelt, Presbyterian and other hospitals in New York. On the opening of the Johns Hopkins Hospital he began work in Professor Welch's laboratory, and in 1893 he was made chief surgeon of the hospital and professor of surgery in the University.

CALIFORNIA.

LANE MEDICAL LECTURES.

The fifth course of the Lane Medical Lectures, inaugurated in Cooper Medical College in 1896, will be given in 1900 by Sir Michael Foster, K.C.B., M.P., Professor of Physiology, University of Cambridge, England. These lectures will be given on the days and hours, as follows: August 20, 11 a.m., Vesalius, his forerunners and followers; the beginning of modern physiology. August 20, 8 p.m., Harvey, and the circulation of the blood; the lacteals and lymphatics. August 21, 11 a.m., Borelli and the influence of the new physics. August 21, 8 p.m., Malpighi and the physiology of glands and tissues. August 22, 11 a.m., van Helmont and the rise of chemical physiology. August 22, 8 p.m., the physiology of Sylvius and his pupils; digestion in the Seventeenth Century. August 23, 11 a.m., the English School; the physiology of respiration in the Seventeenth Century. August 23, 8 p.m., Priestly and Lavoisier; the modern doctrines of respiration. August 24, 11 a.m., Réaumur and Spallanzani; the physiology of digestion in the Eighteenth Century. August 24, 8 p.m., Haller and the physiology of the nervous system.

MISSOURI.

DR. EDWIN E. HUNTER, St. Joseph, has been appointed assistant city physician.

THE *Medical Review* begins the new volume with a slight change in its title. Hereafter it is to be known as the *St. Louis Medical Review*.

SEVERAL ADDITIONS have been made to the faculty of the College of Physicians and Surgeons in Kansas City. Herman E. Pease will have the chair of gynecology; Howard Hill, surgical anatomy; A. M. Wilson, physiology; Joseph B. Connell, dermatology; George Boyd, bacteriology and pathology.

MICHIGAN.

DR. H. M. GALE, Bay City, has returned from Europe.

THE MICHIGAN State Medical Society, at its last meeting, appointed Dr. E. Amberg, Detroit, to represent it on the Committee on National Legislation of THE AMERICAN MEDICAL ASSOCIATION.

THE BOARDS of the four state insane asylums met in Traverse City, July 19. A committee was appointed to revise the asylum laws; and if deemed advisable, the revision will be introduced as a bill in the next legislature.

VERMONT.

THE MEDICAL board of St. Albans met July 18 for the election of officers. The result was as follows: president, J. N. Jeune; vice-president, Allan Davidson; secretary, C. P. Lunderville; executive committee, J. N. Jeune, C. C. Berkley, A. A. Skeels.

DR. GEORGE ANDERSON has resigned his position as house surgeon at the Mary Fletcher Hospital in Burlington, and has gone to Pittsford, where he will practice. Dr. C. A. Pease has been appointed to succeed him, and Dr. F. T. Jackson will succeed Dr. Pease.

OHIO.

THE WILL of Dr. Chas. Judkins, who died in Cincinnati, July 1, has been filed for probate. The estate is valued at $100,000, the use of which is left his wife her lifetime. At her death $40,00 will be used to establish an academy of medicine in Cincinnati, and the rest will be divided among the heirs.

IOWA.

DR. DAVID MCDILL, Burlington, has been appointed physician for the federal penitentiary of Kansas.

THE KEOKUK Medical College has added a department of pharmacy, that will be opened this fall.

CANADA.

MOSQUITO SPECIMENS.

A number of Canadian entomologists are busily engaged collecting mosquitoes, with a view to submitting reports to the Naturalists' Club. They are at present prosecuting their researches in Antigonish County, N. S., and one has already upward of eighty specimens captured in various parts of that district within the last two months. He states that there are already known to be fifty varieties, differing in appearances, habits and seasons for work. There the mosquito apparently thrives but malaria is unknown.

MARITIME MEDICAL ASSOCIATION.

(Concluding Report.)

The question of Dominion Registration was debated at the second day's proceedings of the Association. Dr. McNeil, of Prince Edward Island, a past-president of the Association, wrote asking that the meeting indorse the proposition unanimously. Speaking on the matter, Dr. Farrell, of Halifax, said that they had to look at the matter of inter-provincial registration as it stood. Dr. Roddick's bill in parliament had never yet seen the light in that assembly. Whether it would become law he could not say. The medical councils of the different provinces had never yet met in council on the matter. It would be easy for these councils to take up the matter, as it came legitimately under their control and they had funds for such purposes. Dr. Armstrong, Montreal, who was present at the meeting, said he understood from Dr. Roddick that he had thought it wiser to wait another year before pushing his bill. Dr. Farrell, seconded by Dr. S. Jenkins, of Charlottetown, then presented this resolution: "That this meeting desires to express its sense of obligation to Dr. Roddick for his unceasing efforts to obtain Dominion registration and to assure him of the continued support of The Maritime Medical Association." The following officers were elected: president, Dr. W. S. Muir, Truro, N. S.; vice-president for Nova Scotia, Dr. Thomas Trenaman, Halifax; vice-president for Prince Edward Island, Dr. Ross; vice-president for New Brunswick, Dr. Inches; Dr. G. M. Campbell, secretary; Dr. T. D. Walker, St. John, N. B., treasurer; local committee, Drs. Farrell, Wickwire, Curry, Kirkpatrick, Tobin and C. D. Murray, Halifax. Next place of meeting, Halifax.

Toronto.

A TORONTO physician has designed the latest development of the electromobile. It is a self-propelled invalid's chair, and has a capacity for a fifteen-mile run at the rate of four and one-half miles per hour.

CHANGES IN MEDICAL FACULTY, TORONTO UNIVERSITY.

The Senate of Toronto University has ruled that there shall be an examination at the end of the third year hereafter, in the medical course, and has also recommended the following changes, promotions and appointments on the staff: Dr. J. A. Amyot, to be associate professor in pathology and bacteriology, or professor of clinical pathology at his option; Dr. F. N. G. Starr, associate professor of clinical surgery and also demonstrator of anatomy; Dr. Walter McKeown, B.A., demonstrator of clinical surgery; Dr. Clarence L. Starr, demonstrator of clinical surgery instead of assistant demonstrator of anatomy. A. R. Gordon, M.B., demonstrator in clinical medicine instead of assistant demonstrator of anatomy; Dr. R. D. Rudolf, lecturer in medicine and clinical medicine, instead of assistant demonstrator of anatomy; Dr. K. C. McIlwraith, demonstrator of obstetrics, instead of assistant demonstrator of anatomy; Dr. W. P. Caven, associate demonstrator of clinical medicine; Dr. Alexander McPherson to be professor of medicine and of clinical medicine, in the place of the late James E. Graham; Dr. H. T. Machell, associate professor of obstetrics and pediatrics, his work to be confined to pediatrics; Dr. Graham Chambers, M.A., demonstrator of clinical medicine; Dr. G. R. McDonagh, professor of laryngology and rhinology; W. H. Ellis, M.A., M.B., professor of toxicology; Bertram Spencer, M.B. professor of medical jurisprudence; and Dr. W. H. Beemer, superintendent of the Mimico Asylum for the Insane, to be extra-mural professor of mental diseases.

JUDGMENT RE CONSUMPTION SANITARIUM SUIT.

This morning the magistrate rendered judgment in the case of Dr. Edward Playter, who is the proprietor of the consumption sanitarium at "Highfields," Moore Park, North Toronto. The charge against Dr. Playter, entered by the health officer of the township in which his institution was situated, was that of conducting "a noxious and offensive business." The magistrate has decided that the defendant is the sole and only person responsible for the establishing of the institution, without having obtained the consent of the municipality. He further decided under Section 72 of the public health act that the doctor was carrying on an offensive and noxious business, his establishment in no way being a sanitarium or a hospital. What few patients had availed themselves of the advantages of this so-called sanitarium were in the habit of lying along the streets, expectorating on the footpaths and sidewalks, and also into a large excavation on the back of the premises, without in the latter case, any effort being put forth to disinfect the contents. To this sort of thing the neighbors righteously objected; and on June 15 the Doctor was formally notified by the township health officer to remove his establishment to other quarters. Failing this, suit was brought to compel him to desist in his attempt to carry on a consumption sanitarium. The magistrate imposed the following fines: "I find the accused guilty of the offence charged and fine him $200 and costs, $21.50. He was notified to desist June 15, but, according to his own evidence, he had a patient there on July 25. For this he is fined $5.00 per day for each day, 40 days, or $200 additional." When distress is levied, if there be not sufficient to satisfy it, the Doctor, unless appeal be taken, must spend fourteen days in jail at hard labor. At the conclusion of his judgment, the magistrate remarked, that, "because of the strenuous opposition of the public, it would be useless to impose a nominal fine." The effect of the judgment in this case, which has been watched by the medical men of the city with no little interest, will no doubt have the effect of deterring others who may be similarly disposed from establishing such institutions without due and proper authority.

Montreal.

The exhibit sent to the Paris Exhibition by McGill University, for which a gold medal has been awarded, was composed of a magnificent series of mounted photographs, showing the exteriors of the university buildings, as well as the interiors of the most important lecture-rooms, laboratories, etc.

According to the mortality statistics, there was another very large death-rate in Montreal last week. The total deaths recorded reached 183. Infantile debility claimed 107; consumption and other chest diseases, 17; diphtheria, 3; scarlet-fever, 1; typhoid-fever, 3; measles, 1; whooping cough 3, and smallpox, 1.

Work is progressing on the additions to the medical faculty buildings for McGill, and a few of the new class-rooms will be ready for use in October. The old lecture amphitheater and the department devoted to pathology have been demolished entirely, and upon the sites they once occupied the new buildings are being erected. These improvements will cost $60,000.

INFANT MORTALITY.

The causes of the extraordinarily high death-rate at present prevailing among Montreal's children is causing the members of the Hygiene Committee keen concern and it is felt that something must be done to prevent this heavy death-rate among the innocents during the summer months. Out of a population of barely 300,000 it is truly appalling that in one week 116 deaths should be reported among infants, to be supplemented the next week by 107. The city health officer, Dr. Laberge, considers that the main causes for the death of these infants are the ignorance of mothers as to how properly to feed and take care of them; also overcrowding, want of fresh air, and, finally noxious privy pits in the city. A recently compiled mortality table shows that in the poorer wards of the city the death-rate is much heavier than in the western wards. A determined onslaught is to be made upon the privy pits, a source of great danger to infant life. Of these, in 1891 the city possessed 8528, whereas now they are 5201 in number. Alderman Ames, the chairman of the Hygiene Committee, has made a special study of sanitary matters of the city, and writing about these pits says that not 5 per cent. of them conform to the provisions of the by-law, which requires that they be water-tight. In the study which he made of this particular question three years ago, he was able to show that the death-rate and the prevalence of contagious diseases followed proportionately the number of privies in various localities. He is now fathering a measure before the city council which shall permit no privy pit to exist after May 1, 1900, without special permission granted by the Medical Health Officer. In this way will Montreal endeavor to get to the bottom of this harassing question.

Correspondence.

True Origin of the Epidemic of Yellow Fever.

New Orleans, La., July 21, 1900.

To the Editor:—"True Origin of the Epidemic of 1897 (Yellow Fever)", is the title of a well-written and very interesting article, in which Dr. J. H. White, of the United States Marine-Hospital Service, shows to his thorough satisfaction that yellow fever was introduced into Ocean Springs, Miss., in 1897, by a man named Thomas Shannahan.

Dr. White says (report of U. S. M.-H. Service for 1898, page 536):

> Thomas Shannahan came from Guatemala, where he spent a short time prior to sailing, at a hotel in Port Barrios, at which hotel yellow fever is said to have existed. He sailed from Port Barrios, on April 8, on the steamship *Breakwater* and arrived at quarantine at Port Eads on April 12, and the quarantine season not being at hand, he suffered neither detention nor disinfection of his effects. He arrived at Ocean Springs, Miss., on April 13, and was sick on arrival with chill and subsequent fever and great weakness. He went to his home, which is a hotel or boarding-house. In this house resided several small children who went to school in the village with the children of other families.

Dr. Walter Wyman, Surgeon-General U. S. Marine-Hospital Service, partly corrects this report in a subsequent statement, which reads as follows:

> In April, 1897, an American citizen, temporarily sojourning in Central America, determined to return to the United States. He was in San José, a small city on the Pacific Coast of Guatemala, one of those unsewered, insanitary Central American coast cities which are the breeding spots of yellow fever, where the disease prevails annually and is limited only by the amount of new material to feed on. He left in apparent good health, on or about April 6, and, partly on mule back and partly by rail, ascended the mountains and crossed over to the Atlantic Coast to Port Barrios, where he arrived April 7, and at once took a steamer for New Orleans.
>
> From the latter port he immediately proceeded to his home in Ocean Springs, Mississippi, where, on April 13, he was seized with an attack of yellow fever so mild as to escape observation. In due course of time, by the latter part of August, there was a well-defined epidemic of yellow fever in Ocean Springs, and it had spread to other states, with results which must still be fresh in the minds of all here present, of shotgun quarantines, disturbance of business, interruption of passenger traffic, hardships imposed on travelers, and all the other unhappy concomitants of a yellow-fever epidemic.
>
> The foregoing mortality, therefore, the interruption to traffic and travel, and the injury to the business of great commercial cities, almost incalculable in amount, during the last three years, can be traced to the conditions prevailing in the little town of San José, on the Pacific Coast of Guatemala.—"Our Sanitary Obligations," *Morning News*, of Savannah, Ga., March 22, 1900.

It is truly remarkable, and almost incredible, that men of such standing and of such undoubted ability, should utter so lightly these terrible statements.

Quite recently—July 5, 1900—Dr. Wyman has made a still further correction, as follows:

> . . . It should be noted, however, that one statement of this report (i. e., of Dr. White) is erroneous and was intended to be corrected before publication, viz., the statement that yellow fever existed at Port Barrios.
>
> It was intended to state that yellow fever existed at San José, whence this party crossed the isthmus and took ship at Port Barrios.

Dr. C. P. Wilkinson, resident physician of the Mississippi River Quarantine Station refutes these charges in the report of the Louisiana State Board of Health for 1898-1899. After quoting the paragraph from Dr. White's report relative to Shannahan's return from Gautemala, as above set forth, Dr. Wilkinson says:

> From the Shannahan hotel Surgeon White traces a case of what was diagnosed spinal meningitis by the attending physicians, April 22. From these two cases, Surgeon White attempts to trace connection with every other case of sickness in Ocean Springs. It is well to bear in mind that not one fact of these cases was in possession of Surgeon White, until some time in September of that year.

His house of cards will collapse if he can not trace any connection of Shannahan with yellow fever in Gautemala. A whole theory, a solution of a scientific problem, a guide to the conduct of a large commerce, and the protection of life and property is based on—*"said to have existed."* Authority for the statement is not quoted.

. . . .

It is not possible that infection, existing at Port Barrios, could be carried away to Ocean Springs, and at the latter place spread, and at the former instantly die out. Nor is it possible that Shannahan only would carry away infection, for there were others departed from the same hotel at Port Barrios, who went to other places, and who did not convey infection. Further than this, reliable testimony of the conditions prevailing at Port Barrios, in April, 1897, could have been obtained by Surgeon White in any investigation having the whole truth as its object, and this testimony would have absolutely convinced any intelligent person that Shannahan's connection with yellow fever in Guatemala was disproved. The following specific letter furnishes valuable testimony to contradict Surgeon White's assertion:

"January 1, 1900.

"Dr. C. P. Wilkinson, Resident Physician, Mississippi River Quarantine Station: *Dear Sir:*—On April 20, 1897, I visited Port Barrios, Guatemala, visiting the hotel at that small place. While I was not on any official mission, I did not neglect to avail myself of the opportunity of inquiring into the health status of the various ports in British and Spanish Honduras and Guatemala, which I visited at that time. The statement that yellow fever existed at the hotel in Port Barrios, about April 8, 1897, is untrue. To my knowledge there was none at the time of my visit, April 20, 1897; nor was there any rumor or report or suspicion of such disease at any time previously. At the time of my visit, I personally met Dr. Kilgore, the surgeon in charge of the railroad hospital at Port Barrios, who was in a position to know, and did know exactly the health condition of Port Barrios, who stated to me that the port and the vicinity were absolutely free from any infecious disease whatever. This statetment was corroborated by Dr. Odeneal, chief surgeon of the Guatemala Northern Railroad; by Dr. French, surgeon on the line, and other reputable persons in Port Barrios and Livingston. It is claimed by the residents of Port Barrios that there never has been any yellow fever at that place, which claim, after having given the subject some attention, I am convinced can be substantiated.

"John N. Thomas, M.D., Quarantine Inspector."

I have also a certificate from Dr. Kilgore that Thomas Shannahan was just prior to his departure from Port Barrios a section foreman of the railroad running into that place, and that Shannahan was a victim of paroxysms of malarial fever.

The report of Dr. Mark Finney, the resident medical inspector at Port Barrios and Livingston, for the Louisiana State Board of Health, beginning his duties on April 15, 1897, certify that no contagious diseases, or rumors, or suspicions of such existed in Port Barrios, or anywhere in that vicinity. The Marine Hospital records show, by reports from United States consuls in Guatemala, that the government of that country, in the early summer of 1897, forbade the entry into its ports of vessels from the yellow-fever-infected port of Panama, and used every endeavor successfully to prevent introduction of that disease into any of its ports. In the face of all this evidence it is past the bounds of credence to ask any one to believe that there was any yellow-fever infection in Guatemala for Shannahan to take away with him.

Further on in Surgeon White's report he says:

"Mrs. Gonzales, I understand, was frequently at the Shannahan house to see Cuban sympathizers stopping there."

This statement opens up a very interesting line of investigation. Was the Shannahan house infected by persons from Cuba? Who were these Cuban sympathizers ? Whence did they come, and when, and how?

Early in 1897 it was difficult for persons to leave Cuba if there was any good reason for the Spanish authorities to believe they were sympathizers with the Cuban cause. It was possible for some to slip away clandestinely from the island and get on board vessels bound for the United States. This procedure involved a certain irregularity on the part of the master of that vessel, which irregularity it was hard for him to explain when coming before the authorities of the United States quarantine and custom-house. Evasion of this necessary explanation could be secured, however, if his living freight, their goods and chattels, could be as clandestinely debarked as they were embarked, and this evasion was easy of accomplishment along the Mississippi Sound coast, coming in under cover of darkness, to the east or the west of Ship Island. That this clandestine practice has been resortetd to at times, I learned in three instances: once the debarkation of passengers at the Rigolets, bound for New Orleans, once the debarkation of passengers near Pass Christian, and once on the Florida coast. My informants were masters of schooners trading between Havana and the Mississippi Sound, who stated they had done these things, and also informed me it was not so very unusual for others to do them.

I do not think it at all improbable that clandestine communication between Havana and Shannahan's house was established early in 1897, and this communication without any of the formalities of quarantine. The motives for this communication existed; it was easy of accomplishment; it had been done before; was it done in this instance, and did some other person than Shannahan bring infection to the Shannahan house?

Bearing on this subject, I present the following letter from Mr. J. M. Leveque, of New Orleans:

"New Orleans, La., January 1, 1900.

"Dr. C. P. Wilkinson: *Dear Sir:*—Early in 1897, as reporter for the New Orleans *Picayune,* I was detailed to gather such items as I could regarding the movements of Cuban sympathizers here and along the Mississippi Sound coast. It is within my knowledge that Ocean Springs, Miss., was their headquarters; and their usual meeting point a house, owned by Mrs. Gonzales, at that place. I also know that expeditions of a secret character came to and went from Ocean Springs, and I have it on the authority of parties in the heart of the movements that these expeditions communicated directly with Havana and other ports on the Island of Cuba. These expeditions, I know, were composed of quite a number of persons, who carried out and brought back many articles of contraband and personal effects, and, of course, with careful avoidance of either quarantine or custom-house. About the middle of March, 1897, certainly not later than near the close of that month, Mrs. Gonzales told me there was a person ill at her house in Ocean Springs with what she was positive was yellow fever. I asked her if she was not mistaken, that thus early in the season yellow fever was unheard of in this country? She said that she had become so familiar with the disease during her long residence in Cuba she could not possibly be mistaken. I gave the matter little thought at the time; the appearance of the disease so early in the season being so improbable; and long absence of the disease from our country to me entirely precluded any apprehensions of evil. Of course, Mrs. Gonzales remained silent for other reasons. Long afterward, when the disease spread and became publicly known, Mrs. Gonzales recalled to me that her diagnosis had been correct, and I am now positive that yellow fever was brought to Ocean Springs, Miss., by the Cuban with their effects, operating from that point. "J. M. Leveque."

It was not denied that the point for greatest distribution of yellow fever in Ocean Springs, in 1897, was the Shannahan hotel. I have been at some pains to gather specific information regarding the probable infection of that place. I present the testimony given to me by persons of the highest character, and I name them. I do not think it can be denied that the infection of Ocean Springs did not come from Guatemala through New Orleans, or that it did come from Cuba through evasions of the quarantine station at Ship Island.

C. P. Wilkinson, M.D., Resident Physician.

But the most remarkable part of the whole affair is that no one seems to have sought for the truth at the fountain-head, that is, from the man Shannahan himself.

I was struck with this serious and very remarkable omission and instructed Dr. Horton, medical inspector of the Louisiana State Board of Health, to find Shannahan and get his statement of the facts. This statement, in the form of an affidavit, is here appended. It speaks for itself.

New Orleans, July 7, 1900.

Parish of Orleans, State of Louisiana, *ss.*

Before me, Felix J. Dreyfous, a Notary Public, in and for the Parish and State aforesaid, personally appeared Thomas B. Shannahan, who, upon being duly sworn, deposed and said: That he was born at Ocean Springs, Miss., in 1874; that he went to Guatemala late in the summer of 1895 and remained there continuously until April 1897, with the exception of one trip which he made to Belize, British Honduras, in 1895.

That during the time of his residence in Guatemala he was employed as a mechanic in the service of the Ferrocarril del Norte. (Railroad projected from Puerto Barrios to Guatemala City.)

That he was never at any time in San José or any other seaport on the Pacific Coast, having gone no further from the east coast than the town of Zacapa, about 135 miles from Puerto Barrios, between which point and Gualan, a station on the railroad some fifty miles east of Zacapa, affiant worked.

That during his entire residence in Guatemala he suffered more or less with malarial fever, for which he was treated at different times by Dr. Kilgore, at Puerto Barrios, and Dr. Odeneal, the railroad surgeon, at Zacapa.

That he never heard of any yellow fever at Zacapa, Gualan or Puerto Barrios or at any other point on the railroad.

That, on the occasion of his return to the United States he left Zacapa in the morning and arrived at Puerto Barrios the same evening; that he did not stop at any hotel in Puerto Barrios, but slept at a house occupied by his brother.

That his brother was not then ill, and to the best of affiant's knowledge had not been ill at any previous time. That there were no other occupants in that house besides affiant's brother.

That affiant and his brother sailed the next morning for New Orleans; that on the voyage affiant was sea-sick, but not otherwise ill.

That the steamship arrived at the wharf in New Orleans after night; that affiant and his brother slept on board, and the next day took an evening train to Ocean Springs, arriving there the same night; that he had a chill the next day. Dr. Robinson, a physician from Edwardsville, Ill., temporarily sojourning at Ocean Springs, first prescribed for affiant; later Dr. Bragg, a local physician, attended him.

Affiant further deposes that he was not continuously ill, but would have a chill and fever lasting a few hours, after which he would get up and go about until the next chill, usually on the third or fourth day.

Further that he continued to have these intermittent attacks from time to time during the entire summer of 1897.

[Signed.] T. B. SHANNAHAN.

Sworn to and subscribed before me this 7th of July, 1900.

FELIX J. DREYFOUS, Notary Public.

It thus appears that this man had never been in San José nor at any place where there was yellow fever, prior to arriving at Ocean Springs, and the whole structure falls to the ground like the "House of Cards" that it is.

EDMOND SOUCHON, M.D.,
President Louisiana State Board of Health.

Death During Use of Schleich Solution.

OMAHA, NEB., July 22, 1900.

To the Editor:—Since Dr. Willy Meyer called the attention of the American profession to the Schleich solution in 1897, I have been a careful student of its use and have had opportunity for my studies in my work as anesthetist of the Presbyterian Hospital and while giving it, upon invitation, in the Presbyterian Hospital in Chicago for Dr. Etheridge, Dr. Stehman and Dr. Hamilton, in Mercy Hospital for Dr. Murphy, in the Dental College for Dr. Brophy, and in Cook County Hospital for Dr. Burton, and in my own city for many of our surgeons.

I have been deeply impressed with its qualities, its superiority and its comparative safety. I have never felt that it was a safe anesthetic, for we have none, nor can we ever have one. It becomes my duty to report a death from its use, and it is the first one of which I have known in America.

The patient was Miss H., a young woman of 23; fairly robust, well nourished, heart-sounds fairly clear and distinct, no valvular lesion; she was to be operated upon for recurrent appendicitis, having recently recovered from her second attack; upon beginning the anesthesia, I held the Stone mask —a metal mask, rubber tired, an opening on top of seven-eighths of an inch in diameter—two inches from her face, and was three minutes in getting the mask down upon her face; she took the solution kindly and in six minutes had corneal anesthesia, and, in two more, surgical anesthesia. She was then carried into the operating-room and made ready. After about three minutes of preparation, she was relaxed; the pupils were very small; the lower jaw was dropped. I announced to the surgeon that she was ready. She barely flinched when he made the incision, but more when he separated the muscles. I saw this and endeavored to make the anesthesia more profound by dropping the solution on more rapidly. The reflex due to the incision and separation of the muscles had not caused the pupils to widen *at all*, for I was watching them most carefully. It merely caused her to move a little. Her face was of good color; her pulse was good; the surgeon had removed the appendix, when the following sequence of events took place:

The pulse became weak; then irregular; then intermittent; then it ceased; the respiration, which had been regular and normal, became very rapid; this for six or eight respirations only; while the pulse was failing, before it had ceased, the pupils were still very small; instantly they dilated widely and death took place. With the first sign of trouble, I had removed the mask; the face was then pallid.

The usual measures for restoration: strychnia, rhythmic traction of the tongue, artificial respiration, etc., were carried out for sixty minutes, without eliciting a sign of life.

Death was due to paralysis of the heart center, followed by paralysis of the respiratory center.

I have now given the Schleich solution 441 times and this experience covers most of the major operations. The usual experience is that the patient goes quietly to sleep with no excitement whatever; nausea was present in the last fifty cases, during anesthesia, eight times; three of these had fairly severe nausea; five had nausea but once.

Only six vomited after recovery from the anesthetic. Serious conditions developed in thirteen cases of the 441. Two had great dread of the anesthesia from prior experience with chloroform; one had a mitral lesion; three had a markedly feeble heart; two were chronic alcholics; but three of the thirteen were those in whom one had not a right to expect trouble.

With this unfavorable experience, I still feel that the Schleich solution as an anesthetic is of greater value and of less danger than is either one of the others.

R. M. STONE, M.D.

Book Notices.

CANCER OF THE UTERUS, ITS PATHOLOGY, SYMPTOMATOLOGY, AND TREATMENT; ALSO THE PATHOLOGY OF DISEASES OF THE ENDOMETRIUM. By Thomas Stephen Cullen, M. B. (Toronto), Associate Professor of Gynecology in the Johns Hopkins University. With eleven Lithographic Plates and over three hundred colored and black illustrations in the text, by Max Brödel and Hermann Becker. New York: D. Appleton & Co. 1900.

This is a superb volume from the view-point of the maker of medical books, excellently, profusely, and always instructively illustrated. The artistic drawings of Brödel and Becker have been reproduced with uniform success. The illustrations of gross anatomy are from Kelly's "Operative Gynecology"; a small number of figures are taken from other publications from the gynecological clinic of the Johns Hopkins Hospital, the large majority being original. The figures showing the development and the structure of the various forms of carcinoma of the uterus are especially instructive and faithful reproductions. No less so are the illustrations of the numerous conditions and processes—including practically the whole range of uterine pathologic histology that may be confounded with carcinoma. The large fields, the insertion of drawings of many of the gross specimens from which the sections were made, and the clear and full explanations are of great help in getting a clear idea of the subjects presented. The volume contains 693 pages. There are 27 chapters and a short appendix.

It is largely an original work and represents a critical and telling study of the clinical and anatomical material from Dr. Kelly's service. The text is never overburdened with citations from the literature, which is utilized only to fill up gaps not clearly illustrated by original cases. It is not often that the author is forced to rely wholly on the work of others. At the same time he has carefully covered the literature in his reading so that he is always in direct touch with current fact and opinion. Cancerous growths of the uterus are divided into four groups: 1, squamous-celled carcinoma of the cervix; 2, adenocarcinoma of the cervix; 3, adenocarcinoma of the body; 4, squamous-celled carcinoma of the body (rare). This is a simple, yet sufficiently comprehensive classification; and the reader is not confused at the very outset by a parade of the many varieties described by different authors.

The gross anatomy of the uterus and the histology of the uterine mucosa are carefully described. A clear knowledge of fundamental facts of this character is essential in order to understand the origin, the structure, and the extension of uterine carcinoma. The operation of scraping the uterus and the methods of examination of tissues for diagnostic purposes are detailed. This chapter contains many points of great value to the practical pathologist. The author's technique of making frozen sections makes it possible to reach a diagnosis in fifteen minutes or even less, so that in certain cases the radical operation may be made forthwith. One may well understand the author's thankfulness to his associates for their consideration in refraining from mutilating the specimen obtained by operation—a harmful custom in vogue at many clinics, often preventing the preservation of finer structures. The technique of examination of the uterus after removal is outlined fully.

During a period of less than six years 182 cases of carcinoma of the uterus came under observation; of these 128 were squamous-celled carcinoma of the cervix; 19 were adenocarcinomas of the cervix, and 35 adenocarcinomas of the body. Squamous carcinoma of the cervix is numerically the most important form, and 239 pages (Chapters iv-viii) are given to its consideration. From the study of the early stages of this form it is shown that it is due to an ingrowth and branching of the squamous epithelium of the part coincident with a branching outgrowth of stroma and epithelium in the form of finger-like processes. This stage is followed by more or less disintegration of the cervix. The extension to neighboring structures, the formation of lymphatic and other metastases, and the development of complicating lesions of inflammatory and obstructive nature are described. The many points of major as well as minor importance are made interestingly clear by the thorough study of individual cases accompanied with numerous figures.

The clinical aspects are then considered. It is shown that here, as well as in the other forms of uterine carcinoma, "the diagnostic symptoms at best are meager, and in the early stages give little or no clue to the real nature of the disease. Hence the value of curettage when there is the slightest uterine hemorrhage that can not be satisfactorily explained." The clinical and histological, differential diagnosis of squamous carcinoma of the cervix is fully considered. All the various conditions that may be mistaken for carcinoma are considered seriatim.

In the chapters on treatment all the measures that have been suggested and employed are not given, but only those that have been found most satisfactory at the Johns Hopkins Hospital. The development of the various steps in the operative technique—ureteral catheterization, removal of iliac glands, etc. —are sketched. To Ries is given the credit for recommending the systematic removal of the lymphatic glands, and Pawlik is given the credit of introducing ureteral catheterization in hysterectomy. Werder's operation "appears to be the most promising one, allowing as it does, such a wide removal of the vaginal mucosa with its underlying connective tissue." A wide field is predicted for this operation. The various steps in the operative procedures are clearly and fully illustrated. Not the least interesting part in the chapters on treatment is the open and unreserved statement of all the accidents and mistakes happening to the operators at the Johns Hopkins Hospital.

Chapters ix-xii deal with adenocarcinoma of the cervix. In this book adenoma does not even designate a benign tumor, and adenocarcinoma "indicates a glandular growth, which runs rampant, invading the tissue in all directions." All phases of this form of carcinoma are presented with great completeness. This is also true of adenocarcinoma of the body of the uterus (Chapters xii-xix). A valuable feature of these chapters is the careful descriptions and the illustrations of the uterine scrapings, from the appearances of which the diagnosis was made in many of the cases. Throughout the book the objective character of the statements and of the whole manner of presentation can not fail to impress the reader. In adenocarcinoma of the body, the question of lymphatic metastasis is of little practical importance, because it has been found that in operable cases lymphatic invasion has not had time to develop. The reason for the late development of metastasis is to be found probably in the large size of the tumor cells. The chapter (xv) on other processes associated with adenocarcinoma is full of valuable practical suggestions. And in Chapter xvii, on the differential diagnosis in adenocarcinoma of the body of the uterus, all the clinical and pathologic material of the hospital for the last seven years has been utilized, and every condition that may be confused with adenocarcinoma is dealt with. This chapter is very valuable. Operation for carcinoma of the body of the uterus gives brilliant results, provided the diagnosis is made early. Nearly every disease of the endometrium is marshalled before the reader in word and picture with a view to render the diagnosis of obscure cases of carcinoma more frequent.

Primary squamous-celled carcinoma of the body of the uterus is rare; only three cases are authentically described; no such case has come under Cullen's personal observation.

In Chapter xx an instance of a rare form of adenocarcinoma of the uterus is described. Chapter xxii contains a full summary of our knowledge of deciduoma malignum, based largely on the articles of Williams and Dorland. Chapter xxiii discusses pregnancy complicating carcinoma of the cervix; C. xxiv the clinical phenomena common to all forms of uterine carcinoma; and C. xxv the prognosis. Inasmuch as the cases studied date back only six or seven years, the question of the number of permanent cures is set aside. The general summary shows that in 123 cases of squamous-celled carcinoma 62 came too late for operation; of the 61 operative cases 13—20 per cent.—were well Jan. 1, 1900. Of 18 cases of adenocarcinoma of the cervix 6 came too late for operation and 2—16 per cent. —were alive on the above date. Of 35 cases of adenocarcinoma of the body 5 came too late, 20—66 per cent.—are now living. This shows, in the first place, the large percentage of patients that are deprived of the possible benefits of operation until it is too late, and secondly, that the prognosis is best in adenocarcinoma of the body. Dr. Cullen, we are glad to say, belongs to those who "are content to operate, provided there is the slightest possibility of saving the patient." In this he evidently reflects the spirit of his chief.

In Chapter xxvi, devoted to the etiology of carcinoma, Cullen considers the various theories in vogue in their application to carcinoma of the uterus. The conclusion is inevitable that "the injuries incidental to labor have a potent influence" in the development of squamous-celled carcinoma of the cervix. There is no evidence in the support of the theory of an embyronic origin of uterine cancer; the histologic pictures all go against Ribbert's theory and favor the view that carcinoma is primarily a disease of the epithelium. Chapter xxvii discusses briefly experimental inoculation of carcinoma and the accidental implantation of carcinoma into healthy tissue during vaginal hysterectomy. The evidence indicates that implantation may occur and that the chance of conveying carcinoma particles into healthy parts should be avoided by all means.

The book ends with an appendix containing J. Knowsley Thornton's plea for the early diagnosis of malignant disease of the uterus. It is the general practitioner who is first consulted, as a rule, and on him largely rests the responsibility of reaching a timely diagnosis. It is universally known that the number of cases of uterine carcinoma allowed to run along until too late for operation is appalling. Ways and means must be devised by which the dread disease may be detected at the earliest moment possible. It has been Dr. Cullen's aim to give the family physician a clear idea of the early signs of carcinoma, in order that he may always be on his guard, and may not treat too lightly any suspicious indications which may be present. That Cullen has achieved an unqualified success is absolutely certain. Even the skilled gynecologist and pathologist will derive much help and encouragement from this book. Written in a clear and attractive style, admirably arranged, and permeated throughout by a practical yet scientific spirit, we venture the opinion that few medical books make as interesting reading. The book is remarkably free from irrelevant material and from omissions. Throughout there is the closest correlation between the clinical picture and were also reported. The Society adjourned to meet at Millville the second Tuesday in October.

German Congress of Naturalists and Physicians.—The seventy-second annual congress will be held at Aachen, from September 17 to 21. Verworn and Nissl will describe the present status of the "Neuron Theory," Chiari, "Pathologic Anatomy in Connection with External Medicine," and Naunyn, "Internal Medicine." An exhibit of preparations and appliances is also announced. Three hundred communications have been already received.

American Association of Obstetricians and Gynecologists.—This Association will hold its thirteenth annual meeting in Louisville, Ky., Sept. 18, 19, and 20, 1900, under the presidency of Dr. Rufus Bartlett Hall, of Cincinnati. The following titles of papers have already been received: President's address, R. B. Hall; ovarian fibroma—case with microscopical report—L. H. Laidley, St. Louis; cholelithiasis—with report of cases—H. E. Hayd, Buffalo; appendicitis during pregnancy, Charles G. Cumston, Boston; diagnosis of ectopic pregnancy before rupture, based on ten cases, J. F. Baldwin, Columbus; three cases of extrauterine pregnancy, with specimens, W. B. Dorsett, St. Louis; the private hospital, Joseph Price, Philadelphia; extirpation of the rectum and sigmoid per vaginam, John B. Murphy, Chicago; the hymen—of what significance is its presence or absence in determining virginity? John Milton Duff, Pittsburg; a satisfactory method for suspension of the uterus, Robert T. Morris, New York; some points regarding surgery of the gall-bladder, A. Vander Veer, Albany; surgery of the liver and bile-ducts, W. G. Macdonald, Albany; observations respecting malignant disease of pelvic organs, Augustus P. Clarke, Cambridge; bilateral celiotomy and shortening of the uterus, A. Goldspohn, Chicago; round ligament ventrosuspension of the uterus, D. Tod Gilliam, Columbus.

Third District Branch of the New York State Medical Association.

Binghamton, N. Y., June 21, 1900.

President J. M. Farrington, Binghamton, in the chair.

BROTHERHOOD OF THE MEDICAL PROFESSION.

Dr. J. M. Farrington, Binghamton, delivered the annual address, taking the above as his subject.

In the early years of one's medical career one particularly feels the need of the beneficent influence of a true medical brotherhood. As far as can be conscientiously done the mantle of charity should be thrown over the faults of professional brethren. After long years of patient and persistent obedience to the Code of Ethics he had learned how good and pleasant it is for men to dwell together in unity. He urged with the greatest earnestness, a firmer brotherhood among physicians, showing this not only by helping brethren when avaricious people desire to rob them of their just remuneration but by sympathy and friendly administrations in time of trouble and affliction. He felt confident that each one would work out for himself the most practical method of promoting this feeling of brotherhood.

INDIGESTION AND BILIOUSNESS.

Dr. J. H. Martin, Binghamton, in this paper, said that in the digestion of albumins the process should begin in the mouth with mastication. When the resulting process, albuminose, reaches the duodenum, it is transformed into peptone. Fatty substances are not acted upon in the mouth except that the fatty envelope is broken up. Good teeth, a healthy stomach, plenty of hydrochloric acid and pepsin are requisite for proper digestion of albuminoids. Sad intelligence, fright, marked emotions, all interfere seriously with gastric digestion. Nervous disturbance sometimes causes a too rapid passage of the food into the intestine, with resulting diarrhea and the passage of undigested food from the bowel. Where the patient suffers from epigastric discomfort, and yet rises from the table with the appetite unsatisfied, the underlying condition is usually an excess of hydrochloric acid. In treating indigestion, the first thing is to determine whether the albuminoids or the hydrocarbons are at fault. In one case of exceptionally feeble gastric digestion under the author's observation, the patient was kept on a diet of boiled rice for five years, with the result that normal digestion was restored. This was, of course, an extreme case and ordinarily it is not necessary to persevere so long with such a restricted diet. There is a decided excess of indican often in the urine where much fermentation is going on in the intestine. Such an excess of indican often indicates not only intestinal fermentation, but carcinoma of the stomach. For ordinary gastric flatulence he had never found anything act more satisfactorily than a mixture containing resorcin, peppermint water and simple elixir. Biliousness was defined as a form of indigestion occurring in persons who eat meat very freely, and whose livers have been overworked. If, for some reason, the liver is unable to break up the nitrogenous portion of the food into the soluble constituent of the urine—urea—there is formed uric acid, or urates. With this excess of uric acid and urates come the numerous symptoms of lithemia and functional nervous disorders. In the so-called cases of "torpid liver" there is, in addition to coated tongue, a bitter taste in the mouth, yellowish conjunctiva, and other familiar symptoms. The patient is apt to complain of feeling intensely drowsy after eating. The indications are to clear out the alimentary canal and administer a mercurial or that much-despised but very excellent cholagogue, sulphate of soda. The diet should be, of course, suitably restricted.

Dr. Frederick Holme Wiggin, New York, said he had noticed for some time that in cases of chronic intestinal obstruction from any cause there was very apt to be a glazed and swollen tongue. He supposed it was produced by the depraved state of the blood resulting in a condition allied to scurvy. He had recently had a case of benign tumor of the cecum in which there had been in addition, swollen gums, and ecchymotic spots on the skin. He had removed the cecum and tumor, and afterward the occurrence of hemorrhages from the vagina had still further emphasized the depraved and scurvy-like condition.

Dr. Marvin said that before he had paid so much attention to disturbance of the digestive organs he recalled the case of an old lady whose tongue had presented this peculiar glazed condition. Without really knowing why, he had given her the old tincture of iron, and it had acted most satisfactorily. It was ascertained subsequently that she was suffering from carcinoma of the stomach, and then it had occurred to him that the explanation of the beneficial action was to be found in the absence of hydrochloric acid in the stomach and the filling of this deficiency by the hydrochloric acid in the tincture of the chlorid of iron.

CEREBRAL SYPHILIS.

Dr. L. P. Blair, McDonough, said that cerebral syphilis made its appearance in the secondary and tertiary stages of the disease, and at a period of from one to twenty years from the time of the original infection. In one case in his practice the cerebral symptoms had developed promptly after the healing of old varicose ulcers of the leg. The prodromal symptoms of severe and localized headache, worse at night, with pain increased on pressure; insomnia without well-defined cause; sensations of numbness in the extremities; great irritability of temper, all point to this condition, but the diagnosis of cerebral syphilis is often extremely difficult, and often is made only by the good results from antisyphilitic treatment. Extreme tenderness over the dorso-lumbar spine never had been found absent in these cases of severe cerebral disease. While all admit that mercury and potassium iodid are the only remedies which can be relied upon, their administration is often rendered very difficult by the intolerance of the stomach, especially to iodids. The latter are given ordinarily by the mouth, but he has recently administered them in nutrient enemata to a person who could not swallow, and with the best results. The patient at the time was thought to be moribund; consciousness was lost; the limbs were in a state of tonic contraction, and the temperature was subnormal. Thirty grains of potassium iodid were given in a pint of beef peptonoids by the rectum every three hours. He was requested to see the man again three days later, and, to his surprise, found him conscious and greatly improved in every way. He admitted having contracted syphilis about ten years previously, and having had treatment for about one year. The iodids were increased, and were given by the rectum most of the time until he fully recovered, about four months afterward. An attempt was made to give the iodids by the mouth, but this caused so much gastric disturbance that the administration per rectum was resumed.

Dr. **Elias Lester**, Seneca Falls, said that where there was a distinct history of syphilis the treatment outlined in the paper was, of course, eminently proper, but there were not infrequently cases in which no such history could be obtained, and the medical attendant learns of the true nature of the case *only after death of the patient.* A case was mentioned in which a well-known and respectable business man had suddenly lost consciousness in the street. He recovered promptly, but had another attack shortly afterward, diagnosed as cerebral apoplexy and hemiplegia. After his death the wife brought letters from a post surgeon in the army who had treated the man for syphilis years before, and urged the man to keep up his treatment. In the case just narrated there had not been the slightest suspicion of syphilis. His favorite treatment was the use of potassium iodid and injections of a mercurial cerate rather than the ordinary blue ointment.

Dr. **F. W. Higgins**, Cortland, said that he had tried antisyphilitic treatment in cases which he had supposed to be syphilitic lesions of the central nervous system, but without any success. After further study of the subject he had come to the conclusion that if the tertiary lesion is in the nerve substance proper, this treatment is of little value; but if there is pressure on the nerve truncs or centers, prompt relief is afforded by such medication. He did not know that this statement would be borne out by others, but it had been his experience. He believed the antisyphilitic treatment should be pushed when once begun, and that the iodid was of more importance than the mercury. It was not well to lay too much stress on the results of such treatment, as proving the syphilitic nature of a case. He had learned that where there was a hemorrhage there was apt to be an increased temperature. When there was sudden loss of consciousness and the temperature was not increased after a day or two, he would be suspicious of the presence of an embolus, or of some such lesion as had been indicated in the paper. If one could distinguish between a lesion in the brain and one pressing on the brain it would greatly influence both our prognosis and treatment.

Dr. **Williams**, Green, said that three or four years ago he presented a paper to the Chenango County Medical Association on "Subnormal Temperature in Disease." Mention was made of a patient who presented alarming symptoms, though thoroughly saturated with iodid. There was a history of continuous subnormal temperature. He had been under the author's care from the beginning. With the increase of pain the temperature was decidedly lower, often as much as four or five degrees below normal. In another case there was a history not only of syphilis, but of traumatism to the cervical ganglion. In this case, the exacerbations and remissions of pain were about twelve hours apart. During the height of the pain, which was excruciating, the temperature would drop to 95 F., and during the remission of pain the temperature would rise to within one or two degrees of normal. In the first case, after thorough saturation with iodid, this was abandoned, and the patient was given one grain of calomel every hour. Improvement followed immediately, and had been steadily progressive. He could not recall a single case of secondary syphilis of the brain in which there had not been a persistently subnormal temperature. This might prove a diagnostic aid in obscure cases.

Dr. **E. D. Ferguson**, Troy, said that about a dozen years ago Dr. Savage, of London, had told him, in the course of conversation, that he had never seen a gumma of the brain. Whether or not his experience has been exceptional he could not say, but he felt satisfied that it was not uncommon to diagnose gumma of the brain when some other lesion was present. Again, it should be remembered that potassium iodid undoubtedly has a favorable influence on other pathologic lesions of the body than those associated with constitutional syphilis. In the early stages of atheroma, for example, benefit was often noted from the administration of potassium iodid.

Dr. **W. A. White**, of the Binghamton State Hospital, did not think there was anything in the immediate symptomatology which would indicate actual destructive lesion of the nerve elements. The prognosis should always be tentative on that account. For instance, a person with obliterating endarteritis might have a slight hemiplegia, and yet instead of complete recovery, more or less permanent weakness might result. Secondary softening was another sequel which should be borne in mind when considering the prognosis. Probably 80 per cent. of paretics give a probable or an absolute history of syphilis. Those who develop general paralysis are apt to be persons having mental proclivities which lead them to such excesses in life as especially expose them to syphilis. All cases of paresis present elevation of temperature at some stage. This is particularly true of the convulsive crisis and the apoplectiform or hemiplegic attacks. If paresis were a syphilitic disease, this subnormal temperature would be of special interest in connection with the remarks already made. So eminent an authority as Dr. M. Allen Starr stated that gumma of the brain was a very common condition; probably 25 per cent. of all cerebral tumors were gummata. Whether or not they were gummata in the sense referred to by Dr. Ferguson probably depended largely on the definition of a gumma.

REORGANIZATION OF THE NEW YORK STATE MEDICAL ASSOCIATION.

Dr. **Frederick Holme Wiggin**, New York, Chairman of the Committee on Reorganization, said it must be evident to those who were in touch with the medical profession, that there was a sad lack of proper organization. His attention had been called to this matter most pointedly in connection with efforts to remedy the dispensary abuse. Several years ago, at a dinner of the Society of Alumni of Bellevue Hospital, one of the chief officials of New York City had made a statement that, in his opinion, physicians had no influence. If this opinion were correct, it was most significant, and required very thoughtful consideration. The public generally exacts a great deal from physicians, and yet it has a very low estimate of the medical profession.

In looking for the remedy for this state of affairs, it seemed necessary that the profession should organize into a compact body, which would serve the public faithfully, and, at the same time protect physicians against unjust persecution. In the first place, it was necessary to have organization. This organization should begin in the county, and from this pass to the state, and to the national association. The present mode of becoming a member of the New York State Medical Association seemed to be defective, and under the control of a few. The underlying principle of reorganization was home rule. It was proposed that wherever there were ten members of the New York State Medical Association in any county, they should form a subordinate county association. Membership in this county association should carry with it membership in the state association, and eligibility to membership in the national organization—the American Medical Association. In counties not having such a county association, those desiring to become members of the state association should apply to the District Branch Association. Already the New York, Kings, Erie, Genessee and Wyoming county societies had become subordinate county associations of the State Association, so that instead of having a membership of 600, there is now a membership of about 1400 in the state association, with every indication that this number will soon be increased to 2000. *The branch associations elect their own officers, and the* presidents of these branch associations are members of the council of the state association.

Another feature of this scheme of reorganization is the publication of a medical directory for its members, as only by such means can the publication be properly controlled and improper advertisements kept out. Already the work done in this direction on the medical directory has borne good fruit, for it had been the entering wedge by which The Journal had been persuaded to clean up its advertising columns and exclude $6000 worth of objectionable advertising. To show their appreciation of this concession, the New York physicians had added more than two hundred members to the American Medical Association.

Another important feature is a means of protecting members against unjust malpractice suits. It is almost certain that such organized protection will be a most potent and salutary means of preventing the very common speculative suits for malpractice. In the future, if it should seem wise, a small death benefit might be paid to the members.

Dr. E. D. Ferguson said the very fact that the New York State Medical Association was now a chartered body was a most significant one. The association was now a creature of the legislature of the state of New York so far as its legal rights and responsibilities are concerned. Those making application, and accepted as members prior to July 1 are charter members of the state association. The same was true of all who are now members of the association, and who pay before that date.

The American Medical Association is the pivotal point of organization of the medical profession in this country, and to become a member of that organization should be the prime object of all physicians in this country. It is now fast becoming so, although at one time there had been a disposition to sneer at the Association. The theological rule of once a member, always a member, did not apply to the American Medical Association. One might become a permanent member so far as its scientific proceedings were concerned, by continuing in the membership of one of the subordinate affiliated bodies. The time had come to insist upon this. A fee of $5 not only pays for membership in the national organization, but secures for one year probably the best weekly medical journal published anywhere.

ALCOHOL IN THERAPEUTICS.

Dr. H. D. Didama, Syracuse, quoted Holt as saying that alcoholic stimulants are no doubt greatly abused in the hands of many practitioners. but that they are well tolerated by many children, even young infants, and that for a child of four years one ounce of whisky was not too much to begin with. Osler says that some of the effects of alcohol are irritability of temper, impaired judgment, enfeebled will, catarrh of the stomach, disease of the liver and kidneys, yet he adds that "alcohol may be given when the pulse flags in delirium tremens, and, that in moderation, wine, beer, and spirits may be taken throughout a long life without impairing the general health or causing disease of any organ." The unanimous testimony of athletes is that alcohol is harmful, and it is already ancient history that Arctic explorers withhold all alcohol from their companies. and that General Kitchener cut off the usual ration of grog from his men though they were marching over the hot sands of Africa and fighting bravely with the enemy. Brunton expresses the opinion that alcohol and strychnin are antagonistic, and yet they are often given together. Victor Horsley, in a lecture delivered April 27, 1900, reported certain experiments which demonstrated that the effect of alcohol on the brain is first an apparent quickening of the cerebral act, lasting for a few minutes, and that for a period of three or four hours this cerebral activity is diminished. The number of observers who are of the opinion that alcohol is an anesthetic rather than a depressant is rapidly increasing.

Dr. F. H. Wiggin said that, without having any bias on the subject, he had found that year after year he used less alcohol. He had found that hot peptonized milk would stimulate patients after abdominal operations much better than alcohol in any form.

Dr. E. D. Ferguson said that all had been interested in the experiments of Professor Atwater regarding the possible utilization of alcohol as a food. Probably most of us would not rely upon it as a food so much as for something else.

Dr. J. H. Martin, Binghamton, said that early in his practice he had made use of alcohol in certain classes of cases in which he had been taught that it was useful, but not having obtained the desired effects, had discarded it. In the last ten had been as successful as before. There were a host of other years he had not used it at all as a cardiac stimulant, and he and better cardiac stimulants.

Dr. Henry C. Hendrick, McGrawville, said that he had found glycerin a much better preservative of remedies than alcohol.

Dr. J. M. Farrington here called attention to the fact that at the present time there were on the market extracts made with acetic acid instead of alcohol.

Dr. Frank D. Reese, Cortland, thanked Dr. Didama for his paper; and added that of recent years he had had better success without than with alcohol.

Dr. R. S. Harnden, Waverly, said that about twenty years ago he had been asked to sign a pledge not to use alcohol in his practice, but he had at that time declined, as he felt that he could not practice medicine successfully without alcohol. At one time he had been a heroic user of alcohol as a remedy for diphtheria, but to-day he secured better results without alcohol in any form. He used antitoxin, of course.

Dr. E. D. Ferguson thought many other drugs besides alcohol had done harm, and great harm. There could be no doubt that alcohol was often prescribed when it was not indicated; nevertheless it was a remedy which had a definite and useful action, though this was hard to define. He was in hearty sympathy with anything which would limit the abuse of alcohol, but he did not think its improper use would be abolished by asserting it had no place as a drug.

Dr. W. A. White, Binghamton, said he was fully convinced that alcohol had a value, though he was not so enthusiastic about it as at one time. He could recall cases where he was convinced he had saved life by its use. One of these cases was that of an old alcoholic who was on the verge of delirium tremens after an injury, and in whom the attack was aborted and his life apparently saved by the use of alcohol. In justice to Professor Atwater he would say that he defines food as any substance which nourishes the body by supplying the waste which takes place in its tissues, or any substance which supplies energy. In this second class he places alcohol. It certainly was capable of doing this, because it was oxidized in the system, and was not excreted as alcohol. Alcohol, like most all drugs capable of good, was capable of evil in equal proportion. There was perhaps no other drug in regard to which so much idiosyncrasy was shown. In the last number of the *American Journal of Psychology* were detailed some interesting experiments bearing on the effect of alcohol on the mental state. These experiments show that for about half an hour after its moderate administration, the mental working force of the individual is increased. It was not claimed that this effect was more than temporary. He believed the only way to determine the actual status of alcohol as a remedy was by careful experimentation in the laboratory rather than by making sweeping statements as to its detrimental influence.

Dr. J. M. Farrington said that he had given alcohol very freely in the early years of his practice, because he had been taught to do so, but personal observations had made him lose confidence in its value.

EXOPHTHALMIC GOITER.

Dr. F. W. Higgins, Cortland, read this paper, which will be published in a future edition of The Journal.

ABUSE OF THE OBSTETRIC FORCEPS.

Dr. W. L. Ayer, Owego, said that the obstetric forceps might be life-destroying as well as life-saving. His observation had been that the less the experience of the practitioner, the more frequently did he make use of instruments in obstetrics. The strongest argument for their too frequent use comes from the gynecologists. He protested against using the obstetric forceps regardless of the factors of delay, or as a mere convenience to the medical attendant. It should be made a rule, whenever possible, not to employ the forceps without calling counsel. Statistics show that the forceps are used more frequently in this country and England than on the Continent. This is dependent quite probably on racial peculiarities and on different conditions under which patients are brought to the hospital in the different countries. According to recent statistics it appeared that they were used about once in fifteen cases, and this he considered too large a proportion—a revulsion from the days when they were used too seldom.

Dr. F. W. Higgins said that it was not the use, but the abuse of the forceps which should be condemned. He had been recently called to see a case in which forceps had been applied to a face presentation, and the slipping of the forceps had produced an extensive laceration of the vagina. If the true presentation was recognized, and the operation done under proper precautions, he was a thorough believer in the use of the forceps.

Dr. R. S. Harnden remarked that to-day he did not use forceps once where thirty years ago he used them a dozen times. Experience had taught him that nature was the best accoucheur, and the nearer we follow her work the better for the patient. Occasionally their application would save the child, it is true, but he would agree with the author of the paper, that the extensive use of the forceps was not to be recommended.

Dr. Styles, Owego, said that the older one grows the less frequently does he employ obstetric instruments, and then to save time and suffering alone. The physician should be held accountable for the use of the forceps. Too many young men like the *éclat* of operative cases, but as their hair becomes white, they use instruments much less. In the large majority of cases of injury from the use of forceps, it is the result of ignorance or carelessness.

Dr. Farnham, Binghamton, referred to the collective investigation made by a colleague from all classes of medical practitioners with regard to the use of forceps. One of the replies received was from a man who said, "Give me plenty of lard and plenty of time, and I will not have much use for obstetric forceps." A reasonable time should always be allowed to elapse before resorting to their use, and such conservatism, he thought, would be better for both mother and child.

Dr. E. D. Ferguson said that he could not see how aseptic forceps introduced into the aseptic parturient canal through an aseptic vulva with reasonable care could do the woman any harm. These instruments were often used when they were not indicated, and they were often blamed for results dependent entirely upon other conditions. A woman suffering agony from labor prolonged by tardy extension should be very thankful to the physician who cuts short her suffering by the aseptic and skilful application of the forceps.

Dr. Chittenden said that he believed, with Dr. Ferguson, in cleanliness and in removing the forceps before the delivery of the head. He had practiced many years before he had owned a pair of forceps, yet the labors had terminated satisfactorily.

ELECTION OF OFFICERS.

Dr. T. A. Wales, of Elmira, was elected president, and Dr. Chauncy P. Biggs, of Ithaca, secretary, for the ensuing year.

Chicago Surgical Society.

June 1, 1900.

SURGICAL EXCLUSION OF INTESTINE.

Dr. Carl Beck said: "I will not take up much time, but bring the question before the society in order to elicit some discussion on a subject which is of great importance in intestinal surgery. Historically it has developed about like this: In 1892 Salzer recommended exclusion of a portion of the bowel for incurable tumors or incurable inflammatory conditions. He did not perform the operation himself, but shortly afterward one of Billroth's assistants performed an operation of that kind. Long before, however, the same question had been brought up by the physiologists, who had selected a portion of the bowel, excluded and closed it from both sides, to examine the physiologic effect of the discharge. Also two Viennese physiologists made this experiment first and examined the physiologic functions of different portions of the intestine. From that time until the present there are, according to the latest paper published, twenty-four cases of surgical *total exclusion* of the bowels. What is total exclusion of the bowel? We distinguish partial and total exclusion. Partial exclusion is, for instance, exclusion by gastroenterostomy or gastroanastomosis. A portion of a loop of the bowel is excluded, but communicates with the general intestine. If we close up the two ends entirely and leave the excluded portion in the abdominal cavity or make it communicate with the outside by a fistula, we have a total exclusion. This experiment has been tried on animals and men. In animals it has been found that when the intestine was normal a piece of the bowel could be excluded without any bad consequences. You have read about the experiments of Hermann, who left portions of the side-tracked bowel inside the abdominal cavity, which remained there and became a cyst, the fluid doing no harm. In man it is different; this experiment is entirely impossible in man, as there are always microbes in the excluded portion, and it is invariably necessary to make a communication of the excluded portions with the outside.

"The indications for this operation are, first incurable fistula; intestinal fistula which can not be cured by any other method can be cured by total exclusion of the bowel, by closing up the bowel on both sides of the fistula and bringing the ends of the severed portions, distal and proximal, together. I have operated so far in four cases, in one with a fistula exclusion, only a few days ago. The reasons for these operations were different. The case I illustrate is one I have already demonstrated before the Chicago Medical Society, an incurable fistula. Eight laparotomies were necessary to cure the fistula. First, operation was for appendicitis. There was a large abscess cavity. I tried by different methods to close a fecal opening, which I finally found away behind the colon ascendens. The seventh operation, side-tracking of the bowel, was done in this way: The cecum was severed and the ileum was severed; this portion of the bowel communicating by the fistula with the outside was left *in situ* and the two ends united by a Murphy button. The Murphy button sloughed through and I had a fecal fistula again. This could only happen by the Murphy button sloughing into the old portion that was agglutinated to the newly united bowel. I had to make another exclusion, which makes it a unique case. The second time I used Frank's coupler, and this time it succeeded. The Murphy button has been in the bowel ever since and has apparently caused no damage; as far as pressure and other symptoms are concerned he is perfectly well. There are many pockets of excluded bowel, secreting now and then a cheesy white mass which comes out and may be squeezed out by the patient every two or three weeks. In the meantime he does not discharge anything outside; he squeezes out this thickened, cheesy mass, which relieves him, and afterward he feels well. I have lately operated on another case of tuberculosis, with acute symptoms of obstruction. In this case also it was impossible to do total resection of the tubercular mass. I left that in situ and made exclusion of this portion. I have not opened the excluded portion yet toward the outside, but I will do it in a few days because I am afraid it will accumulate masses which will perforate inward instead of outward. The two other cases were similar but not as extensive.

"The experience I have gained from these four cases differs somewhat from the experience of others. There is, for instance, Obalinski, who claims that the excluded portions atrophied and formed an entirely solid mass. He has made a section of a case after eight months' exclusion of the bowel and he has found the portion he excluded totally solid. Such a thing eight months afterward, I think, is impossible. He probably found some portion which has not been the bowel. This is the only case which is claimed to have gone from total exclusion to cicatrization. Perhaps it was a kind of bowel which had no mucous membrane. The other cases have all been treated the same way, some of them scraped and cauterized. All of these methods seem objectionable. I think the best way is to leave it as it is and keep drainage as long as possible, and allow the patient to remove the contents of such excluded bowel."

Dr. L. L. McArthur said he would like to refer to a case in which he was driven into this operation by an accident in the use of the Murphy button. The patient was an old man with carcinoma at the ileo-cecal valve, of slow development, causing hypertrophy of the ileum to the size of the colon, and atrophy of the colon beyond the stricture, to the size of a small intestine, producing symptoms to such an extent that the patient was extremely emaciated and exhausted. The only thing in contemplation at the time of operation was to make an anastomosis between the ileum and the ascending colon. The fact that the ileum was so markedly hypertrophied made it easy to insert the half of the button for that part of the intestine, and the fact that the colon had atrophied to such an extent as to be smaller than the small intestine made it difficult to recognize the colon and difficult to insert the strong suture which is usually put in before incising the bowel for the second half of the button, due to some faulty dipping of the needle with failure to grasp the mucous membrane, that half of the button tore it loose from its attachment. The button was inserted in the colon, purse-string tightened, and when the ileum and colon were buttoned together fecal mater entered between the muscular and peritoneal walls of the colon. He immediately clamped the ileum again and found it necessary to excise that portion of the colon which has been infiltrated, to turn in its end where it had not been infiltrated, and to make an end-to-side anastomosis of the colon to the side of the ileum, not making a total, but a partial exclusion. He stopped at that, because the patient was in such a delicate condition. Emphasis should be made of the fact that where the distal portion of the intestine is atrophic an incision should be made in that portion and the overlapping stitch used to catch the mucous membrane firmly, and not let it be pushed away, as that may make a faulty union and fatal outcome.

In the case of the young boy that Dr. Owens operated on at the World's Fair for tuberculosis of the ileum from tubercular appendicitis, exclusion of the ileum was made, and the process being tubercular, later a successful effort was made to excise the cecum. It was tubercular and was left excluded for the time. A year later the boy died of pulmonary tuberculosis.

Dr. D. A. K. Steele said: "The case cited by Dr. McArthur illustrates what I intended saying with regard to the facility with which we may criticise cases as reported. Theoretically we ought always to have an ideal result; we ought to be able to do the very best thing at a given time and operation, but the fact is, frequently these operations are done to save life; usually they are done for the purpose of prolonging or making life more comfortable. I felt somewhat like asking Dr. Beck why the Murphy button was left in the portion of the bowel put out of commission, just as Dr. Bevan asked, why it was not removed in its entirety. The reason is apparent, I think, to those of us who have seen these cases. We know the impossibility of doing an ideal operation under such circumstances. There is a mass of tissue matted together which is difficult to recognize; the condition of the patient precludes a prolonged and more difficult operation than anastomosis, cutting off and excluding a portion for the direction of the fecal current through a new channel. Most of the cases I have seen have been of the class where operation was done for the purpose of saving life; where the condition of the patient would not permit the prolonging of the operation. I think Dr. McArthur will remember a case he operated on in the Chicago Hospital, where, in malignant disease of the cecum a simple lateral anastomosis was all that it was possible to do on account of the infiltration of the tissues and evident hopelessness of the case, but the life of the woman was prolonged some months with comparative comfort. Another, more recent case, comes to mind in which acute obstruction required the exclusion of the bowel in a lady, for a very long fibrous stricture of the rectum and apparently a portion of the cecum. An artificial opening or the left inguinal colostomy was the only proper operation to save the life of the patient. Subsequently the complete removal of the mass that takes the place of the rectum can be done. I allude to these cases simply to illustrate the impossibility of always doing an ideal operation."

Dr. Carl Beck, in closing the discussion, said: "I will first answer the question of Dr. Bevan, why I did not remove this bowel. I tried in the first six operations to close the bowel by suture. You can imagine that the intestines were so matted together that I really could not recognize any portion of the cecum or ileum in that region, and it was very difficult to leave the whole matted portion outside. It was hardly possible to find the distal and the proximal portion because of the recent adhesions. This operation was done shortly after the Murphy button operation, and adhesions of the whole intestinal tract had to be severed, and it was difficult to determine which portion was running upward and which downward, so that we should not attach two faulty portions together. I did not remove the Murphy button, because at the time I did the operation I thought it had passed through the fistula. I did not watch it and the nurses told me that it had been thrown out, but I found afterward that the button was there. I think it is in one of the pockets, and it is not doing any harm, and the boy does not want it removed."

AMERICAN.

1. **San Francisco's Plague Cases.**—In this article Pillsbury argues that the San Francisco plague cases, as demonstrated bacteriologically, were not true plague, but more likely due to the chicken-cholera bacillus, which closely resembles plague bacteria, but has certain peculiarities that distinguish it, and which he claims he has found in one case examined by him that had also been declared a typical instance of a pneumonic form of bubonic plague. He does not appear to have facts as regards the other cases examined by the City Health Board and the Marine-Hospital officers, but he assumes that they were all the same. He also argues that eleven of the thirteen cases of bubonic plague could hardly occur in the sporadic form without any connection with each other and without any evident transmission of the disease to others by them. He also claims that as no infected ships had arrived, as the clinical histories in all of these cases were distinct from those of any other recorded cases of plague, and as they were diagnosed by bacteriologic and inoculation experiments only, the facts are not conclusive as to the existence of the disease.

2. **Adenocarcinoma of the Gallbladder.**—Warthin discusses the conditions found in his case, which he thinks of great interest. Reviewed briefly, they are given as follows: Cholelithiasis followed by primary carcinoma of gallbladder, obstructive jaundice, compensatory hypertrophy of the pancreas, carcinomatous infiltration of the adrenals, melanosis of the skin—Addison's disease—followed by vitiligo.

3. **Tuberculosis of the Skin.**—Ravenel reports three cases of inoculation from bovine tuberculosis causing what he thinks was true tuberculosis of the skin, and dwells on the importance of recognizing contagion from this source. In two of his cases no bacterial findings were reported. With inoculation experiments, one caused tuberculosis in the guinea-pig. In the third case tubercle bacilli were found in sections from the diseased nodule excised. He believes that the greater virulence of bovine tuberculosis holds good for man as well as for other animals, and the cases that he has reported, with some from other sources, prove that the pathogenic power is fully as great as that of germs from the human source.

4.—See also The Journal of July 21, p. 134.

5. **Consanguineous Marriages.**——Irwell discusses the chances of degeneration following consanguineous marriages, quotes authorities at length and gives instances. The general result of his inquiry is not positively stated, from the fact that the illustrations given by him, as he himself admits, have more than one interpretation. In all, however, we have a specially healthy people to deal with in these cases, hence the comparative apparent innocuousness of consanguineous marriages. If such unions were common among neurotics and degenerates, he believes the results would be disastrous.

7. **Acromegaly and Giantism.**—Hutchinson finds from his study thus far on the subject of the phenomena of giantism, that the great number of over-growths are found at or near the tips of the segment-crescents, as in acromegaly, differing from the latter mainly that it is not exclusively confined to the tip of the segment or last division of the limb; that the facial part of the skull is enlarged out of all proportion, particularly in the region of the lower jaw, and that the condition, whether normal or morbid, distinctly tends to shortness of life and physical vigor. The giant is distinctly below par, and death usually comes from a steady increase of this weakness, or some trifling accident or mild intercurrent disease. The sexual power in a great majority of cases is far below par. There is a decided predominance of males among the victims of this condition. In all of these there is a decided parallel with acromegaly. Lastly, and of greatest interest, is the fact that the one morbid condition peculiar to both these disturbances of nutrition, the enlargement of the pituitary body, is found in the large majority of the cases of both. He reports and illustrates a number of cases of giantism. In his next communication he will give the results of his study on the microscopic nature of the over-growth of the glands.

8. **Prevention of Colds.**—Lockard's article is mainly a plea for the hardening and training processes for infants, and a protest against the effeminate methods of living, superheating of rooms, over-clothing, etc., so largely in vogue. As an example of the effects of training of infants, he reports the case of a child of Professor Stagg, of the University of Chicago. At two months, with a little aid, he could turn somersaults and stand on his head; at three months he could walk, and at seven months could raise himself from the recumbent to the sitting posture without using his arms.

9. **Syphilis of the Brain.**—In this instalment of his article Eskridge reviews the principal points of general and local diagnosis of syphilitic cerebral lesions; headache, disturbance of sleep, collateral symptoms like iritis, presence of secondary or tertiary manifestations, epilepsy, hemiplegia, etc. The forms of lesions, syphilitic growths, and chronic local syphilitic meningitis, with their symptoms of isolated nerve lesions are described. The prognosis is better the earlier the specific treatment is instituted, but the scars that are left are not amenable to therapeutics. The more he sees of syphilis of the brain the more difficult seems to him the problem of its treatment. Prevention of the tertiary lesions is largely to be secured by potassium iodid, usually by a sort of intermittent treatment covering a considerable period of time. The specific treatment must be governed by the acuity of the case and the results of medication. What we learn from a study of this subject is that, for a certain time, antisyphilitic agents may be given to the point of toleration for the removal of gummata, and that there are numerous non-specific intracranial lesions resulting from specific causes, for which specific medication is ineffective.

10. **Hysteria.**—According to Walter, if a massive culture of the colon bacillus originally taken from non-infectious sources is administered to subjects of hysteria of active or convulsive type—latent or post-hysterical phenomena, such as paralysis being excluded—the patient is restored to health so far as the hysteria is concerned, though debility or neurasthenic phenomena may remain indefinitely. He claims that the uniformity of this result makes the treatment a sort of specific. He takes the bacillus from the stomach or intestinal mucosa of the hog, from the dejections of the same animal or from the barnyard fowls, and makes agar cultures. When it is all developed it can be scraped off, suspended in water and mixed with some indifferent substance, as starch, and administered in capsules. The well-matured growth on one Petri dish may serve to make from three to six doses. This given three times a day will be sufficient. The growth should be fresh, otherwise no results are obtained. This treatment does not seem to be very attractive.

11. **Milk.**—The motive of Rotch's article is the importance of getting safer milk for children's use, and he emphasizes the fact that it will be necessarily somewhat expensive. We can not have the required care given and the quality insured at the ordinary cheap prices. The chief principles insisted on are: 1. That the milk must be obtained from healthy cows by the most cleanly and antiseptic methods known. 2. That it must be taken care of under the most strict precautions. 3. That it must be delivered to the consumer as quickly as possible.

12. **Posterior Colpotomy.**—The pathology of pelvic suppuration in the female is described by Cumston, together with its etiology, symptoms, etc. The advantages of posterior colpotomy for the relief of many cases of this condition are insisted on. He thinks that it is a justifiable procedure in a large majority of cases and, if we can cure the patient by a simple operation, that is the one to be selected. The operation is described and its safety and simplicity shown. While it is not claimed that it will cure all cases, it has a field of usefulness not as fully appreciated as might be.

15. **Appendicitis and Typhoid Fever.**—The object of this article is first to call attention to the cases of typhoid which begin with symptoms of appendicitis and, second, to the cases of typhoid with later-developing appendicular symptoms. Both classes of these are illustrated by cases. Hare believes that appendicular symptoms in the first stage of typhoid are by

no means rare, and a differential diagnosis is important. The leucocytosis, which will be of use in some cases, is not always a perfect guide, though its absence may be of some value. In the ordinary cases of appendicitis it is a well-known fact that the white blood-corpuscles are increased in number, while the reverse is the case in typhoid. The possibility of a patient being about to pass through a course of typhoid is not a contraindication to operation, though it seriously complicates the case.

16. **Ductless Gland Preparations.**—Cunningham, noticing first the enormous number of preparations on the market, reviews the different ones that have been more prominently advertised. The pituitary extract has not been a success, according to clinical experience. Suprarenal extract has a decided utility in local complications of mucous membranes, and, when used internally, it seems to have a beneficial result in certain cases of asthma, cardiac trouble with diseased arteries and Graves' disease. We may also say that it has abbreviated about 58 per cent. of the cases of Addison's disease, but its therapeutic value in general diseases is not yet decided. He does not speak with any enthusiasm as regards thymus extract, though he has had benefit from it in some instances. He thinks the excellent results sometimes obtained with it may be attributed to the nutritious food the patients receive when they eat several ounces of slightly cooked thymus daily. The therapeutic position of thyroid extract is well assured in certain forms of disease like myxedema and where the disorder is due to diminished thyroid function. The author does not use the ordinary commercial desiccated thyroid extract, but prefers the more reliable and equally active purified colloid obtained by himself from fresh sheep thyroid by precipitating an alkaline solution with glacial acetic acid.

17. **Iron Iodid.**—Wilson has found iron iodid effective in several cases of arthritis where the ordinary rheumatic remedies failed. He publishes cases illustrating his statement. He finds this method especially valuable in gonorrheal arthritis, and uses it in half-dram doses of the syrup, gradually increased with very satisfactory results. Several of his associates in clinical work have also tested the treatment with equal advantage.

22. **Castration for Prostatic Atrophy.**—The history of the operation of castration for prostatic atrophy is reviewed by Keyes, who sums up his conclusions on the subject as follows:

1. Experiments, whether on man or the lower animals, relating to the normal prostate do not of necessity apply to the enlarged prostate.

2. I know of no direct pathological evidence that castration has ever caused atrophy of a hypertrophied prostrate.

3. There is direct pathological evidence that in a few cases castration has failed to cause atrophy of the hypertrophied prostate.

4. The majority of cases reported thus far have been labeled "cured" or "improved" so soon after operation that *many of them are doubtless instances of local depletion.*

5. Clinical evidence of this is afforded by relapses occurring months after the operation.

6. Of the permanent cures some may well be instances of permanent advantages derived from reduced congestion.

7. The clinical evidence as to the actual atrophy of the prostate after castration lacks, as yet, its scientific confirmation, and has failed thus far to prove its title to the surgeon's credence.

23. **Neglected Clinical Opportunities.**—Knopf points out the defects of clinical instruction in our great medical centers and the comparatively limited opportunities for hospital interneship according to our present system. He suggests the unification of our medical colleges and the appointment to hospital positions only of those who can act as clinical instructors without regard to college affiliation, to the partial suppression of didactic lectures and their substitution by clinical work. He gives his plans in detail.

24. **Strabismus.**—This paper by Ranney is along the usual line of magnifying effects on the general conditions of ocular abnormalities. He thinks that a small percentage of cases of cross-eye owe their deformities to refractive errors. Serious nervous phenomena may co-exist in this class of cases. Where this is not the case, the phenomena do not occur. Those who suffer only occasionally are especially liable to reflex nervous conditions. He points out the methods of testing, the advantages of the phorometer and the tropometer, and the value of operations, which are now-a-days done without pain under cocain.

26. **Dermatitis Herpetiformis.**—Ravogli's article is a rather lengthy description of this condition, the prognosis of which is not very bad, but, in fact, is rather favorable. The treatment recommended is attention to the general condition of the subject, good diet, avoidance of mental strain, worry, overwork, and alcohol, care as to the digestive organs, condition of the bowels, and the use of tonics. Arsenic has not proved beneficial in his hands. The external treatment with carbolic acid solutions, ichthyol, etc., is of importance. Permanent recovery is to be expected in these cases.

28. **Antistreptococcic Serum in Anemia.**—DeWitt reports two cases, one of pernicious, the other of simple, anemia, in which he gave injections of antistreptococcic serum with the very best results, though he administered at the same time iron and arsenic. He does not, however, attribute the good results to these latter agents. The dose of the serum was 8 c.c. at intervals of two or three days.

29. **Hypnotism in Therapeutics.**—Kuh relates cases where *hypnotism had a disastrous effect and states as of his own* knowledge that Krafft-Ebing has had unpleasant results from this agency, though he has carefully refrained from publishing them. He does not believe, moreover, that it is more beneficial than other equally available and safer remedies. He concludes that hypnotism is not so safe a remedy as others employed for the same purpose, and that it is not more active in relieving most of these symptoms of disease for the cure of which it is used than other methods. Since the very patients from whom we may expect good results—the neurotics—are also the ones most liable to injury, we should be doubly careful in employing it.

30. **The Nerves in Consumption.**—Mays discusses the nervous influence in consumption and thinks that the most beneficial results will follow the treatment directed to the protection of the nervous system.

38. **Abdominal Injuries Without Skin Lesions.**—These cases, which are often very important and also difficult of diagnosis, are treated at length by Vaughan, who discusses the symptoms and methods of operation, and reports cases which have occurred in his practice. The questions for the surgeon's consideration are: Does the lesion require celiotomy? What organ is probably injured? The temperature is not reliable, as it is usually lower in serious cases—probably from shock—and rises later. The pulse is increased and is often a good index in regard to the cases, a weak thready pulse indicating trouble. Pain and tenderness are always present to a greater or less degree, and may help in localizing the injury. Vomiting is almost certain to occur when the stomach is involved and may appear with injuries to the intestines and liver. Restlessness and thirst indicate hemorrhage or peritonitis. A pinched expression with dilatation of nasal alæ is a valuable symptom, but its absence is not conclusive. Rigidity of the abdominal muscles with or without distension is another valuable symptom, but not always an early one. Blood in the vomit, stools or urine is also to be considered. After opening the abdomen he first stops the hemorrhage, and yards of gauze may be demanded in some cases when the sources of hemorrhage are numerous. Compression of the abdominal aorta may be necessary in extreme cases. Laceration of the stomach or intestines and rents in the solid viscera should be sutured, but extensive laceration of the spleen or one kidney requires removal of the organ. If the contents of the stomach or bowel have escaped into the peritoneal cavity, free irrigation with salt solution is necessary, but if only blood is found, sponging it out will be sufficient. Drainage is a question to be decided in each case. The [illegible] ion of salt parts to 1000, has [illegible] patient cases of rupture [illegible] of sig laceration of [illegible] kid

ture of the diaphragm. In none of the cases reported was there recovery.

42.—See also ¶ 71.

43. **Permanent Catheterization.**—Eastman remarks on the tolerance of the urethra for the rubber catheter and thinks the danger of permanent catheterization has been somewhat overestimated. After it has been in position two or three days, a distinct tolerance is established. He reports two or three cases illustrating these points.

51.—See abstract in THE JOURNAL, xxxiv, p. 1338.

52.—Ibid., p. 1339.

53. **Examination of the Colon.**—Abbott describes his method of examining the rectum and lower portion of the sigmoid flexure. He found by experimental demonstrations that it is possible to inspect ten to twelve inches of the lower bowel without serious difficulty. The instruments which he has used for this purpose are only straight flat pieces of steel with four inches bent down for a handle. The sizes he has found most convenient are one twelve inches long and three-fourths of an inch wide; one ten inches long and one-half an inch wide; one eight inches long and one-quarter of an inch wide. Of course, great care must be used when the caliber of the bowel is reduced or the resiliency diminished by inflammation or tumors.

54. **Ectopic Pregnancy.**—Manierre reports cases of ectopic pregnancy operated on before rupture. The pathologic report is given by Dr. M. Herzog. In these cases pregnancy was only a few weeks old and was accompanied by uterine hemorrhage, which suggests the possibility of this as a useful sign that the fetus had died from intervillous hemorrhage. If it be possible, as Herzog remarks, to establish a set of symptoms characteristic of intervillous hemorrhage, it will be a valuable practical point and may save many patients from the dangers following rupture.

64. **Contagious and Infectious Diseases in Indiana.**—The diseases considered by the Secretary of the Indiana State Board of Health are tuberculosis, typhoid, diphtheria, scarlet fever and the diarrheal diseases of infancy. He thinks that the schools are largely the disseminators of diphtheria and scarlet fever, and that they should be cleansed and disinfected thoroughly.

65.—See abstract in THE JOURNAL, xxxiv, p. 1415.

70. **Retinitis Albuminurica.**—The conclusions of Alter's paper are, in substance, as follows: 1. Retinitis albuminurica indicates a highly toxic condition of the blood, which, in chronic kidney diseases, will prove fatal within one, or, at most, two years. 2. The eye symptoms in such cases are always the first definite demonstrable lesion of chronic kidney disease; particularly is this true of the shrunken kidney. 3. Retinitis from Bright's disease assumes two forms—exudative and degenerative. In the first, occurring with acute nephritis, recovery with serviceable vision is possible. In the second, connected with chronic nephritis, recovery is impossible. 4. Retinitis occurring in pregnancy gives evidence of a toxic condition of the blood, which endangers the life of both mother and child, and unless remedies have an inhibitive effect, abortion is justifiable, especially when retinitis occurs in the early stages of pregnancy, or if previous pregnancy has already left its imprint on the retina of the optic nerve. 5. The appearance of the lesion in albuminuria so vividly described first by Liebreich does not agree with the ophthalmoscopic picture in the majority of cases. Probably not more than one-half agree with his description. The paper concludes with a plea for the more general use of the ophthalmoscope by the practitioner.

71. **Organic Obstructions to Defecation.**—Martin's article pleads for the surgical treatment of mechanical disturbances of defecation due to the valves which he has described. See also title 42.

76. **Digestive Disturbances in Tuberculosis.**—The questions asked by Van Sant are: 1. Are dyspeptics more prone to tuberculosis than others? 2. Are tuberculous sufferers more prone to the development of digestive disorders than others? The answer to the first is, he thinks, absolutely in the affirmative, hence the importance of attending to digestive disturbances in persons predisposed or exposed to the disease. The answer to the second is also in the affirmative. He thinks the digestive disorders of consumptives, as a rule, purely functional, but they may represent organic changes. The important bearing of these disorders can not be too greatly emphasized. We can not too promptly attack and attempt to cure these harmful conditions and meet any disease that may exist.

78. **Chloretone.**—Lee finds chloretone one of the most satisfactory narcotics, and better results have been obtained by it than by any other remedy of its class that he has prescribed. It has the effect of keeping up a soothing and satisfied condition after awakening. He had also had the very best results in a case of senile chorea of great severity. Nothing could have had a happier effect than a six-grain dose of this hypnotic given every four hours. He also reports excellent results in several cases of whooping-cough.

86. **Cancer of the Cervix.**—Clark reviews the history of operative treatment of cancer of the cervix, reproducing Freund's original case. He has, with others, suggested that the pelvic lymph-glands should be removed in cancer of the uterus, but subsequent investigation has proved that the lymph-glands are not so frequently involved as has been estimated. He thinks that removal of the pelvic lymph-glands is of greater prognostic than therapeutic value. They are freqently not the site of metastases even in cases of excessive involvement of the uterus, as Cullen has shown. As regards the operation, he thinks the modification of the combined method recently suggested by Werder, of Pittsburg, offers the best chances for the thorough removal of the cancerous processes. He first performs an abdominal section and ligates both the ovarian and uterine blood-supplies. The uterus is separated from its pelvic attachments and pushed down into the vagina, after which the peritoneum is whipped together over the site of the operation. This step being completed, the patient is placed in the lithotomy position and, with strong tractors, the uterus is drawn outside the vaginal outlet, which greatly facilitates the excision of a large portion of the vagina either by actual cautery or by knife. Clark feels certain that the cautery is preferable to the knife, as it removes all cancerous tissue that is possible. Treatment of cancer is lamentable from the point of view of radical cure, and by no means what ideal surgery demands. It is to be hoped that a cure may be found by some other than surgical methods. These remarks are especially applied to cancer of the cervix. In cancer of the fundus, recurrences are infrequent after hysterectomy, and the prognosis for complete cure is good.

89. **Blood Changes Following Celiotomy.**—White reports studies of the blood in cases subjected to major gynecologic operations. The prolonged etherization and pathologic lesions have, to a certain extent, their expression in the blood. Postoperative changes in this condition have been only partially studied, and it is his hope to elaborate previous studies in order to see the relation of these reactions to convalescence, and the presence of these reactions in impossible complications that might arise. Counts and estimates were made twenty-four hours before the operation, within five hours after operation, and then every twenty-four hours, until the patient's leucocyte-count had returned to normal, while the patient had so far recovered as to make further examination unnecessary. The percentages of leucocytes do not go hand-in-hand with the daily number of erythrocytes, which is undoubtedly due to change in the blood in many cases. The erythrocytic count previous to operation showed in each of these cases a greater richness of blood than would be expected from a general inspection of the patient. The preparation of the patient had undoubtedly something to do with this richness, the purgative causing concentration of the blood. The direct effect of the operation on the erythrocytic count within the first five hours was an increase in 34.6 per cent. of the cases and a decrease in 53.8 per cent., while in 11.5 per cent. there was practically no change. In all those which showed an increase there was more or less excessive vomiting, which had a tendency to further concentrate the blood. In the succeeding counts many of the cases showed variations. These were irregular in 26.9 per

cent., with progressive decrease in 38.4 per cent., and progressive increase in 34.6 per cent. Sudden increase or decrease is indicated by such factors as vomiting, fever, loose stools, and a difference in the amount of fluids taken and urine voided. At the final count the erythrocytes were found to have actually decreased in 62 per cent., increased in 23 per cent., and remained stationary in 15 per cent., but the changes were so slight as to hardly deserve consideration. The study of leucocytes offers more distinct features in cases where there is inflammation alone, or inflammation with pus; 53.8 per cent. showed the leucocytes to be within normal numbers, and 46.2 per cent. showed slight leucocytosis. Of these cases 69.2 per per cent. were in the subacute or chronic stage, while 30.8 per cent. were acute. In the seven cases in which neoplasms were present, three were malignant and four benign. Three of the seven cases showed slight increase of leucocytes. Backward displacement of the uterus gave no leucocytosis, while one case of prolapsed ovary gave 12,920, and another case of displacement 10,840. The differential counts in all these cases before operation did not differ from the counts of like pathologic process under the same conditions in other parts of the body. The eosinophila mentioned by Neusser as occurring in diseases of the reproductive apparatus was not found. The increase of leucocytes after operation must be due to various factors, and first among these is the effects of ether. Following this come traumatism and breaking up of adhesions together to produce the post-operative leucocytosis which was constantly seen in these cases. The highest count was recorded within five hours after the operation, excepting in severe cases, where glass drains were used, and tended to fall to normal in a few days, excepting in rare cases, when it was somewhat delayed. The average was 20,975 in the total of his cases. Post-operative leucocytosis consists in a relative and absolute increase of the polymorphonuclear neutrophiles, and absolute increase, at the expense of the other cells in 59.2 per cent.; an absolute increase with increase of other cells as well in 25.9 per cent., and an absolute increase with no change in the number of other cells in 14.9 per cent. of the cases. The polymorphonuclear cells were increased in 40.7 per cent., decreased in 48.1 per cent., and unchanged in 11 per cent. The transitional cells were increased in 56.5 per cent., decreased in 48.1 per cent. and unchanged in 11.0 per cent. The lymphocytes increased in 18.5 per cent., decreased in 70.3 per cent. and remained unaffected in 11.1 per cent. of cases directly following operation. The eosinophiles disappeared in 96.3 per cent. of the cases during the highest leucocytosis; in 3.7 per cent. or one case, they remained, but in reduced numbers. They returned after several days with decrease of leucocytes; their number was then decreased only in three-fourths of the cases, but in one-fourth was apparently increased. Complications during convalescence had their expression in the blood in an absolute increase of the total leucocyte count, or a relative or absolute increase in the polymorphonuclear neutrophiles, or sluggish fall in the total number of cells daily estimated. The author discusses the value of blood-examination in such cases. He thinks that it is only a part of the thorough investigation of the patient and should be considered in this connection. He thinks the range of 5000 to 10,000 leucocytes usually given as normal is too wide a limit, though leucocytosis can hardly be considered to be present when they are under 10,000.

90. **Pernicious Nausea of Pregnancy.**—Davis briefly reports two cases of pernicious vomiting of pregnancy of somewhat unusual types. In the first case the ovum was situated in the cornu of the uterus, and had ruptured into the abdominal cavity. The patient recovered. In the second case there was ectopic gestation with excessive headache and vomiting. The patient finally succumbed. A tumor was found attached to the optic thalamus and another tumor was found in the left kidney which were diagnosed as syncytioma malignum. The pathologic examination is reported in full by Professor Harris, Jefferson Medical College, who remarks that this case strongly suggested a very unusual and peculiar form of parasitism. The syncytial masses were found not only in the kidney and brain tumors, but in the thyroid, liver and other portions of the body, rapidly destroying the tissue with which the new formations came in contact, the whole making a picture familiar to every pathologist in connection with infected processes. He has not found any literature in reference to cases of pernicious nausea in which syncytial growth was an active factor.

94.—Ibid.

95.—Ibid.

96.—Ibid, p. 1415.

97.—Ibid., p. 1414.

98. **Intestinal Anastomosis.**—O'Hara describes a method of intestinal anastomosis consisting of the use of two pairs of forceps clamping the intestine which is excised between them close up to their surfaces and suturing over them. When they are withdrawn, a single stitch or two fills up the opening left. The article is fully illustrated.

100.—See JOURNAL, July 14, p. 86.

101. **Potassium Chlorate.**—Meltzer has experimented on dogs with potassium chlorate and finds that it is a direct poison to the nerve-cells, which are at first intensely excited, then paralyzed by it. He asks whether we may not assume that a certain proportion of it reaches the brain, especially the respiratory center, in sufficient concentration to paralyze it.

102.—This article has appeared elsewhere. See THE JOURNAL, xxxiv, ¶ 123, p. 1481.

108. **Trauma and Joint and Bone Tuberculosis.**—Highsmith reviews the authorities in regard to the possibility of trauma exciting tuberculosis of the bones and joints, and finds as a result of his investigation of the literature and also his own experience that accidents are credited as causative factors where really the evidence is not sufficient to satisfy the intelligent investigator. He asks, too, how many cases of accidents have we seen in subjects of pulmonary tuberculosis when the whole system is reeking with infection, and no manifestation of tuberculosis of the bones at the point of local injury.

117.—See also title 129.

118. **Treatment of Squint.**—The treatment of strabismus from the standpoint of the family physician is summed up by Duncan as follows: 1. In a child aged three years or over, he would in every case (with the exceptions noted) advise a thorough examination of the eyes, so as to ascertain the refraction. 2. He would advise that this be done as soon as possible, but if some weeks must elapse before this can be done, he wouud use atropin drops once, twice or three times a day in both eyes, ordering that the drops be left off for at least two weeks before the child goes to be examined. 3. If it be reported to him that the child needs to wear glasses, he would exercise his influence with the parents to see that they were worn. 4. In case of any hesitancy on the part of the parents to attend to the matter, he would free himself from responsibility by pointing out some of the dangers of delay: 1. The child may be permanently cross-eyed. 2. He may be partially blind. 3. An operation may be needed in after years. 4. The operation, although it may straighten the eye, will not cure the blindness.

119. **Morphia in Puerperal Convulsions.**—Hoig concludes that while morphia is a valuable, and perhaps the most valuable, drug for the control of puerperal convulsions, he is not inclined to call on it in the worst types of the disease with complete suppression of the urine and a comatose state between attacks. In such cases he would prefer to use other remedies for diaphoresis and free action of the bowels. Morphin is much less useful in non-albuminous cases than in those where albumin is present, and may be even harmful in such cases. It is practically of little value before delivery, chloroform being the preferred drug at that period, and to be efficient it is necessary to use it in large doses, as much as .5 grain being borne without harm resulting.

128. **Cancer of the Uterus.**—Coe insists on the importance of early diagnosis as a prerequisite to successful operation

for cancer of the uterus. The proportion of operable cases will be increased only by the general education of the profession and laity regarding the vital significance of hemorrhage as an initial symptom. Every suspicious case should be most rigidly scrutinized, the microscope being also utilized. Before assuming a case as favorable for radical operation a careful examination should be made under anesthesia. Whatever the operation is to be it should be thorough; unless the incision can be made in the healthy tissue, well beyond the diseased area, and all outlying foci can be removed, the operation is palliative rather than curative, hence the probability that abdominal hysterectomy will be the future chosen method.

129.—See also title 117.

136. **Opinion Evidence.**—This article by Palmer reviews the subject of medical expert testimony in a very satisfactory way, showing how its defects that have been so deprecated may very easily and naturally arise. Medicine is not an exact science, and the chances, therefore, for differences of opinion are the greater and the restrictions placed by law upon testimony are often provocative of the evils. He mentions the various methods that have been offered to mend the matter: The appointment of state experts; examination by the court; conference between experts, etc. He believes that the latter is the best method of obtaining agreement in such cases.

137. **Eye Diseases that the Practitioner Should Recognize.**—Among the special points which Rogers claims every practitioner should recognize in diseases of the eye are: The presence of foreign bodies, distinction between various phlyctenular types and diseases of the conjunctiva as distinguished from iritis, the diagnosis of iritis, of glaucoma, need of distinguishing refraction errors, etc. He believes that the more common affections should be treated by the general practitioner, though the more serious and complicated ones should be referred to the specialist.

138. **Appendicitis in Women.**—The following are the conclusions of Davenport's article: 1. Appendicitis is not so rare a disease in women as has been generally supposed. 2. On account of the smaller size and better blood-supply of the appendix in the female it is less liable to become so acutely inflamed as to call for operation, and, too, on account of the many diseases in the female with which appendicitis may be confounded, its true diagnosis is often overlooked. 3. In every abdominal section, for whatever purpose, it is absolutely essential for the best interest of our patients to examine into the condition of the appendix. 4. Appendicitis is frequently observed as a complication or extension of many of the pelvic disorders of women where it had not been suspcted prior to operation. 5. Appendicitis may be the cause of salpingitis or right-sided pelvic suppuration, but probably more frequently happens as a result or effect. 6. Chronic appendicitis is sometimes found to be the sole trouble in women of a neurotic temperament, when a previous false diagnosis of ovaritis or ovarian neuralgia has been made. 7. The differential diagnosis of appendicitis and the various diseases of women with which it may be confounded becomes comparatively easy if a complete history of the case is taken in connection with a carefully made physical examination.

The Lancet, July 14.

On the Confusion of Two Different Diseases Under the Name of Rubella (Rose-Rash). Clement Dukes.—From his experience the author concludes that two diseases are confounded under the general name of rubella. The second form represents a distinct condition varying slightly in the course of the eruption, which is more discrete at first and covers the whole body in the course of a few hours. The throat is more swollen and velvety in appearance, desquamation is more thorough, resembling in this respect scarlet fever, and the disease is not so infectious in the early stages as is rubella. He reports cases that he has observed, and concludes that while its resemblance to scarlet fever in many cases is close it can not possess any affinity with that disease, since both occur concurrently in the same epidemic, and some individuals have one disease following the other. Nearly one-half the cases in which this new type occurred had had the regular rubella within a year or two, which is not credible, according to Cullen's established law.

A Note on the Results Obtained by the Anti-Typhoid Inoculations in the Beleagured Garrison in Ladysmith. A. E. Wright.—This brief report of statistics of anti-typhoid inoculations in Ladysmith garrison shows there must be a real protection from the procedure. In the uninoculated the disease occurred in the proportion of 1 to 7.07, while in inoculated subjects it occurred in 1 to 48.7, and deaths in the two classes were in the proportion of 1 to 32 and 1 to 213, respectively. The proportions of deaths in those attacked were very nearly alike. Among the officers alone the figures were not quite so favorable, though still showing the proportion in favor of inoculation as compared to uninoculation. Wright is not certain as to the perfection of the inoculation given in these cases. In only two cases amongst those who had been twice inoculated was there any typhoid fever. Therefore, it seems that the double inoculation is a considerable additional protection. It may be possible that certain of the officers set down as inoculated may have been inoculated with anti-typhoid serum and not with vaccin consisting of sterilized typhoid cultures, and it is also possible, owing to the exigencies of military service, that they did not receive the full dose in all cases. He has found some instances where not more than one-fourth of the usual dose had been given.

Illustrations of Vasectomy or Obliteration of the Seminal Ducts Relative to Hypertrophy of the Prostate and Bladder Atony. Reginald Harrison.—The writer finds that vasectomy is equally effective and a very much safer operation than castration. The latter operation has in the aged sometimes produced serious trouble and occasionally is dangerous to reason and often to life. The operation of vasectomy causes, according to his observations, when performed in the manner prescribed in a previous paper, no untoward results whatever, and does not at all interfere with the internal secretion functions of the testicles, the absence of which is considered responsible for many of the effects observed after castration.

British Medical Journal, July 14.

The Importance of Post-Graduate Study. William Osler.—In this address Osler points out the advantages of post-graduate study and its needs amongst all classes of physicians. He thinks that the majority of us are apt to fall into the ruts of routine, hence the necessity of something to bring us out in contact with the progressive world, and the specialists are the ones that fall into the deepest ruts. No men need renovating more frequently than those who teach in schools of learning, the very dogmatic ways necessary to the teacher react upon him and intellectual staleness begins. In the conclusion of his lecture he speaks of the tendency to advance in the United States, and prophesies that English physicians of the twentieth century will find their keenest inspiration in the land of the setting sun.

Degeneration of the Neurone. Frederick W. Mott.—In this fourth lecture Mott dwells on the close relationship, etiology, and pathology of tabes and general paralysis, showing that in both the syphilitic poisoning is the original cause and in both there are juvenile hereditary forms. In his experience about 10 per cent. of cases of paralysis are associated with the tabetic cord lesions. In the one disease we have the disorder affecting the exogenous afferent spinal neurones, and in the other especially the neurones of the frontal and central convolutions of the hemispheres, but in both a similar process may take place. He reasons out the etiology of paralysis by assuming that it starts in venous congestion, which especially affects the portions of the brain involved. The following are the reasons advanced for considering it a primary degeneration of the neurone with secondary meningo-encephalitis. 1. Its relation to tabes. 2. The existence of the Argyll-Robertson symptoms in the majority of cases. 3. The existence of a gray atrophy of the discs more frequently than can be explained by mere coincidence, which can only be accounted for as a primary atrophy. 4. The evidence of wasting of the whole nervous system, affecting some parts more than others, but out of proportion to the evidences of inflammation. This must be primarily in the nervous system, for in no cachectic disease nor even in starvation do we find such extensive wasting take place. 5. Thickening of the pia-arachnoid membrane is proportional to and corresponds with the degree and locality of the atrophy, so it is with tabes. 6. In many cases the tabes, especially those with mental symptoms, atrophy of the tangential and superradial association fibers of the brain are found, quite similar to, but in different situations to those of general paralysis. 7. In cases of well-marked meningo-encephalitis, where there is no question as to its inflammatory nature, we do not find this extreme atrophy. As an example of efferent neurone degeneration he mentions amyotrophic lateral sclerosis, which must be due to some form of autointoxication. Peripheral neuritis is also discussed and questions of heredity in its relations to degeneration of the neurone, especially as illustrated by juvenile general paralysis, are also treated.

Annales de Dermatologie (Paris), June.

Anatomic Evolution of Syphilis. GASTOU.—Examination of the cadavers from Fournier's service during the last seven years has established that syphilis favors infections, especially hospital tuberculosis, cancer and various microbian associations. The anatomic evolution of the disease is shown to be, first a period of incubation, a silent interval extending from the inoculation to the appearance of the chancre, during which the pathogenic microbe of syphilis, leading a strictly anaerobic existence, produces lesions in the lymphatic system. The rare autopsies of syphilitic patients dying during this period, or as the chancre is first appearing, show these lesions predominating in the lymphatic system, and thus testifying to a general infection. The invasion period begins with the chancre and includes a second phase, the eruptive, a typical eruptive fever, whose anatomic localizations are on the venous system, and indicate that the pathogenic germ is a facultative anaerobe. This second, virulent, contagious period characterizes the disease essentially, and transmits it congenitally. It kills by cerebrospinal, hepatic or embryonal infection, and is cured by the specific, mercury. The third period is a true medical septic pyohemia, in which the specific microbe, its toxins and microbian associations focus on the arterial system all the energies of the disease. In this period the soil is more important than the germ. The disease creates an eruptive polymorphism which simulates any skin disease, and organic lesions which simulate those of any infectious disease. It is this period which begets degeneracy and malformations. It is characterized by infiltrations and scleroses, curable with potassium iodid. This conception of the evolution of syphilis and of the anaerobic existence of its microbe, indicates the importance of discovering a culture-medium for it which will reproduce the conditions of the lymphatic and venous systems in which it flourishes in the organism.

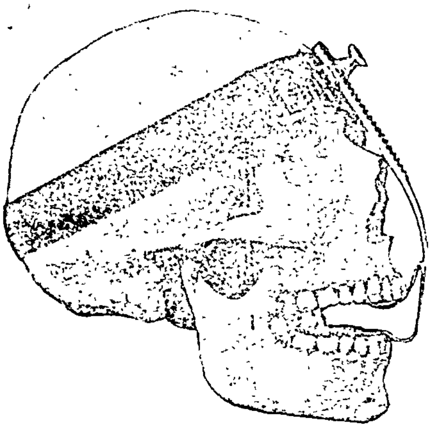
Annales de la Soc. Med.-Chir. de Liege, May.

Curvature of Head of Tibia in Fetus. A. BRACHET.—Scientists have always been much interested in the fact that the skeletons of pre-historic races show a backward curvature of the head of the tibia, apparently incompatible with an erect posture. Retzius has recently announced, and his statements have been confirmed by Brachet, that the tibia in the fetus invariably presents this anomaly, which changes to normal straightness during the first few months of life. It is more pronounced the younger the fetus.

Bulletin de l'Academie de Medecine (Paris), June 26.

Inhalation of Gaseous Antiseptics. P. LACROIX.—The principle of the inhaler invented and urgently recommended by Lacroix is the passing of a current of air through a mixture of .5 menthol, two to ten drops of bromoform, and five drops to twenty gm. of formic aldehyd, heated in an air-tight vessel, the patient inhaling the fumes generated. The microbicidal action was shown in tubes inoculated with pus, into which the current of air from the inhaler was turned for forty-five minutes, with the result that no cultures developed. Tuberculous sputa were also treated with the fumes for five hours and a guinea-pig was then inoculated with .5 c.c., with no effect on the health of the animal. The larynogoscope shows that there is no congestion of the tissues in the throat after inhalation of the fumes for therapeutic purposes, but the mucopurulent secretions of chronic laryngo-bronchitis dry up, and there is general relief and improvement in all pulmonary troubles. Bacillary ulcerations in the larynx become cicatrized; tuberculous laryngeal catarrh is healed, etc., while there are no inconveniences from the inhalations except a slight, transient sense of fullness in the chest at first.

Appliance for Anesthesia. A. REVERDIN.—The chief danger in administering an anesthetic is the possibility of arrest of the heart action by reflex action from the nasal mucosa. Reverdin causes his patients to inhale the anesthetic—preferably ether—through the mouth for this reason, and keeps it automatically open for the purpose by the simple contrivance shown in the cut.



Differentiation of Abscess in Cerebellum. DIEULAFOY.—Any otitis, acute or chronic, recent or even of forty years' standing, is liable to induce an intracranial lesion. As soon as the tympanum is infected, the pathogenic germs are liable to have their virulence enhanced under the influence of the closed cavity, as in the case of the appendix, and may spread thence in any direction. The cavities of the ear, including the mastoid cells, afford peculiarly favorable conditions for increasing the virulence of germs which have penetrated through the Eustachian tube, and the thin or porous bony walls offer but slight obstacle to their further migration, resulting in meningitic lesions, phlebitis or thrombosis, or an abscess in the cerebrum or cerebellum. The symptoms of the latter are generally cephalalgia, predominating in the occipital region, vertigo, ictus, loss of balance, staggering, vomiting, nystagmus, contraction in the neck, neuritis of the optic nerve, muscular asthenia, somnolence, torpor approaching coma, and possibly fever. This syndrome occurs, whatever the portion of the cerebellum involved, but paresis of the facial and external motor ocular nerves localizes the lesions on the same side. The violence, persistency and localization of the cephalalgia differentiate it from the aural or labyrinthic syndrome. The lack of motor disturbances, paresis, contractions and spasms on the side opposite the lesion, differentiate it from an abscess in the temporo-sphenoid or occipital lobes. Word-blindness and hemianopsia are also important symptoms of the latter. Tumors usually induce further symptoms, from compression of neighboring regions, and syphilitic lesions should also be carefully discriminated and receive specific treatment. Prompt surgical intervention, before the abscess has involved the adjacent tissues, is the only treatment applicable to abscesses of the cerebellum. Laborde exhibited in connection with this communication several rabbits which demonstrated the peculiar functions of the cerebellum as the "regulator of the equilibrium." A needle had been inserted in the cerebellum through the skull, inducing a strictly localized and circumscribed lesion, with the identical result for each point, in a large number of tests. Lesion of the middle peduncle induced a lively motor reaction, with loss of equilibrium, the animal turning rapidly on the lengthwise axis of the body, from right to left if the lesion was on the right side. Pricking the superior peduncle induced a motor reaction similar to the motion in circus-riding. Lesion of the inferior peduncle caused a deviation of the head and upper portion of the body to the side of the lesion. Frogs thus treated deviated invariably and irresistibly to the right in jumping and swimming. These three manifestations of loss of motor balance—due to lesions of these three points in the cerebellum, all closely connected with the innervation of the ear—easily explain the vertigo, etc., in an auricular lesion. The typical case of abscess in the cerebellum described by Dieulafoy was consecutive to an otitis a few weeks before, so slight that the patient had quite forgotten it. In entering the hospital he had been seized with sudden vertigo and had fallen violently toward the left. The abscess was found as diagnosed, in the left lobe, but not until the autopsy. The cerebellum appeared quite normal when exposed, and punctures missed the site of the lesion. The respiration suddenly ceased completely for twenty minutes, although the pulse could still be faintly felt at intervals. In exploring with his finger the surgeon touched the posterior surface of the medulla oblongata and immediately the patient made a deep and loud inspiration. Removing the finger respiration ceased again, but was resumed as soon as the finger was replaced and the patient was finally restored to life for a few days longer. The finger had probably lifted the pressure of the abscess from the respiration center in the floor of the fourth ventricle. The antero-external abscess was in the white matter, not encapsulated, containing about two gm. of creamy, greenish pus, with the pneumococus pure but not virulent. There was no other lesion.

Presse Medicale (Paris), July 4 and 7.

Tropical Fevers and Quinin. E. Legrain.—The conclusions of this study of 300 cases of tropical intermittent fevers in respect to their reaction to quinin, compared with that of non-intermittent pyrexias, show that a dose of quinin has no effect upon an established attack of intermittent fever, but that the proper amount—10 to 25 cg. —promptly administered at the first indications of an attack, will always cut short an intermittent fever for a minimum period of five days. On the other hand, all other pyrexias show the effect of quinin at once by an artificial and transient drop in the temperature, the amount varying with the disease and characteristic of each. In biliary affections and in septicemia of intestinal origin, the effect of quinin is disastrous, as it adds its own hemolytic action to the globulicidal action of the infection.

Resection of the Gasserian Ganglion. O. Jacob.—Attention is called in this article to the danger of injuring the sphenoidal sinus in resecting the Gasserian ganglion, with consequent infection and possibly fatal results. Jacob recommends the Krause-Hartley operation as less liable to injure the sinus than the pterygo-maxillary route, which he formerly advocated.

Semaine Medicale (Paris), July 4.

Immunity to Malaria. C. Firket.—The generally accepted idea that *malarial infection is a typical example of a disease which does not confer immunity against future attacks*, has been controverted by Koch's latest research, which tends to demonstrate that an immunity is gradually acquired in the course of time, and that whites can attain this immunity as well as negroes. This conflicts again with the experience of foreigners in tropical countries, who show an increasing mortality the longer their stay. Firket attributes this fact to the injurious influence of the climate, which hinders or prevents the colonists from benefiting by their acquired immunity. He, therefore, urges the necessity of diminishing this unfavorable influence by improving the general conditions of existence, especially during the convalescence from the first malarial attack—a critical period which may determine the degree of immunization and of ulterior capacity for work.

Berliner Klinische Wochenschrift, July 2.

Origin of Tuberculosis from the Blood. Aufrecht.—The fact that tuberculosis is not induced by inhalation of the germs seems to be established by Aufrecht's research mentioned in The Journal of July 28, p. 262. He has shown that the first stage of the tubercular process is a thrombus in one of the finer capillaries where the bacilli lodge, with consecutive thickening of the walls of the vessel and necrotic changes—caseous foci—in the portion of the tissue from which the blood-supply is thus cut off. He now announces that tubercle bacilli were invariably found in the thrombus or in the thickened walls of the vessel in both experimental and human tuberculosis in all his research, showing that they must have been derived from the blood. In one instance he found a pure culture in a thrombus in a tiny capillary leading to a single caseous nodule in the kidney of a rabbit. The discovery of the bacillus in these primary anatomic localizations offers a plausible explanation of all the varied phenomena of tuberculous affections in any part of the body in man or induced experimentally in animals.

Centralbatt f. Chirurgie (Leipsic), July 7 and 8.

Thyreoptosis. A. Kocher.—*It is more than probable that* many cases of thyreoptosis have been mistaken for asthmatic affections, and been vainly treated by internal remedies. The condition sometimes requires surgical intervention and Kocher has successfully operated on several patients. The gravity of the intervention is proportionate to the size of the displaced goiter, and consequently its early recognition is of great importance. An observation is described in which the only symptoms to suggest a hidden goiter were indications of slight paralysis of the recurrent and sympathetic nerves on one side. There were no signs of a goiter in the neck and the trachea was free its entire length. An elastic, deep goiter was palpated in the thorax, corresponding to an area of dulness over the upper half of the sternum and upper right ribs. It rose and fell in breathing, but caused no disturbance, as the thorax was large. The displacement in this case could be traced to an old, chronic muscular contraction, forcing the head forward.

July 14.

Etiology of Congenital Dislocation of Hip-Joint. P. Bade.—In twenty-five out of ninety-four cases of congenital dislocation of the hip-joint, Roentgen photographs showed more or less alteration of a similar nature on the sound side; the acetabulum unduly wide, the roof flat, the sides of the socket thickened, asymmetrical atrophy, or else anomalies in the growth of the head. Congenital dislocation is, therefore, due to a primary defect in formation, which may be so slight as not to induce dislocation. If the primary alterations are located in the upper portion of the neck and not in the acetabulum, coxa vara may result.

Deutsche Medicinische Wochenschrift (Berlin), July 5 and 12.

Traumatic Pancreatic Abscess. W. Strohmayer.—Two months after an injury in the gastro-abdominal region a workman, 43 years of age, presented symptoms suggesting an internal malignant tumor, not located in the stomach or intestines. There was no fatty diarrhea nor evidences of diabetes to direct attention to the pancreas, but frequent vomiting and increasing tympanism, icterus and cachexia were noted. The patient died in a sudden attack of intense dyspnea a month later, and the autopsy disclosed a perforation of an abscess in the pancreas into the pleural cavity. The trauma had probably induced a hemorrhage in the pancreas with subsequent abscess formation—Körte noticed a similar coincidence of trauma and abscess in three out of forty-six cases.

Spontaneous Rupture of Esophagus. Heintze.—The observation described resembled the twelve already recorded, except that there was no sensation of laceration and no subcutaneous emphysema. The patient was a mason, 43 years old, in vigorous health, although addicted to liquor; no antecedents. Immediately after a hearty meal he experienced a violent pain in the stomach, intensified by deep breathing, nausea, pulse 140, small, no fever, lungs free in front, heart sounds distinct, abdomen apparently normal. Death occurred in collapse seven hours later. A longitudinal perforation was found in the esophagus 1½ cm. long, 6 cm. above the cardia. The left pleural cavity contained 1½ liters of food from the last meal, the lung completely collapsed. There was no evidence of any abnormal processes to acount for the laceration.

July 12.

Immunity in Connection With Epidemics. A. Wassermann.—As the laws of epidemics and immunization are becoming better understood, they seem to establish that all infectiou diseasses—even malaria—confer immunity against further infection by the same microbe, the immunity varying in its intensity and permanence. Study of the recent small epidemic of influenza in Germany demonstrated that the influenza bacillus vanished rapidly and completely from the blood; this fact indicates a condition of immunity in the subject. But the additional fact was noted that the disappearance of the bacilli was followed by symptoms of intoxication;

the immunity only covers the live bacilli and does not protect against the toxins liberated by their dissolution. Koch and Donitz have suggested that the immunity conferred by an epidemic places a zone of immune individuals around an endemic focus which prevents the further spread of the infection until their immunity has lapsed. Wassermann found that every one of his patients in the recent epidemic of influenza had passed through a severe attack ten years ago. The immunity conferred by the latter had evidently not sufficed to prevent a new attack, but had caused the rapid destruction of the bacilli in the system, with consequent severe intoxication. He remarks that the recent slight epidemic is an indication that the populace is beginning to be ripe again for a new, extensive epidemic of influenza.

Staining of Malarial Parasites. R. Ruge.—The stain recommended in this communication is as effective as the usual ones, but dispenses with the necessity of a contrast stain. The "reds" are greenish, the "whites" bright blue and the different forms of the malaria germs almost black or dark blue. A solution of .2 soda in 100 c.c. water is heated, and as it boils .3 methylene blue pur. is added. The mixture is set aside to cool for forty-eight hours, when it is filtered ready for use. The amount of blue must be increased if the blood is over four weeks old.

Enucleation vs. Evisceration et al. H. Schmidt-Rimpler.—This communication from the Göttingen ophthalmic clinic was compiled with reference to the discussion of the question of the relative advantages of operations on the eye, announced for the approaching International Congress of Medicine. Enucleation was done 160 times, evisceration 149, and optic-ciliary neurectomy 26. Recovery was most rapid after the first and slowest after the last operation. In 4 of the 10 cases in which the eye was enucleated with existing sympathetic inflammation, it subsided in 4, leaving the sight good. Sympathetic serous iritis has a better prognosis than plastic iridocyclitis with extensive posterior synechiæ. Iridectomy in the latter case usually entails softening and loss of the eye, which without it may last a long time. Sympathetic ophthalmia is caused by a reflex irritation by the mediation of the ciliary nerves, and this irritation affords the disposition and a favorable soil for inflammation from any cause. This theory is supported by Moll's recent experiments with rabbits. He set up an irritation in the anterior chamber, with a fragment of copper introduced and then injected a culture of the pyocyaneus into the vein of the ear. The next day the microbes were found in the aqueous humor of both eyes, while none were found in either eye in control animals without a preceding injury. In one of the six case-reports which Rimpler adds to his communication, the sympathetic ophthalmia first appeared in the course of an angina. It may occur years after neurotomy or neurectomy or evisceration, by the growth of new fibers into the sclerotic. On the other hand, he has been frequently amazed at the way in which an eye that seemed ripe for enucleation has finally recovered without inducing sympathetic disturbance. When a condition of irritation in both eyes is evident, he treats it with mercurial inunctions or subcutaneous injections of sublimate, and a darkened room. He advises evisceration as the operation for non-specialists and in case of suppurative processes and also to prevent asymmetry in the development of children. The indications for optic-ciliary neurectomy are limited. It should never be done unless the danger of sympathetic disturbance is very slight, and consequently, never in case of a foreign body, nor of extensive defect of the eye.

Meningotyphoid Fever. A. Hofmann.—There is evidently a close connection between all the cerebral symptoms in typhoid fever, from the extremely severe manifestations in the observation described, with death in coma, to the convulsions, twitchings, trembling of the fingers, delirium or slight somnolence noted in others—all directly traceable to the influence of the toxins secreted by the typhoid bacillus and circulating in the blood. But when, as in the case reported, the bacilli penetrate into the meninges and thus bring the full strength of the toxin directly in contact with the nerve tissue, the effect attains its maximum. The unusually large spleen confirmed this conception of the syndrome; the patient died before a suppurative meningitis had time to develop.

Experiences with Light-therapy. H. Strebel.—Whenever a sweatbath is indicated, the electric-light baths accomplish the desired end without taxing the heart, and they seem to have a specifically favorable effect on cardiac and diabetic troubles. The combination of light and warmth in the incandescent-light baths proved especially effective in some cases of old, chronic diabetes, in which the sugar was reduced from 6.7 per cent. to .1 within four weeks. Neuralgia was favorably influenced—especially ischias—in many cases, by the "light-warmth" baths, never by the light baths alone, but the most striking effects were observed in cutaneous affections, ulcus cruris, acne, furunculosis, etc. One case of ulcus cruris which had resisted all treatment for two years began to heal in five days of "light-warmth" treatment and was completely cured in twenty. Finsen uses the cold light exclusively, but Strebel finds the combination of light and heat most effective, and sunlight through a hollow lens filled with a vitriolized solution, the cheapest and best source, whenever practicable.

Muenchener Medicinische Wochenschrift, July 3.

Bilirubin in Urine in Heart Disease. F. Ott.—The Salkowski test revealed the presence of bilirubin in the urine of patients with heart disease accompanied by an icteric complexion. It also showed that the elimination of bilirubin persisted after that of urobilin had ceased. Much albumin or hemoglobin in the urine, or ingestion of salol, etc., prevented the detection of the bilirubin.

Venesection in Heat Stroke. C. Klein.—A severe case of heat stroke, from the unusual work in the engine-room of a steamer, was proceeding rapidly to a fatal termination from increasing edema of the lung. The convulsions prevented artificial respiration and bathing; the pulse and breathing contraindicated chloroform, and there was no time to prepare an artificial salt solution for transfusion. Klein withdrew 220 gm. of blood, the effect of which was immediately beneficial. The pulse and respiration became slower and fuller in a few minutes; the convulsions gradually ceased, and the patient slept calmly for ten hours.

Venesection in Uremia. R. V. Hoesslin.—Two observations are reported in which life was undoubtedly saved by venesection. One was a case of croupous pneumonia, the crisis rapidly following the intervention. In the other case nephritis and severe uremia had induced cardiac insufficiency, which had in turn diminished the urine and aggravated the nephritic process. The immediate danger was relieved by venesection—the patient was too agitated for the contemplated transfusion of artificial serum—and digitalis was then administered, which by raising the blood-pressure rapidly put an end to the remaining uremic symptoms by increasing the urine. The congestive processes in the kidney were also relieved at the same time as the cardiac insufficiency, and under the influence of the improved circulation through the kidneys, the nephritic process soon healed.

Atropin in Ileus. Batsch.—Two more cases are reported in which severe ileus with fecal vomiting was successfully cured with two injections of .005 atropin. In another observation laparotomy had finally to be performed, but the influence of the atropin was evident, facilitating the operation and preventing gangrene in the incarcerated loop.

Inexpensive Thermostat for Bacteriology. K. Walz.—A simple, reliable and inexpensive oven for bacteriologic cultures is afforded by applying the principle of the thermophore to a small incubating apparatus.

Therapie der Gegenwart (Berlin), June.

Electric Treatment of Bladder Troubles. E. V. Tovölgyi.—Certain bladder troubles accompanying organic nervous affections are amenable to electrotherapy. Two observations are related in detail of the success of three weeks' treatment with electrization of the vesical sphincter and of the prostate through the rectum, putting an end to serious urinary troubles of many years' standing, in patients with syphilitic antecedents and tabetic symptoms, one a butcher of 47, the other still younger, a cabinetmaker, with symptoms of sclerosis in patches.

Pain-Soothing Effect of Roentgen Rays. L. Stembo.—The analgesic properties of the Roentgen ray are extolled by the writer, who states that he has cured 21 out of 28 cases of severe neuralgia by a few sittings, usually three, of three to ten minutes in length. The current was 16 to 20 volts, with about 1500 interruptions to the minute and spark 45 cm. long.

Oak-Bark Baths for Pemphigus Malignus. A. Baginsky.—Five complete recoveries in eighteen cases of dermatitis exfoliativa or pemphigus malignus foliaceus, Baginsky considers a good record for his method of treatment, which consists in a six to eight minutes' bath at 27 C., with 1 kilo of a decoction of oak-bark in the water. The patient is then wiped dry with cotton and dusted thick with a powder of equal parts of zinc oxid and talcum, renewed several times a day. He has recently treated a fourteen-day babe in this way with brilliant results. All other salves and fluids are rigorously forbidden and the results are incomparably better than he has ever attained before.

Sozoiodolates in Scarlet Fever. A. Baginsky.—The severe ulcerative necrotic angina in some cases of scarlet fever is favorably influenced by insufflating sodium sozoiodolate with equal parts sulphur, several times a day, which has proved a valuable local adjuvant, in Baginsky's experience.

Tidsskrift t. d. Norske Lægeforening (Christiania), July 1.

Pregnancy with Intact Hymen. H. Brodtkorb.—Summoned to attend an obstetric case, the writer found a well-developed woman, married a year before. The pregnancy had been normal to term, but the hymen was intact, with merely an opening .25 cm. in diameter. The urethra was very much stretched and had been used for coitus without consciousness of the error on the part of either husband or wife.

Brazil Medico (Rio Janeiro), June 8.

Medicinal Plants. R. M. Da Silva.—Two plants grow in the Espirito-Santo district where the writer resides, which have been used by the populace for generations. One is of the Lamiacea family, genus leonotis. It is called "poor man's quinin" and contains a bitter alkaloid which cures malarial and gastric affections and is of great assistance in washing clothes. It renovates the skin, making it delicate and satiny as that of any European *grande dame*. The other plant is of the Amaranthacea family, the "Gomphrena pohlu." The infusion of the dried leaves forms a delicious, aromatic drink, much used in rheumatic and syphilitic affections. Da Silva recommends it in place of tea or coffee. The popular name is *chapeo de couro*, while the leonotis is known as *herva macahé*, *lavadeira*, and *S. Fidelis*.

New Patents.

Queries and Minor Notes.

GOAT LYMPH CURE.

Salisbury, Mo., July 24, 1900.

To the Editor:—Please give us something in The Journal about goat lymph; its use, value. status with the medical profession, etc.

J. D. B.

Ans.—The Journal does not advertise the goat-lymph cure, because it sees no reason for placing any faith in it. Moreover, the methods and claims of those exploiting it are not such as commend it to thinking physicians.

A COMPOSITE PROFESSION.

Dr. Adam H. Wright, in his President's Address before the Ontario Medical Association, calls attention to the following advertisement, taken from a newspaper of Shakespeare's time:

> WANTED—In a family who have had bad health, a sober, steady person in the capacity of doctor, surgeon and man-midwife. He must occasionally act as butler and dress hair and wigs. He will be required sometimes to read prayers, and preach a sermon every Sunday. A good salary will be given.

It would be an interesting addition to the "ad" if it could be stated what was "a good salary" at that time.

COAL-GAS POISONING.

Flint, Mich., July 5, 1900.

To the Editor.—In The Journal for June 30, 1900, page 1678, I notice an article with the heading "Poisoning by Coal-Gas and Its Treatment." In this article we are told that methane or marsh-gas is the ingredient that produces the light in coal-gas. I wish to call your attention to the fact that marsh-gas when burned is easily recognized by its producing a pale-blue flame far inferior to olefiant gas in luminosity, and very much inferior to acetylene. The writer of this article is mistaken as to the illuminating properties of methane, as it is acetylene that makes the gas rich in light-giving qualities and not marsh-gas. Some of the coal gases contain the cyanogen vapors in the shape of uncombined hydrocyanic acid together with several chemical compounds not mentioned in this article, and a novice that would base a solution of a problem upon this article would not be on the right road to success.

O. Millard, M.D.

Ashton, R. I., July 4, 1900.

To the Editor.—In an article entitled "Poisoning by Coal-Gas and Its Treatment," in The Journal, June 30, the writer asserts that "asphyxia means suffocation," and therefore the term "asphyxiation" as applied to this condition is incorrect. He quotes from Mr. N. Wiley Thomas, proving that carbon monoxid is an impurity, which poisons the blood by uniting with the hemoglobin, thus rendering the latter incapable of taking up the necessary oxygen.

As to treatment, he says that experiments made by Dr. Darrah show that carbon monoxid, by excluding oxygen, causes a feeble pulse—asphyxia—while the respiration is increased in frequency and depth, thus that the above condition is caused not by a failure of respiration—apnea—or suffocation, but by failure of pulse—asphyxia. The proper term to use, therefore, is "Asphyxiation."

N. O'D. Parks, B.A., M.D.

Ans.—In the article on coal-gas poisoning, referred to by our correspondent, the statements concerning the formula and the luminosity of coal-gas were misleading. The word "formula," in reference to a chemical substance indicates that it has a definite and unvarying composition. Coal-gas is a mixture, not a definite compound, and therefore, the word "composition" would have been more applicable. Again, the composition of coal-gas varies according to the variety of the coal used in its manufacture, and the composition given therefore is only a typical one. In giving the composition, the article mentioned illuminants, ethylene, acetylene, etc. These are included in the illuminants and therefore are mentioned twice.

As to the luminosity of coal-gas, both the article and our correspondent are partly correct, yet neither has told the whole truth. Marsh-gas, as such, does not burn with a luminant flame, but when heated it becomes changed to acetylene, and is thus the principal illuminant. As to the appropriateness of the term "asphyxiation," we should not be too hypercritical. Asphyxiation originally meant pulseless, and as the lack of pulse is one of the commonest symptoms of suspended animation, the word has come to be used in reference to any suspension of vital phenomena.

The Public Service.

Army Changes.

Movements of Army Medical officers under orders from the Adjutant-General's office, Washington, D, C., July 6 to 24, 1900, inclusive:

H. Eugene Allen, acting asst.-surgeon, from Fort Sam, Houston, Tex., to Fort McPherson, Ga., to accompany Co. M, 15th United States Infantry, to the Philippine Islands, via San Francisco, Cal., and on arrival at Manila to report for assignment to duty.

W. Edson Apple, acting asst.-surgeon, from Fort Columbus, N. Y., to West Point, N. Y., to accompany Co. E, Battalion of Engineers, to San Francisco, Cal., and thereafter to return to his proper station.

Lewis Balch, major and surgeon, vols., leave for absence granted on account of sickness.

John M. Banister, major and surgeon, U. S. A., member of board to examine candidates for admission to the United States Military Academy, West Point, N. Y.

Charles N. Barney, acting asst.-surgeon, from Fort Edward, N. Y., to temporary duty at Fort Monroe, Va.

Peter W. Beckman, acting asst.-surgeon, from Alton, Ill., to the Department of California.

William C. Borden, captain and asst.-surgeon, U. S. A., leave of absence granted.

Wilmot E. Brown, acting asst.-surgeon, from Taylorville, Ill., to Denver, Col., to accompany troops from the Department of the Colorado to the Philippine Islands.

Charles B. Byrne, major and surgeon, U. S. A., from Plattsburg Barracks, N. Y., to San Juan, Porto Rico, for assignment as chief surgeon, Department of Porto Rico.

W. Earle Chapman, acting asst.-surgeon, from Cheboygan, Mich., to the Department of California.

Alpha M. Chase, acting asst.-surgeon, from Denver, Col., to the Department of California.

August von Clossman, acting asst.-surgeon, from Jefferson Barracks, Mo., to duty as attending surgeon and examiner of recruits at St. Louis, Mo.

Marshall M. Cloud, lieutenant and asst-surgeon, U. S. A., to proceed to San Francisco, Cal., to accompany the 1st U S. Cavalry, en route to Manila, P. I.

William H. Corbusier, major and surgeon, U. S. A., from San Francisco, Cal., to Washington, D. C., to report to the surgeon-general for instructions.

Joseph J. Curry, acting asst.-surgeon, to report in person to the surgeon-general for instructions.

William B. Davis, major and surgeon, U. S. A., member of a board to examine candidates for admission to the U. S. Military Academy, West Point, N. Y.

Samuel M. DeLoffre, acting asst.-surgeon, from Washington, D. C., to Omaha, Neb., to accompany the 1st U. S. Cavalry to the Philippine Islands, reporting on arrival at Manila for assignment to duty.

Charles H. Fischer, acting asst.-surgeon, leave of absence granted.

John S. Fogg, acting asst.-surgeon, from Columbus Barracks, Ohio, to Fort Myer, Va., to accompany a squadron of the 3d U. S. Cavalry to the Philippine Islands, and on arrival at Manila to report for assignment for duty.

Marion O. Fulcher, acting asst.-surgeon, to accompany the 3d Battalion, 15th U. S. Infantry, from Madison Barracks, N. Y., to the Philippine Islands, *via* San Francisco, Cal., and on arrival at Manila to report for assignment.

Leigh A. Fuller, lieutenant and asst.-surgeon, U. S. A., to report at Washington, D. C., for instructions while en route, under previous orders, from Fort Monroe, Va., to San Francisco, Cal.

Charles M. Gandy, captain and asst.-surgeon, U. S. A., member of a board to examine candidates for admission to the U. S. Military Academy, West Point, N. Y.

Lewis T. Griffith, acting asst.-surgeon, leave of absence granted, and relief from duty at Fort Preble, Me.; on expiring of leave to proceed *via* San Francisco, Cal., to Manila, P. I., for assignment.

John Van R. Hoff, major and surgeon, U. S. A., relieved from duty as chief surgeon, Department of Porto Rico, to report to the surgeon-general for instructions.

Francis J. Ives, major and surgeon, Vols., relieved from duty as chief surgeon, Department of Matanzas and Santa Clara, to proceed to New York City and report by telegraph to the surgeon-general for instructions.

David J. Johnson, acting asst.-surgeon, to accompany the 1st Battalion, 15th U. S. Infantry, from Plattsburg Barracks, N. Y., to San Francisco, Cal., and thereafter to return to his proper station.

Dryden H. Lamb, acting asst.-surgeon, from Owosso, Mich., to the Department of California.

Edward E. Lambkin, acting asst.-surgeon, from St. Louis, Mo., to the Department of California.

Harry R. Lemen, acting asst.-surgeon, from Upper Alton, Ill., to the Department of California.

A. N. Mahon, acting asst.-surgeon, leave of absence granted.

Henry C. Many, acting asst.-surgeon, from Honesdale, Pa., to the Department of California.

James G. McKay, acting asst.-surgeon, leave of absence from the Department of Santiago and Puerto Principe extended.

John S. Nagle, acting asst.-surgeon, from Chicago to St. Paul, Minn., to accompany troops from the Department of Dakota to the Philippine Islands, where he will report for assignment to duty.

Ralph W. Newton, acting asst.-surgeon, from Barre, Vt., to the Department of California.

Arlington Pond, acting asst.-surgeon, from Rutland, Vt., to duty at Fort Preble, Me.

William W. Reno, acting asst-surgeon from Detroit, Mich., to the Department of California.

Michael J. Rowe, acting asst.-surgeon, from Bridgeport, Conn., to the Department of California.

Ira A. Shimer, lieutenant and asst.-surgeon, U. S. A., leave of absence from the Department of Santiago and Puerto Principe extended.

Charles F. Smith, acting asst.-surgeon, from Whitehall, Mich., to Denver, Col., to accompany troops from the Department of the Colorado to the Philippine Islands.

Louis A. Spaeth, acting asst.-surgeon, from Jersey City, N. J., to the Department of California.

Charles H. Stoeckle, acting asst.-surgeon, from Philadelphia, Pa., to Denver, Col., to accompany troops from the Department of the Colorado to the Philippine Islands.

Lionel A. B. Street, acting asst.-surgeon, from Brookline, Mass., to the Department of California.

Harrison W. Stuckey, acting asst.-surgeon, from Columbus Barracks, Ohio, to Fort Myer, Va., to accompany a squadron of the 3d U. S. Cavalry to the Philippine Islands and on arrival at Manila to report for assignment to duty.

Isedor M. Unger, acting asst.-surgeon, from Warren, Ind., to the Department of California.

Francis M. Wall, acting asst.-surgeon, from Warren, Ind., to Denver, Col., to accompany troops from the Department of the Colorado to the Philippine Islands.

Charles Willcox, captain and asst.-surgeon, to proceed to San Francisco, Cal., to accompany the 9th U. S. Cavalry to Manila, P. I.

Henry E. Wetherill, lieutenant and asst.-surgeon, U. S. A., to duty with the 1st U. S. Cavalry en route to Manila, P. I.

Frank T. Woodbury, acting asst.-surgeon, from Philadelphia, Pa., *via* San Francisco, Cal., to Manila, P. I., for assignment.

Navy Changes.

Changes in the Medical Corps of the United States Navy for the week ending July 21, 1900.

Medical Director P. Fitzsimons, detached from the naval examining board, Annapolis, Md., and ordered to duty in charge of the naval hospital, Newport, R. I.

Medical Director H. J. Babin, detached from duty as president of the medical board of examiners, naval laboratory, Brooklyn, N. Y., July 25, and ordered home and to wait orders.

Surgeon L. G. Heneberger, detached from the naval hospital, Brooklyn, N. Y.

P. A. Surgeon A. M. D. McCormick, detached from the *Chicago*, and ordered to the *Montgomery*.

Asst.-Surgeon J. R. Whiting, detached from the *Montgomery* and ordered to the *Chicago*.

Asst.-Surgeon C. N. Fiske, detached from the navy yard, Boston, and ordered to duty with marines at San Francisco, Cal., and then to duty at the naval hospital, Mare Island, Cal.

Asst.-Surgeon J. H. Payne, Jr., detached from the naval hospital, Mare Island, Cal., and ordered to the Asiatic Station with the Fifth battalion of marines.

Pharmacist A. Prosperi, detached from the naval academy, July 21, and ordered home and to wait orders; retired from July 3, 1900, under th provision of section 1143, Revised Statutes, upon his own application after forty years' service.

Marine-Hospital Changes.

List of changes of station and duties of commissioned and non-commissioned officers of the United States Marine-Hospital Service for the seven days ending July 19, 1900.

Surgeon P. M. Carrington, upon expiration of sick leave of absence, to proceed to Point Pleasant, N. J., for special temporary duty.

Surgeon T. B. Perry, upon return of Surgeon McIntosh from leave of absence, to proceed to Wilmington, N. C., and assume command of the service, relieving P. A. Surgeon C. P. Wertenbaker.

P. A. Surgeon C. P. Wertenbaker, to proceed to Washington, D. C., preparatory to receiving orders to assume command of the service at New Orleans, La.

Asst.-Surgeon H. S. Mathewson, to proceed to Philadelphia, Pa., and report to medical officer in command for duty.

Asst.-Surgeon M. J. White, upon being released from duty at Philadelphia, Pa., to proceed to San Francisco, Cal., and report to medical officer in command for duty and assignment to quarters.

Asst.-Surgeon W. C. Hobdy, bureau order of June 27, 1900, directing Asst.-Surgeon Hobdy to proceed to Honolulu, H. I., revoked and directed to proceed to Savannah, Ga., and assume command of the service.

Asst.-Surgeon W. C. Billings, granted 15 days' extension of leave of absence from July 15.

Asst.-Surgeon D. E. Robinson, upon being relieved from duty at Memphis, Tenn., proceed to Seattle, Washington, and assume command of the service, relieving Acting Asst.-Surgeon Eagleson.

Asst.-Surgeon Carroll Fox, relieved from duty at Port Townsend quarantine, and directed to proceed to Dutch Harbor, Alaska, reporting to medical officer in command for duty.

Asst.-Surgeon W. A. Korn, upon being relieved from duty at Evansville, Ind., to proceed to Philadelphia, Pa., and report to medical officer in command for duty.

Asst.-Surgeon C. W. Vogel, relieved from duty at San Francisco, Cal., and directed to proceed to San Francisco quarantine and report to medical officer in command for duty and assignment to quarters.

Asst.-Surgeon B. J. Lloyd, relieved from duty at San Francisco Quarantine, Cal., and directed to proceed to Cape Nome, Alaska, and report to Asst.-Surgeon B. H. Earle for duty.

Asst.-Surgeon J. T. Burkhalter, upon being relieved from duty at New York City, to proceed to Mobile, Ala., and report to medical officer in command for duty and assignment to quarters.

Asst.-Surgeon G. W. McCoy, relieved from duty at St. Louis, Mo., and directed to proceed to San Francisco, Cal., and report to medical officer in command for duty and assignment to quarters.

Acting Asst.-Surgeon R. C. Craig, granted leave of absence for 7 days.

Acting Asst.-Surgeon A. G. Greenstreet, to proceed to Wilmington, N. C., and report to medical officer in command for duty and assignment to quarters.

Health Reports.

The following cases of smallpox, yellow fever, cholera and plague have been reported to the Surgeon-General, United States Marine-Hospital Service, during the week ended July 20, 1900.

SMALLPOX—UNITED STATES.

Illinois: Chicago, July 7 to 14, 2 cases.
Kansas: Wichita, July 7 to 14, 2 cases.

Louisiana: New Orleans, July 7 to 14, 11 cases, 3 deaths; Shreveport, July 7 to 14, 3 cases.
Maryland: Baltimore, July 7 to 14, 1 case.
Massachusetts: Fall River, July 7 to 14, 1 case.
Nebraska: Omaha, July 7 to 14, 2 cases.
New Hampshire: Manchester, July 7 to 14, 1 case.
Ohio: Cleveland, July 7 to 14, 29 cases.
Pennsylvania: Philadelphia, June 8 to 16, 1 case.
South Carolina: Greenville, July 7 to 14, 1 case.
Utah: Salt Lake City, July 7 to 14, 2 cases.
Washington: Tacoma, July 1 to 7, 1 case.

SMALLPOX—FOREIGN AND INSULAR.

Brazil: Bahia, June 2 to 9, 2 cases.
England: Liverpool, June 23 to 30, 5 cases; London, June 23 to 30, 16 cases.
France: Lyons, June 16 to 23, 1 death; Roubaix, May 1 to 31, 1 death.
Greece: Athens, June 23 to 30, 4 cases, 2 deaths.
India: Bombay, June 5 to 12, 12 deaths.
Italy: Genoa, June 8 to 16, 3 cases.
Mexico: Vera Cruz, July 1 to 7, 9 deaths.
Scotland: Glasgow, June 22 to July 6, 170 cases, 3 deaths.
Switzerland, Geneva, June 8 to 16, 1 case.

YELLOW FEVER.

Africa: Goree Dakar, May 30 to June 16, 3 cases, 2 deaths.
Colombia: Barranquilla, June 23 to 30, 9 cases, 6 deaths; Cartagena, June 22 to 29, 11 cases, 9 deaths.
Cuba: Havana, June 27 to July 4, 5 deaths; Santa Clara, June 26 to July 7, 7 cases.
Mexico: Cordoba, July 1 to 8, reported: Progreso, June 23 to July 8, 3 cases, 2 deaths.

CHOLERA.

India: Bombay, June 5 to 12, 72 deaths.

PLAGUE

Arabia: Aden, June 8 to 16, 3 cases, 3 deaths.
Australia: Sydney, June 2 to 16, 14 cases, 6 deaths.
India: Bombay, June 5 to 12, 117 deaths.
Japan: Osaka, June 15 to 19, 1 case; Shidzuoka, June 15 to 19, 1 case.

Change of Address.

Dr. Spencer P. Irvin, from 1157 S. 19th St., Philadelphia, Pa., to Freedman's Hospital, Washington, D. C.

Dr. J. Klein, from 4800 N. Clark St. to 530 Lunt Ave., Rogers Park, Chicago.

Dr. F. C. Kovats, From 640 Jackson Boul. to St. Joseph's Hospital, 360 Garfield Ave., Chicago.

Dr. L. W. Lewis, from 4702 to 4711 State St., Chicago.

Dr. J. P. McMahon, from Lincoln Ill., to 69th St. and Wentworth Ave., Chicago.

Dr. J. A. Patton, from 2271 Harrison St. to 1150 Sheridan Road, Lake View Station, Chicago.

Dr. J. A. Prescott, from Cottage Grove Ave. and 31st St. to 4303-4305 Berkeley Ave., Chicago.

Dr. F. V. Watson, from Roberts, Wis., to 4658 State St., Chicago.

Dr. D. S. Adams, from 617 Orleans St., Keokuk, Iowa, to 905 20th St., Rock Island, Illl.

Dr. J. A. Guertin, from 731, 63d Court, Englewood, Ill., to L'Erable, Iroquois County, Ill.

Dr. G. H. Just, from Sheldon to Broadwell, Ill.

Dr. D. H. Pelletier, from St. Anne, Ill., to Fowler, Ind.

Dr. C. C. Birney, from Nora Springs to Mason City, Iowa.

Dr. Thomas G. Duncan, from Victoria, Texas, to 219 E. 4th St., Owensboro, Ky.

Dr. S. D. Holstein, from Leland to Sicily Island, La.

Dr. M. C. O'Brien, from New York City to Lewiston, Me.

Dr. Robert Sattler, from Groton Bldg., Cincinnati, Ohio, to Biddeford Pool, Me.

Dr. J. Madison Taylor, from Philadelphia, Pa., to Bar Harbor, Me.

Dr. C. G. Vary, from 47 W. Michigan St. to 47 W. Main St., Battle Creek, Mich.

Dr. B. F. Simon, from 3298 Hoyne Ave., Chicago, to 546 Mississippi St., St. Paul, Minn.

Dr. J. H. Amerland, from 2737 to 2739 Chippewa St., St. Louis, Mo.

Dr. G. W. McCoy, from Bristol, Tenn., to U. S. Marine-Hospital, St. Louis, Mo.

Dr. W. E. Walker, from Waveland to Pass Christian, Miss.

Dr. E. S. Goodhue, from Piru City, Cal., to Kailua, N. Kona, Hawaii, H. I.

Dr. M. C. Butler, from 516 College Ave., Elmira, to 49 Bridge St., Corning, N. Y.

Dr. F. S. Pearce, from Philadelphia, Pa., to Massawepie, N. Y.

Dr. F. A. Scratchley, 151 E. 72d St., New York Cty, to Palenville, N. Y.

Dr. S. G. Grant, from 58 W. 56th St. to 2 E. 45th St., New York City.

Brooklyn Medical Journal, from 103 Court St. to 1313 Bedford Ave., Brooklyn, N. Y.

Dr. T. Hubbard, from 145, 22d St. to 44 W. Bancroft St., Toledo, Ohio.

Dr. R. Bellamy, from 210 W. 57th St., New York City, to Stereus Villa, Newport, R. I.

Dr. M. L. Parler, from Parler, to Wedgefield, S. C.

Dr. F. M. Gage, from Lucknow to Rhea Springs, Tenn.

Dr. J. W. Bounds, from Chambersville to Weston, Tex.

Dr. J. D. Wiltrout, from Eau Claire to Marinette, Wis.

THE JOURNAL OF THE
AMERICAN MEDICAL ASSOCIATION

61 Market Street : : Chicago, Ill.

Cable Address: "Medic, Chicago"

Subscription price: Five dollars per annum in advance

Postage in the United States and Canada, Mexico, Hawaii, Guam, Porto Rico, and the Philippines, free; foreign postage, $2.50. Subscriptions may commence at any time. Volumes begin with the first issue of January and of July.

MEMBERSHIP IN THE AMERICAN MEDICAL ASSOCIATION.

The qualifications for membership require that the applicant be a member, in good standing, of a state or local medical society entitled to send delegates to the annual meeting of the American Medical Association. A list of these societies will be sent on request. Applications must be accompanied with a certificate showing that the applicant is a member of a recognized society, and should be sent with the annual dues—five dollars—to the treasurer, Dr. Henry P. Newman, 100 Washington Street, Chicago. Members receive The Journal free. Subscribers to The Journal may become members of the Association without additional expense if they are members of medical societies recognized by the Association. Those desiring to have their names transferred from the subscription to the membership lists should send certificates as above, with a receipt for their subscription to The Journal, covering the current fiscal year.

FISCAL YEAR.

The fiscal year of the American Medical Association is from January 1 to December 31; and the annual dues paid by a new member cover only the fiscal year, no matter at what time of year the membership is obtained. Those who pay their dues and join the Association at the annual meeting in June, for instance, pay only for the fiscal year which ends with the December following, and the annual dues for the following fiscal year are payable the succeeding January, at which time the treasurer sends a statement to each member. Such members, however, are entitled to The Journal for the full year, even though the membership be not continued.

PAPERS READ AT THE ANNUAL MEETING.

"Every paper received by this Association and ordered to be published, and all plates or other means of illustration, shall be considered the exclusive property of the Association. . . The Board of Trustees shall have full discretionary power to omit from the published transactions, in part or in whole, any paper that may be referred to it by the Association or either of the Sections, unless specially instructed to the contrary by vote of the Association." (From Article V of the By-laws.)

NEWS.

Our readers are requested to send us items of news of a medical nature, also marked copies of local newspapers containing matters of interest to members of the medical profession. We shall be glad to know the name of the sender in every instance.

ORIGINAL PAPERS.

Articles are accepted for publication with the understanding that they are contributed solely to this journal.

COPYRIGHT.

Matter appearing in The Journal of the American Medical Association is covered by copyright, but as a general thing, no objection will be made to the reproduction of anything appearing in its columns if proper credit be given.

CONTRIBUTIONS TYPEWRITTEN.

It will be satisfactory to all concerned if authors will have their contributions typewritten before submitting them for publication. The expense is small to the author—the satisfaction is great to the editor and printer. We can not promise to return unused manuscript.

Half-tones, zinc etchings and other illustrations will be furnished by The Journal when photographs or drawings are supplied by the author.

ADVERTISEMENTS.

Advertising forms go to press eight days in advance of the date of issue. Therefore, in sending in copy, time should be allowed for setting up advertisements and for the sending and return of proofs. Advertising rates will be made known on request.

CHANGE OF ADDRESS.

In ordering a change of address it is important that both the old and new addresses be given.

REMITTANCES.

Remittances should be made by check, draft, registered letter, money or express order. Currency should not be sent, unless registered. Stamps in amounts under one dollar are acceptable. Make all checks, etc., payable to "Journal American Medical Association," except those for annual dues. These should be made payable and sent direct to the Treasurer, Dr. Henry P. Newman, 100 Washington Street, Chicago.

The Journal of the
American Medical Association

Vol. XXXV CHICAGO, ILLINOIS, AUGUST 11, 1900. No. 6.

Addresses.

MATERIA MEDICA, PHARMACY AND THERAPEUTICS.

ADDRESS OF CHAIRMAN.*

LEON L. SOLOMON, A.B., M.D.
LOUISVILLE. KY.

As I appear before you to-day, I am deeply moved by the honor which you conferred upon me one year ago, when you selected me to be your chairman. Then and until now, I have sought to be ever mindful of the obligation which the position brings, and, as in previous years, have held the welfare and continuous advancement of the Section constantly before me. It has been my pleasure to be intimately associated with this Section for several years, during which time I have attended the sessions of none other; for two consecutive terms I served as secretary, and to-day, having a feeling of close affiliation with the work before us, I can appreciate all the more the honor of being your chief executive officer. And just here, let me say, greater good would come, I believe, to the individual sections of the Association, did the men who read papers devote their whole time to a single section. Instead, and it does seem unfortunate, men—among them some of the best—are prone to run diametrically in the opposite direction, and are willing to prepare papers and to read them, and to take part in discussions, oftentimes before several and totally different sections. So far as my acquaintance with scientific members of the profession permits of a judgment, I know few men capable of the production of several essays in one year, the original matter in which shows sufficient research, investigation or observation records to make them worthy of a hearing, before different departments of the Association. In a large medical body like this, the greatest good can only come from individual effort, properly correlated, and so long as the present system prevails certain sections must necessarily remain dwarfs, while others flourish, and viewed as a whole, no department can attain to its fullest success under the present régime.

To correct this evil the following resolution, or a modification of it, is recommended: No member shall be permitted to read a paper before more than one section during any one annual meeting of the American Medical Association. As unfair as such a resolution, on its surface, and at first sight, may appear, I believe the best interests of the individual sections and of the Association as a unit would, in such wise, be subserved. Furthermore, it is recommended that a closer watch be kept over titles and abstracts of papers, in order that such papers be presented to and read before the section to which they properly belong. This would necessitate the enforcement of a resolution which was once offered and recently passed, I believe, compelling authors to send in abstracts of their essays in good time for such proper classification. Papers have been read before this Section, in years gone by, which belonged to the Practice of Medicine Section, and, because of the high standing of the latter, it is not at all uncommon for members to select it, and there read essays, the character of which at once places them in our Section. However, since we have come to occupy a more exalted position, it is a matter which gratifies us to see dignified and distinguished fellows of the Association less frequently guilty of offering this unintentional slight, in favor of our most worthy sister department.

The Section on Materia Medica is one of the youngest in the Association. And, because of its youth, as well as for other reasons directly to be set forth, in its effort to survive, many obstacles have been contended with. When first established, therapeutics did not belong to the Section. It can not be said that the alma mater has failed to manifest an interest in us. However, the many other offsprings had, for the most part, already reached hardy youth, if they had not attained the full vigor of adult life, before the Materia Medica Section came into existence, and their needs, their requirements were greater, their interests seemed to be more conspicuous than ours. Such being the case, we had, and no doubt it was best for us, to work out our own future. What this future was the present now indicates; what it will be in years to come remains yet for us to prove; and if we and our successors dared venture an opinion, basing it upon the accomplishments of the Section during her past, surely there need be no cause for concern. If we but follow in the footsteps and path of the faithful officers and members who preceded us, glowing success can not but surely come. Besides our youth, until very recently there has been a general feeling of distrust, shared largely by the entire profession, in matters pertaining to drugs and other medicinal agents, and especially to drug therapeutics. When we require an explanation for this distrust we see the reason at once in the greater interest which has centered and attached to diagnosis, to pathology, histology, bacteriology, and other laboratory branches during the past several decades. While the study of materia medica and therapeutics lagged, the profession was perfecting itself in other seemingly more important branches, and very few men were devoting their time and interest to the investigation of the actions and uses of drugs. During this time, even the large number of medicinal agents already at our disposal was neglected. Original research and investigation was, for the time being, almost unknown; when men, in past decades, employed a given medicinal article, it was often with an indefinite knowledge of the best preparation of that article to employ, or how that best preparation might be obtained; nor did the prescriber know the certain effect which a given dose of a given drug might be expected to afford, to say nothing of the diversified uses to which the drug in varying doses might be put. Powerful weapons in the hands of men who do not know how to use them are inclined to do harm as well as good; besides, they create fear and distrust in the minds of others who might employ them to better effect. Drugs and medicinal agents are the armamentarium of the physician; to him they are what tools are to the mechanic, he must know how to employ these tools, else they serve him poorly. This fear and distrust of drugs became a dislike; men reasoned that the materia medica was a failure, therefore refused to consider it. Under such circumstances it was no wonder that our Section could not gain caste. However, the very causes which gave us our backset—the consideration of the several laboratory branches occupying the professional mind to the exclusion of drugs and drug therapy—when these considerations had once been fairly concluded, paved the way for a better and more wholesome study of this, the loftiest end and highest aim of all medicine. I repeat, my colleagues, the subjects which this Section has the honor and glory to study and consider, the questions upon which these essays of ours are written and upon which expressions of opinion are ventured, the matters which are discussed before this body—all these things belong to the department of medicine, which, as Fothergill has said, represents the highest aim and end, the loftiest attainment of all medicine. Without materia medica, deprived of therapeutics, using this word in its largest sense, what would the science and art of medicine be? The answer is so easy—nothing. The treatment of the sick, the healing of the wounded, the relief from pain and suffering—these things give medicine its great claim and make it the grandest and most divine gift of an all-knowing, all-kind and all-merciful God.

---

*Presented to the Section on Materia Medica, Pharmacy and Therapeutics, at the Fifty-first Annual Meeting of the American Medical Association, held at Atlantic City, N. J., June 5-8, 1900.

Our materia medica and therapeutics is builded upon the foundation of all the knowledge afforded by the laboratory branches. For its proper construction and appreciation a thorough conception of anatomy, physiology, histology, pathology, bacteriology, botany, mineralogy, pharmacy, chemistry, heat, light, electricity and other allied forces is now-a-days presupposed; and those who would then wield the medicinal agent to its best advantage, accomplishing with it the maximum of good with the minimum of bad, must have also mastered the larger subject of clinical medicine and clinical disease. Indeed, materia medica, and more properly therapeutics, is the "superstructure" builded upon all medicine. I congratulate you, then, gentlemen, upon your affiliation with this Section of the Association. I congratulate you upon being present at this, the fifty-first meeting, and I extend to you a hearty welcome to our proceedings during the next four days. I trust we will have a full attendance. A glance at the names which grace our program and the titles which have been selected by the Fellows who will read papers, to say nothing of the names of the gentlemen who will take part in the discussions, is sufficient to guarantee the success of this meeting. In the name of the Section, I desire to thank these gentlemen for the spirit which characterized their willingness to take part in our proceedings. They have done us an honor and we appreciate the compliment. The thanks of the Section are also due our worthy secretary, by whose diligent efforts, and to whose conscientious and painstaking devotion to all the ardous duties of his office, is due the completeness of the program. And now, gentlemen, in accordance with Section 2 of the by-laws, which says, "The Chairman of each section shall prepare an address on the recent advances in the branches belonging to his section, including suggestions in regard to improvements or methods of work, as he may regard important," etc., I beg your indulgence while I briefly review the several conclusions which the year's work with serum vouches. And by way of explanation, for the selection of such a topic, I would say the preponderance of positive testimony in favor of the usefulness of this class of medicinal substances demands that a closer study be made by investigators, in order that a better understanding of the whole truth be had, than is the case to-day. In the calling of attention to this necessity, and in the stimulation of profounder research, I trust a consideration of this subject by your chairman, this afternoon, will result. The study of certain so-called specific diseases, namely, those where the specific, etiologic factor is known, has, first in the laboratory, and then at the bedside, led to a study of specific medication. There are to be found, on the market to-day, and in more or less general use, the following articles, belonging directly or indirectly to the so-called class of serums or antitoxins: Diptheria antitoxin, tuberculin (old and tuberculin T. R.), antipneumococcus serum, antistreptococcus serum, antirabic serum, toxins of erysipelas and bacillus prodigiosus, yellow-fever serum, and vaccination against smallpox. To a brief consideration of the present status of these, I invite your attention. But, before we undertake their separate consideration, a general word seems proper. Immunity or resistance against intoxication and infection is of two sorts: natural and acquired. Acquired immunity may be active or passive. The production of active immunity consists in the graduated use of dead broth-cultures of poisonous bacteria in the lower animals or fowls. The resultant blood-serum has both antitoxic and anti-infectious (germicidal) qualities. When the immunization is brought about by the use of dead bacteria alone, freed from their adherent toxins, the resultant serum is germicidal only (anti-infectious) but not antitoxic, viz., will not neutralize toxins. In active immunity, we have a perfect example of the *vis medicatrix naturæ.* Passive immunity represents the employment of serum from such actively immunized animals or fowls, which is more or less rich in so-called antitoxic units. A unit of antitoxin is an arbitrary quantity, depending entirely upon the quality and concentration of the serum. In diphtheria, for instance, one unit has been selected to represent the amount of antitoxin which will protect a guinea-pig against one hundred otherwise fatal doses of concentrated diphtheria toxin. Clinical observation has, however, demonstrated that the curative dose of antitoxin must be much larger than the passive immunity dose. Among the theories which have been advanced to explain the action of immunity, "Ehrlich's Side-chain Hypothesis" is now the most generally accepted. Based upon a chemical theory of poisons attacking cells, it applies an accepted biologic principle—that of "functional hypertrophy." Ehrlich assumes that the reaction which follows the application of a bacterial poison, rendering the molecular side-chain functionally useless, results in the production, by the nutritive process within the nucleus of the cell, of an excess of side-chain radicles, and this excess, which is far beyond the immediate needs and requirements of the cell, leaves it, and, in the circulating fluids of the body, is an antitoxin. It must be remembered that certain portions of the body contain cells whose existing side-chain radicles are especially susceptible to the action of a given bacterial poison; thus, for instance, the central nervous system contain cells whose side-chains are susceptible to the action of the toxin of the bacillus tetanus; the toxin of diptheria affects the side-chains of bone marrow and of lymph-adenoid tissues. At the same time, it is readily proved that these same susceptible tissues often exert an immediate antagonistic action on bacilli and toxins; for example, place a virulent culture of the bacillus tetanus, containing toxic products, in an emulsion of fresh brain and it will be seen that the toxin is more or less neutralized—another instance of the powerful force of our so-called *vis medicatrix naturæ.*

DIPHTHERIA ANTITOXIN.

The action of this serum is so positive and the consensus of opinion is so nearly identical, regarding its usefulness, that little need be said in a résumé like this, regarding its value. The general rules which can be laid down to-day regarding the serum, are as follows: The more potent grades of antitoxin are superior to the weaker ones. A dose of 2000 or 3000 or 4000 units is advised for a severe case of diphtheria in an adult, or even 4000 for a very severe case in a child past three years of age, to be repeated in twelve hours if necessary, and a third dose—infrequently a fourth dose—is permitted in exceptional cases; 1000 units is employed in a mild case, if seen early, or 2000 in a mild case seen late. Babies under six months of age had best never have over 1500 to 2000 units, but in all cases the character of the disease more than the age regulates the size of the dose Behring's first statements regarding the immunity from antitoxin are now abundantly proved; namely, it is of little or no value to give even large doses of the serum in severe cases of diphtheria, well advanced. When the side-chains of cells are once overwhelmed by very virile toxins of diphtheria in *great* quantity the nutritive forces within such cells are unable to produce the necessary excess of side-chains to antagonize these toxins; therefore the patient succumbs. The greater success of the antitoxin of diphtheria over other antitoxins or serums for other diseases is due to the fact that all of the chemical poisoning or poisonings, the result of the life-growth and propagation of the bacillus diphtheriæ, are neutralized by the diphtheria antitoxin. The result of a given dose of this antitoxin on the diseased process is considered as about as follows: Symptoms grow less intense, gradually abating; the swelling and congestion lessen, and the local disease does not extend. How unfortunate it is that the same can not be said of tuberculin nor of the antipneumococcus serum. As an immunizing agent, the action of the antitoxin of diphtheria is, if we will except vaccination, without a parallel in the history of medical science. The writer recalls no instance,in his 1895-96 experience in the children's wards of several eleemosynary institutions in Berlin and Vienna, where a single case of diphtheria developed after exposure, providing the immunization dose of antitoxin was administered. Recently, the New York Department of Health published its records of over 6500 children, observed during a period of five years just ended, in whom such perfect immunity had been secured by antitoxin that only in twenty-eight cases did the disease develop, after exposure, and, among these, there were no deaths, we are informed, except one complicated by scarlet fever. Immunity is said to last about two weeks, but it was our custom, in 1895 and 1896 to administer other immunization doses, even within one week, providing a fresh exposure seemed to necessitate it. No harm, as a rule, other than rashes, passing joint inflammations and more or less fever occurred, and these were not permanent. Genuine scarlet-fever rash is sometimes closely simulated by this eruption, and, no doubt, scarlet fever has at times actually complicated, when the serum received the blame for the eruption. It is now attempted by an, as yet arbitrary selection of certain horses to avoid the production of this rash, and some of the laboratories are careful not to dispense serum which experience or experiment has shown will produce a rash —it having been found that certain horses will supply serum capable of provoking an eruption at one time, whereas other serum, obtained from the same animal at another time, has no such effect. These efforts, on the part of the manufacturer, oftentimes necessitating the casting aside of more or less considerable quantities of serum, otherwise very potent, and meaning to him a large pecuniary loss, are, to say the least, very commendable from a humanitarian standpoint. Such losses necessarily render more costly the better serum supplied, but this only demonstrates the wisdom and value of choosing the best, always. Chemical antiseptics, in small quantity, are permissible in a serum, but no serum should be offered for sale over the counter that is as old as six months.

TETANUS SERUM.

In the agent which is supplied us to antidote tetanus we have another seemingly powerful article, which, except for the fact that the latter disease can only be demonstrated after clinical symptoms manifest themselves, and not early in the stage of the disease, would, it is thought, yield a percentage of cures in a measure comparable to diphtheria antitoxin. But by the time clinical symptoms have manifested themselves in tetanus, the accumulated toxins have already brought about, as a rule, much harm in the susceptible side-chains of cells, in the central nervous system. When, if ever the time comes, tetanus shall be diagnosed early, as from the local wound appearances, which may at some future day be considered sufficient to make a diagnosis, then good may be expected from the serum which we are taught now is its complete antidote.

ANTIPNEUMOCOCCUS SERUM.

The germ which causes the disease, pneumonia, is distinctly a producer of septic poison, and the patient who succumbs to pneumonia most frequently dies because of the action of the septic material in the blood exerting its destructive influence on the special center of circulation. The pneumococcus differs from a bacillus, which, like the diphtheria or tetanus micro-organism, produces localized foci of disease from whence toxins are absorbed into the system, the bacillus itself not invading the general circulation and tissues of the body as a rule. Now, the pneumococcus does enter the circulation and it produces general bactericidal, septic poison. To-day, it is almost the consensus of opinion that it devolves upon the leucocytes to deal with this foreigner. The action of leucocytes, under such circumstances, on the pneumococcus, is described as a destructive one by a process of "engulfing," and it is explained, that the power of a given leucocyte to engulf pneumococci is largely increased by the antipneumococcus serum. In this wise, the tendency to intense septic poison is limited. However, the several varieties of serum, as now prepared from the human species, the turkey, the dog or the rabbit, have not, as yet, been found to possess any other merit, except in isolated cases, than this controlling influence on the septicemia. In order to be called genuinely useful, antipneumococcus serum must control the extension of the local process in the lungs, it must shorten the duration of the disease and bring about a prompt crisis. And since these accomplishments can not, as yet, be accredited to the serum supplied us, we must refuse to give it, in its present unfinished state, the certain place which, by fulfilling requirements, it may some day deserve. To this end, that it may come to meet, if possible, all the requirements of a perfect antagonist and antidote to this dread disease, further investigation and research must be continued.

TUBERCULIN.

Tuberculin, old, and tuberculin T. R., are of undoubted value. As a diagnostic agent, old tuberculin, employed in man as well as animals, has accomplished much. Koch's assistant, Brieger, asserts that failure, with old tuberculin, in the treatment of tuberculosis, may be and no doubt is sometimes due to the carelessness with which cases have been selected for its use. The bacillus tuberculosis manufactures, during its development, several poisons, and, at certain stages in the progress of this development, it is possible to antagonize the existing toxins, in the system, by tuberculin. However, at present, all of the toxins produced by this disease germ are not known, and unfortunately neither old tuberculin nor tuberculin T. R. is the perfect antidote to all of them. In lupus, it is proved now that old tuberculin and tuberculin T. R. are both curative. But, until we have a better knowledge of this particular department of therapeutics, we must consider it still in its experimental stage, and in the management of a selected case of tuberculosis, where either agent is tried, we should not lose sight of the value of foodstuffs and of other reliable medicinal substances to be conjointly employed in our plan of management. Surely, it must be said that an agent like tuberculin is deserving of some place in our materia medica and therapeutics, if, in exceptional cases, it seems to act well. In those, in whom cures are said to have resulted, and where tuberculin, in conjunction with other remedial agents, has been used, it is asserted that the patient remains, as a rule, in better condition than in other so-called cures, where tuberculin has not been used. And just here let me emphasize another valuable feature of such an agent, which, like tuberculin, permits us to feel more confident of a "sure cure" in those cases where the patient no longer shows signs or symptoms of disease. I refer to the propriety of using tuberculin as a diagnostic agent in our so-called cured cases. If no reaction takes place, following the use of tuberculin under such circumstances, we can feel more certain about the safety of the patient, and consider that a real cure has been effected.

ANTIRABIC SERUM.

The "Pasteur preventive inoculations," for rabies, lose their value, if symptoms of the disease have once developed. They are only of service as preventive inoculations—in the modified sense of immunity. Tizzoni and Centani have lauded the influence of their "antirabic serum." But several points in their procedure are open to criticism and lay the effectiveness of their serum open to doubt. Therefore, this antitoxin has not yet found a place, notwithstanding the good reports of the two above-named gentlemen. In their hands, it has been used in conjunction with Pasteur's preventive inoculations and this fact also modifies the seeming value of their "results."

TOXINS OF ERYSIPELAS AND BACILLUS PRODIGIOSUS.

The mixed, unfiltered and very virulent toxins of a culture of streptococcus erysipelatosus and bacillus prodigiosus are being used by several investigators, with undoubted results, in spindle-celled sarcoma. The dose of one-half minim, thrown directly into the tumor, is employed. Dr. Coley has had very satisfactory results in a sufficient number of cases to give to this plan a place. He reports it to be much less useful in the small round-celled tumor and still less in the melanotic.

ANTISTREPTOCOCCUS SERUM.

The consensus of opinion is, that, in genuine streptococcus infection, viz., where not only undoubted clinical symptoms of streptococcus infection exist, but where the germs may be demonstrated, as well in the urine sediment and in the blood as in the wound discharges, little or no good results from the use of the serum. Notwithstanding this fact, it has been employed by some with seemingly encouraging results. Urticaria infrequently follows its administration. The dose of antistreptococcus serum is twenty cubic centimeters.

It is needless for me, in this résumé, and at this time, to add to the already abundant literature on the value of vaccination against smallpox. Besides, time forbids, and I hasten to call your attention to a subject of greater and far more vital interest and importance to the Section than anything else, I believe, which, as your chairman, it is my duty to introduce. And, in offering this subject to you to-day, gentlemen, for your consideration, I am not unmindful of the fact, that in the opinion of some men, and possibly in the opinion of some of those present this afternoon and within hearing, it would be considered both the part of wisdom and of valor, as well as proper and politic, to dispose of the matter best, by at once dropping it and ignoring entirely the source of its origin. This was my intention at one time last year, when first the question arose, and notwithstanding the fact, that the brunt of the attack then fell on me, because I was your chairman, I had decided to pay no attention to the blasphemy and insults heaped upon us, since they came from a source whose private monetary interests were calculated to make them take an unfair and partial view of the situation; and more especially, since those who preferred charges, and very recently have reopened the attack, were entirely *outside* of the profession. I am calling your attention, gentlemen, to the exceptions taken last June, after our adjournment in Columbus, by some of the interests of that institution known as "proprietary medicine." The Section had elected its officers, then, as usual, had appointed delegates to the Pharmacopeial Convention, had appointed its several committees and had transacted other business before it, in a regular, routine way. But it would appear from communications which began to reach my desk soon after that neither the election, the appointments nor the other business transacted was in keeping with the hopes and the wishes or desires of certain manufacturers. The fact that the Section had gone on record a year previous, at the Denver Meeting, and again at the Columbus Meeting had fixed its seal of disapproval on papers exploiting nostrums was seemingly sufficient grounds for the "outsiders" to begin then a secret attack, which more recently they have been audacious enough to wage openly against us. I have letters with me which they have circulated, setting forth from their own standpoint a "strong case." With the contents of these, it seems, you should be made familiar. I shall place them here on the table, for your perusal, and you can then deal with the matter as your judgment directs. However, as your chairman, and being in possession of all the facts, I feel it my particular duty in advance to deny, for the Section, the truthfulness of these statements and accusations. It is not necessary for me to assure members of this Section that there is not now nor has there been, at least for the past several years, any foundation for the belief and the rumor that the Section would be "controlled" by those "allied" with any trade interests. The Section is officered now, I trust it may be said, and no doubt will continue to be in the future, by those who have the lofty interests of scientific medicine at heart. Such was not the case at one time, when the Materia Medica Section of the American Medical Association was the instrument of commercial interests and the organ of such of the proprietary medicine trade as was able to control it. Finally, gentlemen, I commend for your action not only the consideration of this subject, but also refer you to the other recommendations made, and have reason to feel assured that the Section will express, in no unmistakable terms, its feelings, by the course which it will pursue and by the policy which the future will see it develop.

SECTION ON OPHTHALMOLOGY.

ADDRESS OF THE CHAIRMAN.*

H. V. WÜRDEMANN, M. D.

MILWAUKEE, WIS.

The Chairman of the Section on Ophthalmology has but little to say this session, beyond welcoming you to the meeting and making some comments upon the program and plans prepared for our deliberations.

The officers have adhered strictly to the instructions given by the last session, having accepted the prescribed forty papers from the considerable number offered. It seems to me that this plan of procedure, involving as it does a careful selection, while it makes the duties of your officers more onerous, will give the most satisfactory program. We are the representative body of American ophthalmologists, and should not waste our time by unprofitable discussions or on definitely decided diseases or methods of treatment. Our deliberations should be *fin de siècle* and upon new or unsettled subjects, the results of original research. Opportunity is afforded at this meeting for the establishment of the authoritative opinions of American ophthalmologists upon two subjects connected directly with the manufacturing and transportation interests, and for forming a precedent which will sooner or later be brought up in our courts of law.

This plan of program formation and conduction for a medical meeting of this character is the culmination of a long-cherished idea. Three years ago I drew up a series of resolutions for the government of the program committee of the Wisconsin State Medical Society, and as chairman of that committee for the ensuing year had the satisfaction of seeing the number of papers reduced 50 per cent., while their character was increased by a like ratio, and our meeting rendered infinitely more profitable.

From this, or a similar germ, grew the suggestions made in the address of our esteemed presiding officer of last year, from which the seeds are spreading to other sections and to other societies. The method of limitation has thus far proved successful and time will surely show its practical value.

The suggestions of my predecessor, which met with approval by the Section, have been generally adopted by the present officers. There has been arranged one symposium for each day, with stated discussion, after which the subject will be opened for general debate. Those on the relations of visual defects to vocations; on the amount of injury to the business capacity of the individual from eye defects; on the absorption of ocular exudates, may be considered most pertinent and timely. It is very necessary in this country of vast railroad interests that there should be some uniform standard of visual acuity and ocular health established, by which the great corporations, who are responsible for the lives of each one of us for an average of several days in the year, should be able to select reliable employees.

The time has come when the public demands the utmost safeguards; and corporations have found that their efficiency has not only been increased, but vast sums of money saved, through a proper medical, and more particularly ocular, inspection of prospective employees. The damage to the individual from eye accidents is of great medicolegal interest, and a certain precedent for its estimation may perhaps be reached through our discussion of the subject.

The other papers offered seem to be of present interest and to surpass many of those of previous sessions. This is an evidence of material progress and should be deeply gratifying to all members of the American Medical Association, and to the Section on Ophthalmology in particular.

THE MEDICAL PROFESSION.

THE NECESSITY OF AND BENEFITS FROM ITS MORE COMPLETE ORGANIZATION.*

J. C. BIERWIRTH, M.D.

BROOKLYN, N. Y.

In selecting a subject for this address, it seemed to the writer that we might, with profit, turn aside from the well-beaten path of science, and consider briefly what necessity exists for, and what benefits may be derived from, more thoroughly organizing our profession. Recent events concerning this association have pointed out the directions in which we must look for improvements. We need not search very long, nor look very far, for there are many fields, almost barren now, but capable of the highest cultivation and holding out promises of the richest harvest.

Let us pause for a moment and look about us to see what other men, in all the other walks of life, are doing to protect their mutual interests. During the past twenty or thirty years, all professions, except the medical, have organized for mutual benefit. If these organizations had not been needed, or had not accomplished the purpose for which they had been formed, they would have ceased to exist.

Furthermore, these organizations were not made for pecuniary benefit only, but also to protect their members against unjust clients, to protect them when attacked and to aid them and their families in sickness and in death. That the results of this alliance have been more than satisfactory no one will deny. The professional men and women are better paid, and their rights are respected now, where formerly they were not, all of which has resulted in greater self-respect and bettered conditions in all directions.

Let us see how the medical profession compares with other professions in point of organization for mutual benefit. There is no lack of medical societies, "for the advancement of medical science and the maintenance of public health," but how many societies are there in this state, or in the United States, which go farther than this, which will protect their members against injustice and threatened losses of whatever nature? Not one, I venture to say. What is the reason for this? No one, I think, will deny the necessity for such an organization, and yet we have been going on, year after year, suffering indignities and losses without ever attempting to correct the existing evils.

---

*Presented to the Section on Ophthalmology, at the Fifty-first Annual Meeting of the American Medical Association, held at Atlantic City, N. J., June 5-8, 1900.

*President's address, delivered before the Sixteenth Annual Meeting of the Fifth District Branch, New York State Medical Association, May 22, 1900.

One of the main reasons for this is a lack of proper organization. There are too many medical societies in this state. The multiplication must of necessity increase the difficulties of closer organization, because it divides the interests instead of consolidating them, and makes it harder for the members to concentrate their energies for the common good. I do not wish to be understood as not favoring special and local societies; on the contrary, what I do wish to emphasize is that all members of our profession should unite their efforts to make the representative society of this state the center of their energies for the common welfare of the profession and public at large. If this is done, as I hope it will be, then we may soon see the time when the existing evils will disappear.

What are these evils by which we are beset? They are many and have been too long endured. First of all, is the lack of respect of the public for our profession, as shown by the constantly increasing number of malpractice suits without adequate cause.

Do you suppose that our State Legislature would oppose any measure which was sanctioned by the New York State Medical Association, representing, say, 10,000 physicians of this state; or that any individual would have the courage to sue his physician unjustly for malpractice, if the lattter's cause were defended by the medical associations of this state?

I doubt it very much. The experience of this association at Albany in regard to the legislative matters has always been that the legislature is ready, at all times, to grant proper relief if there is no factional opposition. It is a well-known fact that suits for malpractice are of almost daily occurrence, and, without doubt, more than 90 per cent. are for inadequate cause, and for blackmail only. It is too well known among a certain class of individuals, as well as among a certain class of lawyers, that doctors are an easy prey. They are sensitive, also, to their reputation, which must always suffer from suits of this kind; they abhor publicity, and are only too glad to compromise to prevent this and save trouble. But what a different state of affairs would exist if every unjust suit for malpractice were defended by our State Medical Association and if the people knew that they have to deal with a powerful society instead of a weak individual.

Another crying evil to be remedied is the indignity heaped upon a number of physicians every year, by having to suffer unjust arrest for a supposed criminal abortion. The occurrence of the past year, where two physicians were arrested for a case of this kind through the stupidity of a police official, is still fresh on the memory of every one. They were entirely innocent of the charge and had attended the woman as a charity patient because she was in need of medical aid. Such cases as this one should be resented by every medical man in the state and country, and we should see to it that repetitions of this kind are made impossible. If a law to effect this end is needed, it should be obtained without delay. If the officials know that to arrest a physician unjustly for a supposed complicity in an abortion case may be fraught with the gravest consequences for them, if they know that the medical association of the state will protect its members to the utmost against such outrages, then they will think twice before proceeding, and they will require more than vague suspicions or stupid deductions from the facts at hand before resorting to arrest.

The much-discussed abuse of medical charities is another evil which has existed too long, and which, it is to be hoped will be speedily remedied by the "Dispensary Bill," enacted last year through the efforts of this association. This dispensary evil had assumed such vast proportions that it threatened to seriously affect our profession.

Anotner evil which flourishes and needs speedy correction is the lodge or association doctor, who makes a yearly contract to treat the members of an organization for a few dollars a year. He can not do good work, because his work is cheapened and he has to work harder and faster in order to make both ends meet; and the patient is the sufferer.

The members of the council of this association, having recognized the need for correcting the existing evils, came to the conclusion that this could be done only by first organizing the profession of this state into a more harmonious whole, and that in order to be able to do this successfully more legal recognition was necessary. An endeavor was therefore made to obtain from the legislature of this state a charter which would confer all the requisite power. After a great deal of hard work on the part of our committee on legislation, especially its chairman, Dr. E. Eliot Harris, and also the different members of the council, our efforts were crowned with success, and we were granted, on April 14, of this year, a charter which will enable us to carry to a successful end all the proposed improvements in our association. This charter is the foundation upon which we may build a structure of any magnitude, without fear of overburdening its carrying capacity; but the erection of this building should be slow and deliberate and should be wisely superintended, lest we commit errors in construction which it may be difficult or impossible to correct later on.

One of its provisions is to the effect that the New York State Medical Association may form district branches and county associations. This forms the real foundation for its construction, upon which the superstructure may safely rest. By virtue of this provision, all members of the county associations become members of the state body, and thus increase its membership materially. The county associations of New York and Kings have already ratified the action of the council of the state association, and have added thereby to its membership about seven hundred members. It is purposed that each county in this state shall have its association, and these different county bodies be grouped under the now existing five branches of the state association. Each county and branch will then have its pro rata representation in the governing body of the parent association. It will thus be seen that each county will be represented with full voting power in all matters pertaining to the welfare of the association and its members. Believing in home rule to the fullest extent, it is thought best to have all members admitted to the association through the county bodies, because applicants for membership are best known in their own communities and their fitness for membership can be best determined there. It is further purposed to protect all members against unjust malpractice suits. If a member is sued, a committee, together with the counsel of the association, will investigate the facts in the case, and if convinced of the member's innnocence, the association will carry the case to its end, and will not compromise. Another protection which this association hopes to be able to afford its members will be in cases of arrest for supposed complicity in abortion cases. One case, fought to the bitter end with all the power and resources of our state association, will be sufficient to prevent many repetitions in the future. Let it be known that any one who assails the honor and dignity of a member of the New York State Medical Association assails the honor and dignity of all its members, and that all will rise in a body for the protection of their fellow, provided he is in the right. The creation of a death-benefit fund for the dependents of its members is another important feature in our new charter. There should be no difficulty in making this successful in every way. The details for it can not at present be outlined; they require much thought and care in their arrangement. But its success is assured if all members will lend their help and work for it. It should be no difficult matter to so arrange the finances of our association that we are able to pay to the family of each deceased member a sum of money that will insure to them all freedom from immediate want. What that sum will be is at present impossible to say.

Another advantage to the members of this association is the "Medical Directory of New York, New Jersey and Connecticut." It is a revival of the old "green book," published for many years by the late Dr. William T. White, under the auspices of the New York Medico-Historical Society, and now published by the New York State Medical Association. The first volume was issued in 1899, and the volume for this year is well under way and will be ready for distribution some time in August. Every member of this association receives a copy free of charge. The labor and care necessary for publishing this work has been stupendous and can not be estimated by any one unacquainted with its details; it would have been impossible, had it not been for the unselfish devotion of a few of our members, who were willing to give much of their valuable time, as well as money, for a good cause, and without expectation of personal gain. In order to make the directory as perfect as possible, the committee on publication need the aid of all the members of this association. Every one should keep a record of all the mistakes he finds, and promptly send them to the secretary of the committee for correction in the next issue; every one should encourage the advertisers by patronizing them, when possible, or by telling them that he has been pleased to have seen their advertisement in the directory. To obtain advertisements is hard work, and the financial success of the book is largely dependent upon them. The members can further aid by seeing that the book is in the hands of all who should have it, such as hotels, druggists, newspaper offices, etc., by asking for it, and if it is not at hand, offering to sell it.

In the foregoing I have endeavored to enumerate briefly the existing evils, to point out the ways and means for their remedy, and to outline the plan of the Council of this Association for a closer organization of its members. Our endeavor must be to produce an association of which all shall be proud, and in which membership shall be an honor, coveted by all! If every one will do his duty and give his aid, success is assured beyond a doubt, but all must be willing to set aside personal strife and personal differences for the common welfare of all. When we stand shoulder to shoulder, and present a solid front, none dare to assail us, and our friends will respect us. It is to be hoped that the example to be set by our State Medical Association will be followed by every other state medical association, and that the spirit of closer organization will pervade all state societies. It should then be the endeavor of the delegates to the American Medical Association to infuse this spirit into that body, and to produce a national association which shall be second to none and which shall have a controlling influence in all national affairs pertaining to public health and the science of medicine.

THE TREATMENT OF ACUTE ALCOHOLISM BY LARGE DOSES OF DIGITALIS.*

HENRY P. LOOMIS, M.D.
NEW YORK CITY.

Suggestions for the use of large doses of digitalis in the treatment of acute alcoholism came from Sweden and England. Fothergill and Jones, of Jersey, England, were the first to introduce its use to the medical profession. Both recommended it very highly. The latter publishes a report of over seventy cases treated by this method alone. He claims that he never saw any alarming symptoms following the use of one-half ounce doses of the tincture. A few clinicians in this country have tried the remedy with varying success; among them Dr. Horatio C. Wood, of Philadelphia, who speaks highly of its effect in a certain class of cases. It is interesting to note that a drug whose use even in moderately large doses is supposed to be fraught with some danger, can be given in one-half ounce doses without producing any of the ordinary symptoms of digitalis poisoning. Various explanations have been offered to account for the tolerance of these enormous doses. Wood believes that its explanation lies in the fact that the heart has become by long habit very much benumbed to the influence of stimulants, and explains the narcotic effect of the drug by the fact that the rest and sleep which follow its use are not the result of the cardiac stimulation, but are principally due to the increased flow of blood to the nerve-centers. Others have explained the effect to the digitalis controlling the arteries and compared its action to that of ergot in hemorrhage.

All investigators agree that in acute alcoholism there is singular tolerance of this remedy and the majority believe that it can be used in these large doses with but little danger. Ringer, in an extensive discussion of the subject, recommends it highly and closes his article with these words: "It remains to ascertain the form of the diseases amenable to digitalis."

While this remedy has been used quite extensively in England it has had no extensive trial, so far as I am able to ascertain, in this country. During the past spring, while on duty as attending physician to the alcoholic wards of Bellevue Hospital, I used the tincture of digitalis in one-half ounce doses in a series of ten cases of acute alcoholism. These were selected so as to include different classes of individuals—the strong and the robust, the weak and the anemic, the young and the old; those with nephritis and those with surgical complications. In treatment of those of delirium tremens a routine practice was followed. They were ordered one-half ounce of tincture of digitalis, to be given every four hours for three doses. If the patient became quiet and the delirium disappeared the remedy was stopped before the third dose. If not, another series of three doses six hours apart was ordered.

---

*Presented to the Section on Materia Medica, Pharmacy and Therapeutics, at the Fifty-first Annual Meeting of the American Medical Association, held at Atlantic City, N. J., June 5-8, 1900.

In the cases that showed the best results not more than three doses were necessary. The guide to the repetition of the dose was its narcotic effect. No marked dropping of the pulse was noted in any of the cases, but in the successful ones the pulse was seen to be increased in force, and to become fuller, stronger, and more regular after the first dose. The cold clammy perspiration disappeared, the skin became warmer, and the patient went to sleep. No effect of the remedy was noticed on the kidneys as shown by the usual secretion of urine.

In only three cases of the ten was the result so pronounced and so quick that there seems to be no question that it was entirely due to the effect of the digitalis. In some of the cases the remedy was an absolute failure. Two died; in both autopsies were made. In one no lesion was found beyond the wet brain of acute alcoholism. In the other case, which died in convulsions, besides edema of the brain, petechial hemorrhages were found beneath the endocardium. I have always felt that possibly in this case the digitalis had something to do with the cause of death, although it was a desperate case complicated by acute articular rheumatism. Still the man was a robust individual 30 years of age.

The following case is one of those in which the digitalis shows its most beneficial effects: A young man, well nourished, robust, 22 years of age, entered the alcoholic wards late one afternoon, showing all the symptoms of a severe delirium tremens of two days' standing; temperature 101, pulse 102, respiration 24. He was ordered during the first night one-half ounce of tincture of digitalis at nine, one, and five. He slept none during the night and had to be restrained. The next morning at 9 o'clock the temperature fell to 99.5, pulse 100 and respiration 24. The patient became quiet, delirium disappeared and he went to sleep. He slept all that day with the exception of about three hours, when he had to be restrained. He received no more digitalis, and during the next night his sleep was unbroken. The following day he was perfectly rational, and in the afternoon left the hospital. Ordinarily such cases, even under the best treatment, are not discharged before three or four days.

The second of the successful cases was a man of robust build, 32 years of age, who entered the ward with alcoholic delusions. After twenty-four hours he developed delirium tremens and had to be restrained. In twenty-four hours more the ordinary treatment of narcotics was followed, with no effect—temperature 103.2; pulse 108, respiration 30. He was put on tincture of digitalis, half-ounce doses every four hours. After four doses his temperature was 99.4; pulse 106; respiration 24, and he was quieter but still delirious. A second series of three half-ounce doses of *digitalis*, each four hours apart, was ordered. After the second dose the patient went to sleep and slept almost continuously for twenty-four hours. He left the hospital the following day.

It is needless to report the other cases in detail, but as a result of studying the carefully kept records of these cases and from my personal experience in the use of the drug a year ago in six cases, I would state the following as my conclusions:

1. The indiscriminate use of large doses, half-ounce, of digitalis in acute alcoholism, is fraught with danger. 2. The cases in which it should be given are the strong, robust, those in early life, with no complications, and those with violent delirium. In these cases the result, I believe, will be exceptionally favorable. They become quiet, go to sleep with a certainty and promptness that is obtained by no other methods with which I am familiar. 3. If after three doses no narcotic effect is noted, I would not advise a continuance of the remedy. I believe in the above class of cases it can be used with perfect safety for a limited number of doses. 4. The failures among my cases were in the chronic alcoholic subjects, in those in middle and advanced life, in the anemic, and in those with bad nutrition. 5. One fact noted which showed marked results from the treatment was that when the patients recovered and awoke from their sleep they were in such good condition that they were able to leave the hospital at once. This is an unusual experience, as ordinarily convalescence is delayed for two or three days.

Note.—I am indebted to my house physician, Dr. Metcalf Polk, for assistance in obtaining the above information.

DISCUSSION.

Dr. O. T. Osborne.—It is a question whether such large doses of digitalis are entirely safe in all cases of acute alcoholism. I think that we ought to be very skeptical about adopting the doctrine that the action of a drug is so very different at one time from what it is at another. The condition is probably such that the drug is not absorbed.

The absence of the usual effects following the administration of these large doses of tincture of digitalis may be explained by assuming that the condition of the patient, suffering with acute alcoholism, is one resembling shock, for instance, in which absorption does not take place from the stomach, or is greatly impaired.

NEW SOURCES OF DANGER IN THE USE OF OPIUM.*

T. D. CROTHERS, M.D.
SUPERINTENDENT WALNUT LODGE HOSPITAL.
HARTFORD, CONN.

In a paper read last year at Columbus, on the use of opium in infancy and the effects in adult life, some serious injuries following its use were pointed out. It was shown that both the brain and the nervous system suffered from retarded and perverted growths and other derangements which continued in after life that were clearly due to the early use of opium. In this paper I wish to carry the study farther and to point out some new states of degeneration which have not been noticed before. In my former paper it was stated that opium in any of its forms, given for any length of time, not only weakens the nervous system, but predisposes it to functional and organic diseases marked by a craving for drugs and narcotics. I shall attempt to show that opium used under certain conditions produces a diathesis and a tendency which may be dormant for a long time and then break out into opium addiction from the application of some special exciting cause.

It is a common observation that the effects of opium differ widely in different persons. It is usually given for neuralgias, spasmodic disturbances, and common fluxes. Its effects change not only with the size of the dose, but with some physiologic receptive or repelling power in the organism. In one instance its narcotic action is prompt and soothing; in another it is first a stimulant, then a depressant, and later an irritant; or it may produce nausea at first and a depressant action after. Its narcotic effects are at times transient, uncertain or cumulative. In some instances, several doses are given before its effects are noticed, then a cumulative action of all seems to concentrate in profound narcotism. In certain cases the effects are not marked for many hours; in others they continue for a long time, wearing away by slow degrees. These are supposed to be due to idiosyncrasies, and indicate degrees of susceptibility to or immunity from the poisonous states caused by the drug. They also show some repellant or receptive power to its effects within the body. In a clinical study of opium inebriates examples are seen in which opium or some of its preparations have been given for medicinal effect years before the addiction began. Used for a specific purpose under the care of a physician, it was stopped when the necessity ceased, without any indication that it would be used again. Years afterward it was suddenly taken up without apparent cause, and continued as an addiction. Some exciting causes appear to have aroused a craving for narcotics which in some way dated back to their early use. A predisposition or diathesis was created which remained latent in the system and broke out only on the application of some peculiar exciting causes. The following illustrative examples bring out the clinical history of such cases.

---

*Presented to the Section on Materia Medica, Pharmacy and Therapeutics, at the Fifty-first Annual Meeting of the American Medical Association, held at Atlantic City, N. J., June 5-8, 1900.

Example 1.—A merchant in good health up to the time of an attack of influenza was given a small quantity of opium daily for two weeks. He fully recovered from the influenza, but began to use opium secretly. Two years after, he threw off all restraint and used it boldly in large quantities. Coming under my care, I found that opium had been used twenty years before for a chronic diarrhea following a term of service in the Civil War. He was given opium pills daily for nearly two months; then recovered. Four years later some obscure neuralgias of the bowels caused him to use opium again. He recovered from both of these attacks, having no craving for the opium or difficulty in stopping its use. In these instances the action of opium was pleasing and the narcotism profound and without any unpleasant impression. The opium was stopped on the recovery of the patient. A few months later he began to use it again, and came under treatment, and in a few months was discharged restored. Relapse followed the next year, and he is now a chronic case in which final recovery is doubtful. In this case there was no history of heredity or of neurotic conditions which would predispose the use of the drug. The use of opium for the chronic diarrhea impressed the organism, creating a diathesis which called for its use from the slightest exciting causes.

Example 2.—A young married woman found in opium a complete relief from the nausea and vomiting which accompanied pregnancy. The opium was continued, and after the death of the child, increased to large quantities daily. She was treated in various asylums and sanitaria, and after each restoration invariably relapsed. Finally she went to an insane asylum, and died demented. In the history of this woman it was stated that at 13 years of age she was treated for neuralgia and exhaustion. This was supposed to have come from intensely active school life and ambition to keep at the head of her class. She was insomniac and intensely neuralgic. The menstrual period began about this time, and morphia was given with pleasing effects for nearly two months, after which it was abandoned. She fully recovered, and did not know the character of the drug she had taken. She continued well for seven years, not using any form of opium or narcotic. Finally the vomiting of pregnancy occurred, which was treated with opium. The early use of opium was clearly the predisposing cause of its later use. There was no mental influence in this, because of ignorance of the name and nature of the drug given at first. The system seemed to respond with absorbing fascination for opium, and the relief which it brought was so pleasing that it could not be abandoned. It is doubtful whether this effect would have followed had not opium been used long before, the system being thus prepared for it.

Example 3.—A lawyer, temperate and healthy, 54 years of age, suffered from a fractured ankle, in which both bones and nerves were injured. The pain was relieved promptly by morphia, which was continued for several months, and withdrawn with the healing of the wound. No addiction or injury followed. Six years afterward, from the depression and grief caused by death in his family, he secretly purchased a needle and again began to use morphia. This was continued for two years; then he came under my care for treatment. He recovered and relapsed within a few months, and is now a morphinomaniac. There was no history of heredity, and no previous addiction to the drug before the time of injury. The use of morphia at the time of injury produced a permanent impression upon the organism, which broke out later in the form of secret addiction.

In these three cases, opium seems to have had a peculiarly pleasing narcotic effect, particularly on the pain centers, with no depression or irritation afterward. For purposes of comparison, the following are noted as cases exhibiting different phases of sensitiveness from the use of opium.

Example 4.—A rugged, healthy farmer, after exposure to the weather, was attacked with severe pain and high fever. Morphia was used. Its effects were those of an extreme excitant for an hour or so; then an ill-defined stupor, followed by nausea and increased fever. Opium in various forms was given with the same results. The excited stage never fully passed away, and the depressed stage was short and uncertain. He recovered, and a few years afterward, when ill, seemed to have an intense dread lest opium should be given as a medicine.

Example 5.—A mechanic, suffering from an attack of acute rheumatism, was given opium. The narcotism was rapid and profound, but was followed by a period of intense irritation of the stomach, which lasted several days. The rheumatism subsided, but the impression of the effects of opium produced a sickening, repellant sensation on his mind ever after.

Many neurotic affections and inflammatory states are relieved by opium, the first effect of which is that of a narcotic, then a stimulant and irritant. It is this stimulant action which is so fascinating to the alcoholic. When it is not followed by irritation of the stomach and nausea, the use of spirits is abandoned for that of opium. The pleasing narcotism makes so profound an impression as to overcome all the irritation and bad feelings; hence alcoholics use opium to escape the gastric and other irritations following the use of spirits. Apomorphia, now given to check the desire for spirits, is noted for its nauseating and irritant effect, followed by depression and narcotism. The relaxation and depression from apomorphia is intensified by the taking of spirits, and is followed by great discomfort and repugnance for the taste and effects of spirits. [illegible] marked poison effects are [illegible] tr[illegible] alth[illegible] impression may be so p[illegible] place in the system, [illegible] opi[illegible] spirit addiction or som[illegible] cotic stage is often permanent in its impression on the organism, and the irritant effects are transient and soon forgotten. In a case under my care an excessive user of spirits turned to morphia for relief from the delirium and other conditions which followed the use of alcohol. After the narcotic stage passed, intense irritation of the stomach, with mental depression, appeared. These caused a recourse to spirits again. He finally returned to morphia, under the impression that a withdrawal would cause his death.

In many instances, when opium is taken in a prescription or alone for some chronic condition, poison-states follow, not recognized as due to this cause. Some of these symptoms are noted in headaches, sensory troubles, local palsies, depression of spirits and other emotional changes. In one case the withdrawal of opium in a prescription for bronchitis was followed by the disappearance of marked muscular prostration. In another instance sensory troubles and digestive disturbances passed away when the opium was removed. The use of any form of opium should be watched with care and abandoned at the earliest moment when the effects sought for are obtained. The poison-effects in extreme nausea, in some cases, leave a permanent impression and a peculiar sensitiveness to this and other drugs, which may continue for years. In some young persons who have suffered in this way, intense mental and organic aversion is apparent whenever it is used again. The size of the dose may not make much difference. This sensitiveness and extreme susceptibility is often manifest in both narcotism and irritations from the use of the drug. This may be overcome by persistent use, and some instances of addiction have had an early preliminary period of repugnance for it. There is always a degree of exhaustion following the use of opium, especially when it acts as a stimulant and irritant to the nerve-centers. In some instances the transient excitement following its use is noted by great mental activity and freedom of thought. This is supposed to be mental stimulation; in reality it is irritation and delirium, and is always a dangerous symptom. It is this which is sought by the alcoholic, to relieve the depressing effects of spirits. In this the brain is often permanently disturbed and extreme states of exaltation and depression break up the stability of the nerve-centers, as well as the power of control.

When opium has been used with pleasing effects, then long afterward taken up again, there is a psychic effect not seen in other cases. A tendency to secrecy and concealment is marked, with denial of all use of the drug. The quantity used will be misstated, and the efforts to secure it and to provide for an emergency will be strange and unusual. In such cases the danger of poisoning and fatal results from an overdose is very small. The danger-line seems to be overcome and the poison-limit rarely reached. When opium is followed by irritation and nausea with sudden narcotism and pronounced poison-effects there is danger of fatal results. Often large doses are followed by progressive stupor, which continues to final collapse. Here there seems to be no resisting power, the action of opium pervades the entire system like the exhaustion which precedes sleep. The use of opium in which no organic changes or special perversions of the functional activities are apparent is a strong indication of a diathesis and physiologic predisposition difficult to overcome.

Another source of danger has attracted but little attention. It is the effect of opium on fetal life and growth. Many instances are reported of children born of mothers who used opium during pregnancy, which at birth showed defective organisms, low vitality and marks of anemia. The nervous system was imperfectly developed and hypersensitive, the child crying continuously, and only securing relief from the use of opium. I have recorded several instances in which the excessive irritability of infants was only overcome by opium. Most of these died early from exhaustion and acute diseases. Many observations sustain the assertion that alcohol or opium used by the mother both perverts and retards organic growth of the child. Some very interesting facts have been noted by Nicloux, in *La Semaine Médicale.* As a rule, all children born of opium mothers die early, but are not observed very thoroughly.

Probably there is no article in the materia medica more commonly used or more valuable than opium and its preparations. Yet its effect on the nerve-centers, on nutrition and organic growth is very largely an unknown field of study. The facts I wish to make prominent are: 1. The use of opium continuously for any possible purpose is dangerous in that it may impress the organism in some unknown way and leave a diathesis and susceptibility to resort to it again in after life. 2. The condition called opium addiction, in which the drug is used for its narcotic and pleasing effects, is one of organic disease whose origin is preventable by a study of the conditions and peculiarities of the person in early life. 3. Where opium is used with but little, if any, irritant effects, there exists a predisposition to its continuous use and the development of an addiction. 4. When its poisonous effects are marked in the irritations and exaltations which follow its use there is great danger of organic changes and diseases with fatal results. 5. The psychic element in these cases furnishes very suggestive hints of the derangements which follow the mental perversions and disturbances of reason and judgment, and gives some idea of the profound organic changes which take place.

DISCUSSION.

DR. J. M. ALLEN, Liberty, Mo.—Having been impressed with the importance of the subject presented by Dr. Crothers, early in my professional career, I have exercised great care in prescribing opiates, fearing their baneful influences, and am happy to say I have never had an opiate habitué as the result of my treatment.

In many instances I have noted the tendency of patients to a fondness for this remedy, and have had some trouble in having them discontinue its use. In after-treatment of acute disease with them, I have been very careful to disguise the opiate, and never let them know they are taking it. In all cases where there is a tendency to become addicted to opium, either in children or adults, I have been able to trace a hereditary tendency in the parent to indulgence in alcoholic stimulants. It is a well-established fact that alcoholic heredity may skip one generation and appear in the next. I have had three examples of this. The relations of alcoholic heredity producing an abnormal condition of the nerve-centers in which some of the offspring have a fondness for narcotics, I have observed frequently.

I can safely say that all of the narcotic habitués that have come under my observation had for their ancestors fathers and mothers who were addicted to the use of alcoholic stimulants. In support of this, I give a history of one family: A prominent citizen, whose family history was the free use of alcoholic stimulants; he was what would be called a moderate drinker, but drank daily; a very robust man mentally and physically; he had an acute painful illness; the physician was compelled to give opiates. I saw him in consultation at the end of twenty days, and was astonished at the large amount of opium he had been taking. The physician in attendance told me that he recognized that opiates were not now needed, but that the patient demanded and would have it.

We had a patient, an opium habitué produced in thirty days, who had to be treated for same. He recovered and had his physician pledge him never to give him another grain. This gentleman's family of six children had an intense fondness for the effects of opiates. Several of them told me so great was their fear, knowing their fondness for opium, that they never wished me, or any other physician, to prescribe it, no matter how much pain they might be suffering.

In conclusion, I desire to enter my protest against the unnecessary use of the hypodermic syringe in giving opiates, because of their being more seductive in that form than when given by the mouth.

Dr. Warren B. Hill, Milwaukee—Too much importance can not be placed on the views entertained by the reader of the paper. There is a theory in regard to the action of narcotics, which has not been demonstrated, but which is so reasonable that one can believe it. It is that by the action on the human body a tolerance is brought about, just as immunity from infection, through the formation of certain toxins, owing to the stimulation of the cells. In this way patients become gradually able to take very large doses of the drug, owing to the protection of the system by the development of their toxins, the presence of which prevents the usual effects from being produced. Therefore, when we constantly give increasing doses of morphin, its antitoxin is formed and a tolerance is established but if the morphin be suddenly stopped, the antitoxin in the system causes irritation and disturbances of the nervous system and demands a continuance of the drug for its relief. Another point; if we could only find out just how much opium the patient actually needs to overcome the condition for which we prescribe it, we could in many cases avoid the dangers of overdoses, and prevent the formation of a habit, but we can not do this and consequently frequently give an overdose, and this tends to create a demand for it in the system. This is more likely to occur with children; therefore, as the lecturer has shown, there is greater danger from opium in children than in adults. There is another and very important consideration—it is that if a man acquires an immunity against any drug he runs the risk of transferring the immunity to his descendants. Therefore, when we give opium, especially to children, there is a danger of forming this condition, which is capable of being transmitted to descendants of the patient.

Dr. T. B. Greenley, Meadow Lawn, Ky.—I wish to call attention to the fact that family medicines often given to children owe their power chiefly to opium. Some persons are also fond of giving paregoric to young children. It quiets them and relieves their pain and the nurse will increase the dose from time to time. No doubt the foundation is often laid in this way for the formation of the opium habit in afterlife.

Dr. Jos. T. Smith, Baltimore—We all acknowledge the great relief that is afforded by opium in many of the evils and annoyances of life. It would appear that one of the reasons why there are not more cases of opium addiction than there are why we do not all become opium habitués, is the fact of the existence of an internal resistance, which most of us possess. This prevents us from yielding to the seductive attractions of the drug. There are some individuals who do not possess this normal internal resistance and when they experience the relief from pain and the pleasant effects from the use of narcotics, they will on the slightest provocation rush to the use of some means of relief. Many resort to alcohol, others to cocain, and others again to opium, finding excuses for repeatedly returning to the drug, whatever it may be; following along the line of least resistance. This is one of the causes of the condition referred to by Dr. Crothers. The patient who first takes a dose of opium, for instance, for chronic diarrhea, as in one of the cases mentioned, is gratefully surprised with its pleasant effects and resorts to it again and again until he becomes addicted to its use. The most of us resist evils as long as possible, but such cases yield without resistance and demand the influence of a drug. They live on the sense plane and can not rise above it, as the majority of persons in the world have learned to do.

W. W. Tompkins, Charleston, W. Va.—I wish to mention a case of a man 53 years of age, suffering from stone in the kidney. He had been under observation for several years. He consulted several specialists, who advised removal of the kidney. He would not consent; a few months later he passed the stone and had complete relief. During these months, however, it had been necessary, from time to time, to give him morphin amounting to six grains daily. He afterward showed no tendency to opium addiction, and never took another dose after passing the stone. He had used whisky for thirty-five years and used it simultaneously with the morphia during his illness. After passage of the stone his desire for liquor left and he had no craving for morphia, the mere mention of it producing nausea. I think the above case interesting in two particulars: 1, the fact that after using morphin for so long the habit was not formed; 2, the discontinuance of alcoholics after such a long period and no substitute taking their place.

Dr. A. B. Lyons—In connection with this subject, it should be remembered that there are certain persons, whose temperament leads them to fall in love with drugs at first sight. There are some individuals who, when they make the first acquaintance with the effects of a narcotic, become slaves to it. Whether acquired or hereditary, the temperament is the immediate cause, as in the case of chloroform addiction, in which a single delightful experience may create a desire for further indulgence and require a great effort to prevent the formation of the habit.

Dr. J. N. Upshur—In listening to the paper it strikes me that the point from which the correction of this evil should start is in the teaching of the colleges. The dangers of the reckless use of opium in prescribing should be impressed upon students in their college days. The teachers of clinical medicine are too apt to recommend a resort to opium or morphin for the relief of pain and suffering. The students leave college with the idea that opium is the sheet anchor against all cases of suffering and they consequently are led to resort to it too frequently. I fear that there are some physicians who are willing to put their patient to sleep merely that they may sleep themselves. This is a most important subject and it rests with teachers of medicine to impress upon the minds of their students the great responsibility involved in prescribing these drugs, and the great damage that may follow their use.

Dr. Frank Woodbury—I would like to know whether we should not draw a distinction at the present day between opium addiction and the morphin habit, both as to the liability to form the habit and the consequences. The hypodermic syringe makes it easy to form the morphin habit, and individuals who have established this habit can rarely be made to change the method of administration by the mouth. Moreover, we know that morphin does not fully represent the drug, opium, which contains other constituents which are exciting and tetanizing, and therefore antagonistic to morphin. The results might therefore be expected to be different. The old-fashioned form of opium addiction by the use of the tincture, I believe to be not only safer and more physiologic, but also more easily treated in case the patient desires to discontinue its use, and I would like to have the benefit of Dr. Crothers' experience on this point.

Dr. T. D. Crothers, closing the discussion.—This paper has been brought before the section to call renewed attention to the evils from routine use of narcotics in practice. Notwithstanding all that has been written, many physicians continue to use opium as freely as if there was no possible danger or possible after-effects from its use. This is a mistake which is becoming more and more apparent from any careful examination of the history of obscure cases. Morphia is probably the most prompt and efficacious of any form of opium in common use. The tincture of opium is the common form and differs from morphia in being less prompt, but its effects last longer. No matter in what form the opium may be given there may be present a special predisposition to continue its use, and in that way a psychosis established which will permanently impair the brain and nervous system. One central fact should never be forgotten, that the use of opium in the parents or given in early childhood is likely to [illegible] a [illegible]osition which will develop into an addiction from the slightest exciting cause in after years.

SECONDARY GLAUCOMA.

A CLINICAL AND PATHOLOGIC REPORT OF THREE CASES, REPRESENTING DIFFERENT TYPES OF THE DISEASE.*

WM. CAMPBELL POSEY, M.D.
AND
EDWARD A. SHUMWAY, M.D.
PHILADELPHIA.

Secondary glaucoma may be defined as being that variety of glaucoma which occurs as a result of some preexisting disease of the eye which has caused an increase in the intraocular tension by obstructing the angle of the anterior chamber. It is not the purpose of the writers to enumerate the conditions which may effect this closure, but merely to give a detailed report of three cases which occurred in their practice, in all of which such an occlusion was found, and in addition, to call especial attention to conditions which existed in two of the eyes.

Case 1.—J. E. G., male, aged 39 years, first consulted Dr. Posey about his eyes three years ago. His primary ocular affection dated back four years, and was said by the patient to be characterized by pain, redness and dimness of vision in both eyes, though he thought that the inflammation was more severe in the right eye. He was treated for this attack over a period of some months by the late Dr. Keyser, and recovered with good vision in each eye. Shortly after the inflammation in the eyes had subsided, however, transient attacks of redness in his right eye occurred, which were associated with pain that was most severe in the temple, but sometimes radiated into the nose; vision also began to deteriorate. The left eye occasioned him no trouble. Instead of consulting an ophthalmologist, he applied domestic remedies of different kinds to the affected eye, and continued them for several years, as he found that he succeeded in reducing the acute symptoms by these measures fairly well.

As he noticed several months prior to consultation that the attacks of inflammation recurred more often, and that the remedies which he employed were no longer so successful in causing their subsidence, and as his vision had become much reduced, and the pain was at times almost unbearable, he decided to seek proper surgical aid.

At the time of the first examination it was ascertained that the right globe was in an advanced stage of secondary glaucoma; there was intense ciliary injection, with engorgement of the peri-corneal veins; the cornea was hazy and presented a needle-stuck appearance; the anterior chamber was almost obliterated; the iris was discolored and thickened; the pupil was 3 mm. in size and was immobile to light. Tension was +2. No view could be had of the fundus by the direct method of ophthalmoscopic examination on account of the corneal haze, but with the indirect method a deep glaucomatous excavation with dilatation of the retinal veins could be clearly seen. Vision equaled 3/50. The left eye was quiet, though a faint annular stippling of pigment upon the anterior capsule of the lens evidenced a previous iritis in that eye also. The fundus was plainly seen, and showed no gross pathologic change other than a diffuse perivasculitis of the retinal vessels, which was most pronounced in the large arterial streams. The field of vision was reduced to a small triangle, the apex of which corresponded to the fixation point, and the base to a segment in the temporal field about twenty degrees broad. Central and peripheral vision in the left eye was normal.

As the patient admitted having had a primary sore some eighteen months previously, he was at once placed on a dram of mercurial inunction twice daily. Two drops of salicylate of eserin—gr. 1/8 to the ounce—and five drops of muriate of cocain—gr. 4 to the ounce—were ordered to be instilled into the eye five or six times daily, and his bowels were freely opened by salts in the mornings. After two weeks of this active treatment, the eye had improved to such an extent that the vision now equaled 5/15, the cornea was practically clear and all the details of the fundus could be seen with the direct method, the head of the nerve being found to be excavated both above and below and to the nasal side though but slightly to the temporal side. Two weeks later, one month after the installation of the inunctions, vision was brought to normal by +1.5 Sph.+3 cyl. ax. 20°; the field of vision, however, remained as before.

About one week later the patient returned acknowledging that he had relaxed some of the details of the treatment, and complained of intense pain and poor vision in the affected eye. The ciliary injection, which had entirely subsided, had recurred with great intensity, and the cornea was now exceedingly hazy. The iris was congested, and, at a point to the nasal side corresponding to the minor circle of the iris, there was a small yellow spot with marked engorgement of the vessels in this position. A small hypopion had also formed at the bottom of the anterior chamber. The patient was at once admitted to the Howard Hospital, his temple leeched, and ice compresses applied to the eye almost constantly, and cocain—gr. 4 to the ounce—instilled every two hours, the eserin being withdrawn. The bowels were freely opened by rochelle salts and the mercury continued. After a few days of this treatment the eye again whitened, and at the end of two weeks he was discharged from the hospital, corrected vision equaling 5/6.

For several months after this the eye did uniformly well, although the patient was compelled to be extremely cautious regarding his manner of living, and most assiduous in the care which he gave to his eyes. After an interval of several weeks' absence from the office, and following some indiscretions in his manner of living, another glaucomatous attack supervened; light perception was abolished, and the eye was so painful that enucleation was advised and willingly consented to. The patient was re-admitted to the Howard Hospital, and the globe removed under ether narcosis. The socket healed rapidly after the operation and an artificial eye was inserted several weeks later. The patient was seen after the lapse of a year, and found to be using his remaining eye without any discomfort. Vision equaled 5/5 with the proper lenses and the eye was entirely free from inflammation.

The eyeball was placed in Mueller's solution at the time of operation, and was subsequently frozen in a mixture of ice and salt, and cut into halves by a horizontal section passing through the optic nerve and the center of the cornea. One-half was mounted in glycerin jelly for macroscopic demonstration while the other was carefully dehydrated in alcohol and embedded in celloidin. The sections obtained for the celloidin-mounts varied in thickness from 1.15 to 1.25 mm., and were stained in hematoxylin-eosin, Van Gieson, and by Weigert's nerve-sheath method. The other two eyeballs were treated in the same manner.

---

*Read before the Ophthalmological Section of the College of Physicians of Philadelphia, April 17, 1900.

Pathologic Findings.—Macroscopically, the globe measured 22 mm. in the antero-posterior diameter, and 23.5 mm. in the horizontal diameter. Retina was in place; anterior chamber shallow at the periphery; nerve atrophic and nerve-head pathologically excavated.

Microscopically, the cornea is normal, except for distension of the vessels at the limbus. The base of the iris is adherent for a short distance anterior to the canal of Schlemm, and the distance between the iris and cornea anteriorly is very much reduced. The iris shows changes due to low-grade chronic inflammation, as indicated by an increase of the cellular elements, moderate condensation of tissue, decided thickening of the vessel-walls, and some heaping of pigment, especially in the region of the sphincter. There is one small posterior synechia above, inside the pupilary area. The lens shows nothing abnormal. The nerve is reduced in volume and the connective-tissue septa are hypertrophied.

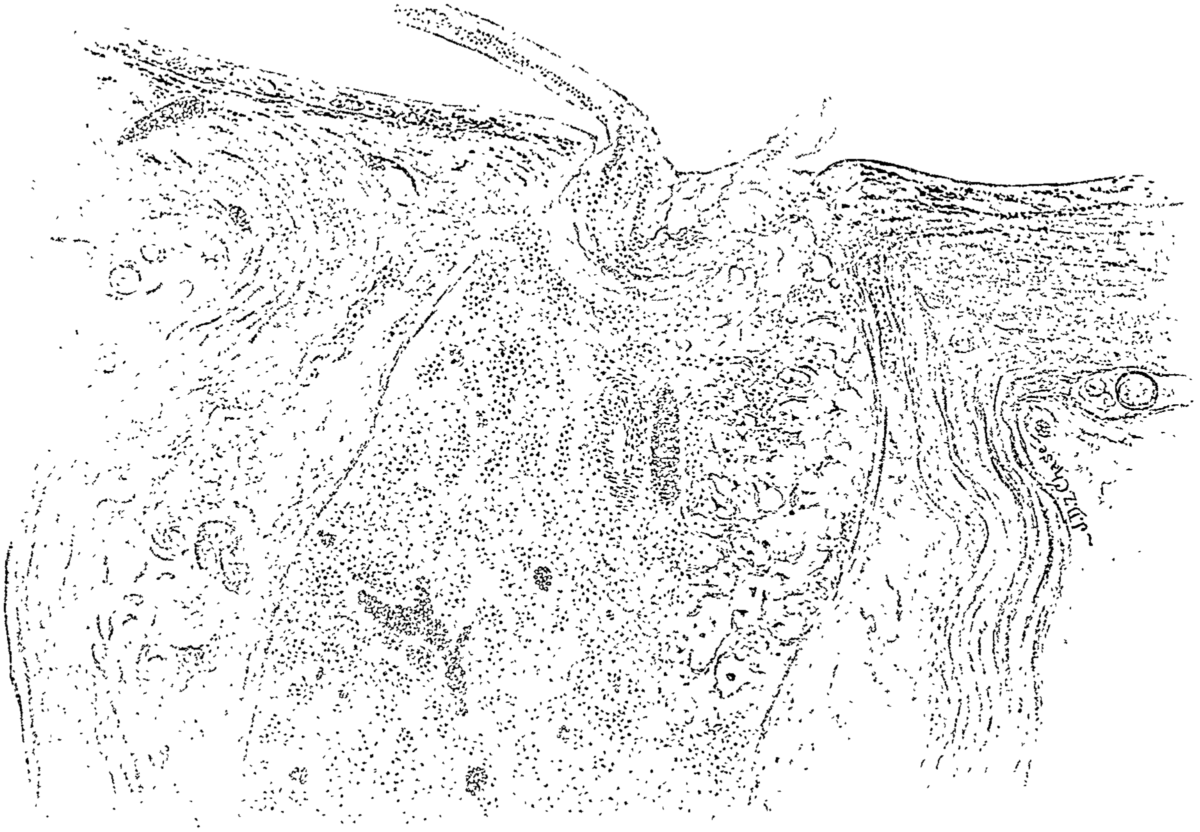

Plate 1.—Sketch of optic nerve entrance, showing area of rarefaction.

The excavation in the nerve-head is .75 mm. deep, with very steep edges, especially on the nasal side; it involves the entire papilla, and is partially filled with a mass of loose-meshed connective tissue—neuroglia fibers—but the nerve fibers are pressed to one side. The fibers of the lamina cribrosa bend backward in a sharp curve. On the temporal side of the nerve, beginning at the level of the excavation, and extending backward a distance of 2 mm. from the bottom of the excavation, there is a cyst-like space, reaching from the external sheath of the nerve, almost to the central vessels. (Plate I.) At this position there is a marked atrophy of the connective-tissue bundles; the fibers being reduced in size and widely separated, leaving gaps in the tissue. Except at the margin of this cavity, where a few of the nerve-fibers retain the Weigert stain, the nerve bundles have not only become atrophic but have absolutely disappeared, but little trace remaining of the neuroglia cells and investing pial sheath. Elsewhere there is complete atrophy of the entire nerve except for a few peripheral fibers on both nasal and temporal sides. There is, however, no disappearance of the investing sheaths as in the cavity described above. The intervaginal space is widely distended. The retina was artificially detached in hardening, but the layer of rods and cones and the nuclear layers all seem to be well preserved, while the ganglion cells appear to be much reduced in number and their nuclei stain poorly, but as the specimen was hardened in Mueller's fluid the Nissl stain was refused and their exact condition can not be determined. The pigment layer is normal, there being no proliferation of the cells, or pigmentation of the retina. The choroidal vessels are distended but otherwise this tunic and the sclera are entirely normal.

Diagnosis.—Chronic iritis, blocking of anterior chamber; secondary glaucoma, with excavation of nerve-head, and nearly complete atrophy of the nerve. Complete disappearance of the nerve-fibers and investing tissue in one portion of the nerve. Beginning atrophy of the retina.

Case 2.—B. McK., female, aged 30 years, presented herself at the ophthalmologic clinic of the Howard Hospital eighteen months ago with a history of having sustained a fall on the ice five years previously, as a result of which she had received a severe blow in the right temple. The eyelids of this side of the head were swollen to such a degree that leeching was necessitated. After the swelling in the temporal region had subsided, she noticed that the right eye, which had always been nearsighted, was now almost blind. She made no effort however, to have the vision in the eye improved, nor to obtain relief from transient attacks of pain and redness, which manifested themselves in the eye at frequent intervals for several years after the accident. Finally, however, the pain became so acute that she decided to seek professional advice, although she now despaired of anything being done to restore the sight, as the eye had been quite blind for five months.

At the first examination, the tarsal and ciliary injection in the right eye were seen to be intense; the anterior chamber was shallowed at the periphery, though the iris was bombé and its pupilary edge in-drawn, especially below. The lens was densely cataractous and emitted a yellowish reflex. Tension could not be determined, on account of the intense degree of ciliary tenderness. The left eye was quiet, and presented no changes other than are usual in a myopic eye of 16 D. Vision in the right eye was reduced to perception of light excentrically to the temporal side; vision in the left eye equaled 5/20.

Enucleation was advised and successfully accomplished by Dr. Shumway a few days later under ether narcosis.

Pathologic Findings.—Macroscopically, the globe measures 24.5 mm. in the antero-posterior diameter, and 24 mm. in the horizontal diameter. On the temporal side there is a shallow posterior staphyloma, the sclera being moderately thinned in this position. The retina is totally detached, and the subretinal space filled with a homogeneous exudate. The anterior chamber is shallow at the periphery, but quite deep at the center, and the lens and iris are imbedded in a mass of exudate.

Microscopically, the cornea shows a moderate infiltration with round cells at the periphery and the vessels at the limbus are distended with blood. Descemet's membrane is normal at the center, but on each side has been ruptured, and remains adherent to the anterior surface of the iris, to which it is attached by a layer of partially organized exudate, showing that during life the iris was pressed against the cornea. The filtration angle is blocked and on the nasal side the canal of Schlemm is surrounded by infiltrated cells containing pigment, evidently derived from the iris and ciliary body. The iris shows evidence of chronic inflammation, being covered anteriorly with an exudate containing but few cells. The stroma is much condensed, having been converted into dense connective tissue; the vessel-walls are thickened and their lumen is nearly obliterated in places, but everywhere filled with blood. The pigment is deposited in irregular clumps and in certain areas is much proliferated. It is attached to the lens capsule in several places by an organized exudate, and the lens capsule is covered with a similar though thinner membrane in the pupilary area. All communication between anterior and posterior chambers is thus abolished. On the nasal side, the attachment between the iris and lens is nearly complete, and where this has occurred the lens shows several small capsular cataractous formations between the capsule and its lining epithelium. The lens is imbedded in an exudate which contains but few cells on the temporal side, but which is organized on the nasal side where it is connected with the dense adhesions between the iris and the lens capsule. Here the ciliary processes are drawn inward, and the pigment epithelium on their inner surface is very markedly proliferated. The ciliary processes are becoming atrophic, and there is beginning detachment of the entire ciliary body, the fibers being pulled apart and the interstices filled with fluid. The lens, in addition to the capsular cataracts noted above, shows a splitting up of the fibers, and their conversion into irregularly round masses, especially at the posterior pole, and at the equator. No laceration of the capsule can be seen. The choroid is thin and atrophic, the fibers composing the stroma being widely separated, probably by the shrinking of the subretinal exudate during the artificial hardening of the globe. The retina is totally detached, and extends as a folded and twisted membrane from the nerve entrance almost to the lens, and then turns abruptly to its attachment at the ora serrata. It is partially disorganized; the rods and cones have entirely disappeared; the molecular layers are fairly regular, but the nerve-fiber layer is very much thickened, being converted into dense connective tissue, and the ganglion cells have disappeared. The nerve shows an increase in the cellular elements. On superficial examination, the fibers appear to retain the Weigert stain remarkably well, but under high power the myelin sheaths are seen to be broken down in places into fine drops. The degeneration is probably acute and does not involve the majority of the fibers. The nerve entrance is oblique, and there is a moderate distension of the supra-vaginal space, but no marked pulling of the nerve toward the temporal side. The sclera is normal, and at the position of the shallow staphyloma on the temporal side, shows a thickness of .55 mm. in contradistinction to a thickness of .95 mm. at the corresponding point on the nasal side of the nerve.

Diagnosis.—Detachment and secondary fibroid degeneration of retina; plastic iritis with posterior and anterior synechiæ; occlusion of pupil; anterior capsular and posterior cortical cataracts; blocking of angle of anterior chamber, and secondary glaucoma in myopic eye.

Case 3.—L. W., aged 61 years, said that her left eye had become blind ten years previously from an ulcer for which she had been treated at another hospital. No history of traumatism could be elicited, and as she was in apparent good health, the cause of the ulceration had been attributed to "catching cold." Although the eye had remained quiet for a time after the primary inflammaton had been combated, she had suffered repeatedly from attacks of pain and redness in the eye, from which she obtained only partial relief by the persistent use of drops which she obtained from various clinics.

At the time of the first consultation at the Howard Hospital, both tarsal and ciliary congestion of extreme degree were noted as occurring in the left eye. The cornea was hazy throughout its entire structure, but at its center there was an irregular denser area of scar tissue. There were two similar narrow bands to the nasal side. The anterior chamber appeared to be very deep, the plane of the iris being drawn backward. A yellow reflex was obtained from the pupil, but no red glare could be detected. Tension was elevated, but it was impossible to ascertain to what degree on account of the extreme sensitiveness of the eye. The right eye was slightly hypermetropic, but presented no other changes, its vision equaling 5/9. Sight in the left eye was totally obliterated.

Enucleation was advised and successfully performed by Dr. Shumway under ether narcosis.

Pathologic Findings.—Macroscopically, the eye measures in the antero-posterior diameter 20 mm. and 20.5 mm. in the horizontal diameter. The anterior chamber is very deep, and the cornea is conical, 8 mm. in diameter, the periphery being drawn inward and backward. On the nasal side, just posterior to the ora serrata, the sclera is also drawn inward. No portion of the nerve appears. The retina is detached and degenerate, the vitreous cavity being filled with a mass of exudate and blood.

Microscopically, the corneal epithelium is thickened and everywhere separated from Bowman's membrane by a round-cell infiltration, and by minute blood-vessels. This round-cell infiltration is densest at the limbus, where the epithelium is widely separated from the cornea. In the substantia propria there is a moderate extension of round cells between the deeper layers. At the central part of the cornea Bowman's membrane is interrupted, and directly beneath this the laminæ are replaced by dense scar tissue. The cornea is thinned in this area, and Descemet's membrane absent, a sharp notch appearing in the posterior surface of the cornea, which is partly filled with degenerate cells partially pigmented and with pigment clumps. This apparently indicates the point of perforation of the cornea, with attachment of the iris. Descemet's membrane is intact elsewhere.

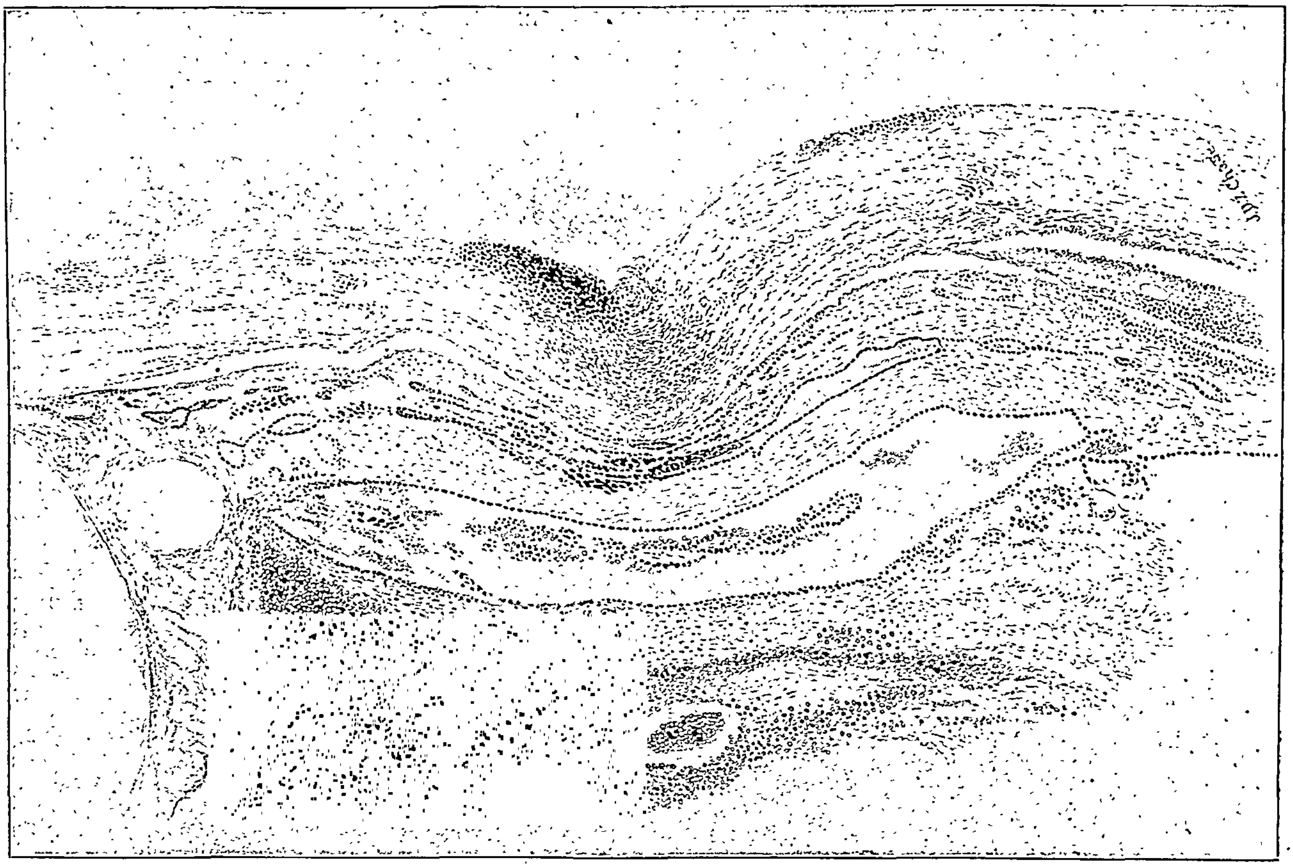

Plate 2.—Exudate on choroid, showing cavities lined with pigment epithelium.

The iris is firmly attached to the posterior surface of the cornea, at the periphery, and is completely atrophic, being reduced to a thin connective-tissue layer. There is a beginning intercalary staphyloma. The anterior chamber is partially filled with blood and a homogeneous exudate. The lens is surrounded by a mass of exudate which is firmly organized anteriorly, forming a dense membrane extending between the margins of the iris, and completely occluding the pupil. This exudate is less firmly organized posteriorly, and fills up the remnants of the vitreous cavity between the ciliary processes, lens, and detached retina as a layer of loose connective tissue, with numerous round cells, and minute capillaries, which spring from the retina at the ora serrata. The ciliary muscle is atrophic, infiltrated, and the processes drawn inward and forward by the exudate. Its pigment layer is markedly proliferated. The retina anterior to the ora serrata is cystic, the supporting fibers being drawn inward by the shrinking exudate, and the cavities thus formed are filled with a homogeneous fluid. Just posterior to the ora serrata, the retina is detached and bends sharply forward and merges into the mass of exudation posterior to the lens, becoming completely degenerated. All of its elements have disappeared, and its situation can be recognized best macroscopically by an indistinct bluish line, extending backward from the lens, which under higher power is seen to be composed of a mass of granular debris, red blood-cells, and a few partially staining nuclei imbedded in a fine-meshed reticulum. The pigment epithelium of the retina in places is fairly regular, but in others it has disappeared. The choroid is thickened to several times its normal size, and shows numerous irregularly circular masses of fresh round-celled infiltration. The meshes of the choroidal stroma are widely separated. The surface of the choroid is covered with a firmly organized layer of exudate which on the temporal side is over one mm. in thickness, into which the proliferated pigment epithelium extends. This exudate shows wide spaces anteriorly lined with flat pigmented cells and partially composed of red corpuscles and leucocytes. The exudate is chiefly composed of spindle cells and fine fibrillary tissue, and contains a large amount of light-colored pigment in clumps, probably of hematic origin, numerous round cells and freshly extravasated red blood-corpuscles. The space between it and the detached retina is filled with a mixture of fresh blood and of a homogeneous exudate, staining pink with the eosin. Near the nerve entrance on the temporal side there is an area of calcification in the exudate.

The sclera and episcleral tissue in the ciliary region are infiltrated with round cells on the nasal sid [illegible] ust posterior to the ora, the sclera is [illegible] and at this point shows an [illegible] filtration. At a corresponding point in the choroid, there are a series of circular areas of complete cell-necrosis, containing a fine granular debris measuring about one mm. in diameter. There is, however no proliferation process surrounding them, and they probably represent previously deposited masses of round cells. The lens is cataractous and shows several areas of calcification. Unfortunately, the nerve was not included in the sections. It would certainly have shown complete atrophy.

Diagnosis.—Irido-choroiditis following perforation of the cornea. Secondary cataract. Occlusion of filtration angle of anterior chamber, secondary hemorrhagic glaucoma. Detachment and complete degeneration of the retina. Beginning atrophy of the globe.

It is of interest to note, in connection with these cases, that all exhibited a greater or less degree of blocking of the angle of the anterior chamber, and that it was, as a consequence of the impediment which was offered to the escape of the intraocular fluid through the lymph-channels in this position, that the glaucomatous symptoms supervened. In Cases 2 and 3 there was in addition, occlusion of the pupil and interference with the communication between the anterior and posterior chambers. Coinciding with the relapses which were manifested clinically all three eyes showed changes, the result of different stages of inflammatory action.

Case 1 is of peculiar interest from the fact that despite the very severe clinical manifestations in the anterior segment of the eye, the microscopic changes in the iris ciliary body are remarkably slight. The writers wish to call especial attention, however, to the peculiar cavity in the optic nerve of this eye, as a careful search through the ophthalmologic literature has failed to discover any similar condition. No less an authority on nervous tissue than Dr. William G. Spiller, to whom the sections were shown, states also that so far as he is aware, such a condition has not been described in the central nervous system. When the cavity is subjected to the close scrutiny of the highest power of the microscope, fine fibers which have the appearance of typical neuroglia fibers are seen to cross it. The few cells present are of this latter type also, but much larger than normal, showing numerous branching processes proceeding from a central area of protoplasm which includes the deeply stained nucleus. The nerve-fibers themselves are seen to have not only become atrophic, but to have absolutely disappeared, whereas in other parts of the nerve they can still be traced between the fibrous septa. Although the anatomic structure of the cavity is evident, its explanation is extremely difficult. Both Dr. Spiller and the writers, however, concur that it is probable that the area involved is one of rarefaction of tissue, in which for some unknown reason the atrophic process was not accompanied by the usual sclerosis of the connective-tissue fibers, whether of pial or neurogliar origin, and that, perhaps, to some extent the separation of the fibers, with the open spaces between, was increased by the process of hardeing and imbedding the eye. It is possible that the interfering process was a local edema, although the cavity does not present the appearance of a cyst. There are no traces of any previously existing exudate or hemorrhage to account for it, and the writers can only present the specimen as a unique condition without attempting further explanation.

In the second case, the absence of decided atrophy of the nerve, in conjunction with such extensive changes in the retina, is rather remarkable, but doubtless indicates that the detachment of this membrane was of recent origin.

In the third case, the point of greatest interest is the formation, in the old exudate, on the surface of the choroid, of the large cavities, which are lined with a single layer of cells. (Plate II.) These cavities vary greatly in size, the largest being 2 and 3 mm. long, and 1 mm. wide. On casual examination, they appear like enlarged lymph-spaces, lined with endothelium. More careful study, however, shows that these lining cells are pigmented, and that the pigment granules are in the form of the minute rods which are typical of the retinal pigment cells. Such cavities have been previously described and discussed by Krueckmann[1] in his article on pigment changes following ligation of the choroidal vessels. He thinks that they are due to the union of two separate processes of the proliferating pigment epithelium. The writers, however, believe that the method of their formation was different in this case. By studying a series of sections, it is possible to follow the process, from its inception to the formation of the largest cavities. As in every case of exudation on the surface of the choroid there has been a marked proliferation of the retinal pigment cells. These can be traced as single and double lines of cells, extending through the newly formed tissue. In places, the cells composing the double lines are separated by a narrow space containing a few blood-cells. Between these small spaces and the large cavities there are cavities of intermediate size, all of which are lined with pigment cells, while many contain loosely coagulated fluid, with a few red corpuscles and the leucocytes. From the subsequent shrinking of the tissue the process may be outlined as follows: Proliferation of the pigment cells, at first in a single layer, later in double layers. As a consequence of the subsequent shrinking of the exudate, these layers are pulled apart and interstices are formed in which fluid collects, and as the contraction of the exudate advances, and more fluid is forced into the laminæ, the latter become more and more distended and form the cavities which have been described. In their complete form, it is possible that they may act as true lymph-spaces, although lined with epithelium instead of endothelium.

THE THERAPEUTIC PROPERTIES OF THE SUPRARENAL CAPSULE.*

W. H. BATES, M.D.
NEW YORK CITY.

The curative action of the suprarenal extract, dealing with all inflammations of the body and with those diseases which are affected by changes in blood-pressure, covers a wide area of therapeutic application. If we are to use this drug, which is so rapid that its maximum effect is reached in less than one minute, and so potent that some obstinate cases of chronic keratitis have been cured in one treatment, it is imperative that we should know what effect the suprarenal extract, absorbed from its local use in the eye or ear, will have on other organs, since the patient may also have serious lesions of the heart, kidneys or other tissue. To obtain this necessary knowledge, I had at my command my own clinical observations, my laboratory experiments, and the experiences of physicians whose work lies in other fields. The conclusion drawn from these data is that no condition of organic disease contraindicates the use of suprarenal, non-septic solutions being absolutely harmless. Its constitutional action may be briefly described as a muscle tonic, restoring the power of contractility to all muscle fibers, especially those of the arteries and heart. The fact that the suprarenal is a muscle tonic, supplying what is one of the necessary components of muscle tissue, may also explain why it is not a poison. In dealing with a drug a small dose of which produces a powerful effect, we naturally expect a large dose to be an active poison, but the suprarenal is unique in that while one-tenth grain has produced the maximum physiologic effect, two ounces caused no further effect. It has been shown by physiologic experiments that the excess of the suprarenal supplied for muscle tissue is stored for future use. It is important also to remember that no result will follow the administration of it unless its use is indicated, and when indicated the benefit follows immediately.

---

[1] Archiv. f. Ophthal. xlviii, 2.

*Read before the New County Medical Association, May 21, 1900.

The suprarenal being a muscle tonic explains also its action in apparently opposite lesions of heart disease. The laboring heart, due to stenosis of the valves, is relieved by the suprarenal, as well as when it is due to insufficiency; and a dilated heart is benefited as much as a small one. When the pulse is of high tension, it becomes softer, and when the pulse is weak it is strengthened. Again, when the pulse is too rapid and weak, the suprarenal will retard and strengthen it, while a slow, weak pulse will approach the normal, and one irregular in force or frequency or intermittent will become regular. On the other hand, the strong pulse of a normal or diseased heart is not affected by the suprarenal.

When the peripheral vessels are contracted and the extremities are pale, the circulation is improved after the internal administration of the suprarenal, and in the opposite direction, when the peripheral vessels are dilated, with the extremities congested, the suprarenal is beneficial, giving tone to the heart and blood-vessels. It has a selective action for congested tissues; for example, the inflamed mucous membrane of the nose in acute rhinitis will be whitened after the internal administration of the drug, while the normal conjunctiva of the eye will remain unaffected.

When the aqueous solution of the extract is applied to mucous membrane, the parts are whitened in one minute, and a secondary dilatation of the vessels does not follow.

Dreyer[1] found that the secretion of the adrenals could be increased by electrical stimulation of the splanchnic nerves. I have observed, clinically, that the physiologic effects of the internal administration of the dried glands can be obtained in acute rhinitis by the use of electricity or counter-irritation over the dorsal and lumbar region, which suggests the possibility of an increase of the internal secretion of the adrenals.

Preparation and Preservation of the Aqueous Solution.—It should be mixed in a test-tube, taking one part of the dried powdered suprarenal to ten parts of a saturated solution of boracic acid, and held over a flame until it boils; then it should be filtered and the filtrate boiled in its permanent receptacle. A solution of the aqueous extract prepared by this method will retain its properties for months, and the whole process requires only about three minutes.

The solution is more active when prepared without the boracic acid, but I use the latter, boiling it daily to prevent decomposition.

Cautions in its Administration.—It is necessary to use freshly prepared solutions to obtain the best local effects, and if the drug is used in the form of a powder or emulsion, the excess should be removed to prevent infection. In severe nasal hemorrhage, it is difficult to reach the bleeding surface with the extract if applied by a spray or by cotton on a probe. In some cases, I syringe a 10 per cent. emulsion with force into the nares before the bleeding ceases. Tampons, wet with the extract solution, should not be left in the nose, because infection occurs in a few hours, with vascular disturbance and secondary hemorrhage. This warning should be emphasized, for I have seen one case with a temperature of 104 F., general pains and great prostration for three days from the use of a putrid solution of the suprarenal. When administered by the stomach, the active principle may be destroyed by alkaline fluids, so more constant results are obtained by placing the dry powder on the tongue and directing the patient to swallow it slowly when it becomes moist. The greatest care should be employed to obtain an aseptic solution when it is used hypodermically.

Eye and Ear Diseases.—The following are a few facts which I have noted in the treatment of the eye and ear: 1. The temporary effects of the suprarenal in inflammations may be made permanent by the use of other treatment. In some cases of acute infectious conjunctivitis, I have been able to cure the disease in one treatment by thoroughly cleansing the eyelashes and exterior of the eyelids with a 2 per cent. solution of carbolic acid, after the eye had been blanched by the instillation of suprarenal. 2. Excellent results follow a similar treatment of gonorrheal ophthalmia. 3. Cases of deafness which are not improved by the usual methods of treatment have been cured by the suprarenal in addition to other treatment.

Nose and Throat.—1. The suprarenal is invaluable in controlling hemorrhage after nasal operations, and I now perform major operations on the nose with very little hemorrhage. 2. By lessening congestion, so that other treatment will be efficient, the suprarenal is useful. I have cured acute rhinitis by the local use of the suprarenal, followed by a mild antiseptic. Quoting Dr. E. Mayer: "For these cases, the extract does wonderful things, and if it never had any other value it would have its mission in this alone." Dr. J. J. Griffiths cured four cases of acute influenza of the nose in one treatment. He used the dried powder locally, with a powder-blower. One case was infected, but recovery followed in six hours. 3. Chronic rhinitis is temporarily improved by suprarenal, and permanent results are obtained from the use of other treatment, the suprarenal being a valuable adjuvant. 4. The internal use of the suprarenal powder, gr. v., t. i. d., is beneficial in diseases of the nose and throat. 5. Dr. H. Holbrook Curtis has found the suprarenal of great value in laryngeal phthisis. Its local use relieves dysphagia better than cocain. He has also obtained benefit from its use in the acute laryngitis of singers, when the vocal chords were relaxed or congested.

Hay-Fever.—The suprarenal is a specific for this disease, being used locally and internally. Many patients who have suffered for twenty years with yearly attacks of hay-fever have been temporarily relieved of all their symptoms in five minutes by this remedy. Dr. Beaman Douglas[2] has recently written a very valuable paper on this subject. Dr. O. D. Pomeroy had such good results in treating ulcers of the cornea with it that he was led to use it in ulcers of the tongue and mouth with success.

Edema of the Glottis.—I am indebted to Dr. H. Boeker for the history of the following case of edema of the glottis, in which the suprarenal gave immediate relief: this is the third case on record, the first being published by Dr. S. S. Cohen: M. J. P., aged 30 years, during an attack of erysipelas of the face and neck, developed alarming symptoms in the throat. Late at night the doctor was hurriedly summoned to the patient, who could hardly breathe from the swelling of the throat. Six grains of the suprarenal were placed on the patient's tongue and he was directed to let them slowly dissolve in the saliva of the mouth. Five minutes later a decided amelioration of the threatening symptoms was noted, and an uninterrupted recovery followed.

---

[1] American Journal of Physiology, 1899.

[2] N. Y. Medical Journal, May 12, 1900.

A fourth case was successfully treated with the suprarenal by Dr. H. Holbrook Curtis, who believed that tracheotomy would have been necessary without it.

Hemostatic Properties.—If the suprarenal did not have any other striking properties, it would be remarkable for its hemostatic power alone. Bloodless operations on the skin have been done by means of the suprarenal used hypodermically. In cases of hemophilia, when other remedies failed, it controlled at once nasal and urethral hemorrhage. Secondary hemorrhage is not increased by its use. Hemorrhage may be controlled by its internal administration. In one case of intraocular bleeding, the extract controlled it and saved the vision. In a like manner, a case of severe uterine hemorrhage was controlled, and it was used with success in one case of severe hemorrhage in ulcer of the stomach.

Exophthalmic Goiter.—The cases improved immediately after the first dose; the circulatory disturbances, the tremor and thyroid enlargements became less.

Asthma.—Dr. S. S. Cohen[3] found the suprarenal of value in twelve cases.

Urethra.—Drs. Otto, Alexander and J. A. Moore find the hemostatic property of the suprarenal valuable in internal urethrotomy and in the treatment of urethritis.

Rachitis.—Stoeltzner[4] is the first to publish beneficial results from the suprarenal in rachitis.

Kidneys.—Dr. J. M. Otto reports two cases of interstitial nephritis very much improved by the suprarenal.

Heart Disease.—Physiologic experiments on dogs by Oliver and Schäfer have shown that the suprarenal is a most powerful heart stimulant. With .01 gm. of the fresh suprarenal the blood-pressure of a dog was raised more than twice its original height, while with .22 gm. of digitalis leaves no appreciable effect was obtained. They also obtained negative results with ergot.

Cleghorn, experimenting on the isolated dog's heart, found that the apical contractions were doubled by the suprarenal.

Exact knowledge of the properties of a drug can be obtained by laboratory experiment, and is usually more reliable than clinical observation. When both agree we are close to the truth.

Drs. R. W. Wilcox and C. J. Mooney noted the action of the suprarenal in the following:

M. S., aged 38 years, had general arteriosclerosis, with lesions of all the heart valves. The patient has been on exhibition in New York and other cities before classes of students in general medicine. His heart and circulatory phenomena are very interesting. The pulse was 90, of high tension and irregular in force and frequency. The patient was given gr. v of the suprarenal powder on the tongue, and ten minutes later the pulse was softer and more regular. The effect continued more than eighty minutes.

Dr. S. Floersheim treated 15 cases of heart disease with a mitral regurgitant murmur, with the extract, in which he noted: 1, a weak pulse became stronger; 2, a high-tension pulse became softer; 3, an intermittent pulse, or one irregular in force and frequency, became regular; 4, a dilated heart was contracted; 5, the normal heart-sounds were more distinct, while the initial regurgitant murmur became less audible. He is the first to call attention to this phenomenon; 6, the suprarenal produced no apparent effect when the pulse was strong in the normal heart or in organic heart disease.

Reports of cases confirming these observations have been sent to me by Drs. J. M. Otto, G. W. Kelly, A. A. Wolfe, E. C. Bennett, G. A. Rogers, J. J. Griffiths, C. D. Jones, John Clark, P. W. Barber and George B. Fowler. These observers have also found that the suprarenal has stimulated the heart after other well-known remedies had failed.

The suprarenal has proved to be my most valuable remedy in the treatment of the eye and ear. I find indications for its use in the majority of my cases; and with increasing experience, I am extending its therapeutic application. My results have been confirmed, and in other hands its usefulness extended, even beyond my very sanguine expectations. This is noteworthy when we remember the unusual properties of the active principle: 1, we have found no element or compound which may be added to it in solution without impairing its activity; 2, decomposition occurs in a solution which has not been sterilized, and the administration of an infected solution is very dangerous.

When we remember the difficulty of impressing on commercial chemists and practicing physicians new methods of procedure, it is remarkable that so few have been disappointed in the results of their use of the suprarenal extract.

50 East 64th Street.

SCROFULOUS KERATITIS.

OBSERVATIONS ON ITS ETIOLOGY, AND ITS TREATMENT, ESPECIALLY BY SALICYLATE OF SODIUM.*

H. GRADLE, M.D.
CHICAGO.

Under the head of scrofulous or lymphatic keratitis, or kerato-conjunctivitis, many writers include several forms of disease besides typical phlyctenules and the infiltrates into which they may change. These are the various forms of superficial vascular, marginal keratitis, known as phlyctenular pannus and fascicular keratitis, as well as some plastic or papular vascular tumefactions at the corneo-scleral margin. It is characteristic of these different types that they occur only in children, or if in adults, only in those who have had more or less continuous attacks of corneal disease since childhood. It is less commonly known that in the earlier attacks of this form of disease the phlyctenular type prevails, and that the various vascular and plastic lesions are only seen at later periods.

The term scrofulous was applied by the earlier observers, because these diseases are mostly seen in typically scrofulous children. This fact has been less emphasized in recent literature, perhaps because the diagnosis of this latter condition scrofula has lost much of its former scope, and is now in a transition period. Many of the attributes and symptoms formerly referred to it we know now to be coincidences of secondary importance. The eye disease itself, formerly ranged as evidence of scrofula, does not occur in every scrofulous child. Suppurative otitis, once considered a classical symptom, we now know to be an accidental pyogenic infection. The nasal symptoms and their consequences, for instance, the thick lips, are the results of enlargement of the pharyngeal tonsil, which is common but not constant in scrofula, and which, too, can occur without any other sign of scrofulosis. Even the eczema, so typical of it, is not always present and occurs as well in non-scrofulous individuals.

---

[3] The Journal, May 12, 1900.

[4] Jahr. f. Kinderheilk., 1900, No. 1.

*Presented to the Section on Ophthalmology, at the Fifty-first Annual Meeting of the American Medical Association, held at Atlantic City, N. J., June 5-8, 1900.

What is left, then, of the clinical conception of scrofula? The only practically constant lesion is the presence of enlarged lymph-glands, usually cervical, and with it a more or less evident degree of malnutrition, whence the liability to the aforesaid complications.

Clinical observations, and more especially autopsies, show that the most common lesion of the enlarged lymphatic glands in childhood is tuberculosis. In fact, this seems to be the invariable condition whenever the clinical diagnosis of scrofula can be made. Even if the tangible cervical glands are not involved, tuberculosis is found in the deeper parts of the lymphatic system, as the bronchial glands. The identity of scrofula with tuberculosis of the lymph-glands has been even more fully established on a large scale by the results of diagnostic injections of tuberculin, as reported from the Berlin Institute of Infectious Diseases by Petruschky and by Beck, and in this country by Otis.

It is well known that the phlyctenular and allied types of corneal disease occur mainly in distinctly scrofulous individuals. It can also be readily observed that the more severe and rebellious forms of keratitis coincide with the most pronounced general manifestations of scrofula. The question, therefore, occurs whether these forms of eye disease are not by themselves evidence of the existence of a tubercular focus somewhere in the lymphatic system. I do not mean that they are tubercular lesions due to the presence of the tubercle bacillus. But the conclusion seems to me well founded that these types of keratitis occur only in individuals under the influence of poisons produced by the tubercle bacillus in one or more lymph-glands. The occasional rare observation of the eye disease in apparently non-scrofulous subjects is more logically explained by the existence of a small hidden tubercular focus than by assuming them to be exceptions to an etiological relationship so well established by clinical experience.

The accuracy of this view could be proved by a continuous series of tuberculin injections. Personally, I have only been able to make this trial four times—always with positive febrile reaction, two of these being apparently non-scrofulous children. This number is, of course, altogether insufficient for generalization.

The direct exciting cause of phlyctenules is not known. The search for bacteria by Gifford, Bach, Axenfeld and others has given negative or inconstant results. Regarding the direct etiology of the other scrofulous manifestations on the cornea we know even less. Clinically, however, it can be observed that there are a variety of lesions adjoining the eye which often precede the corneal, or conjunctival, disease, while in other cases their presence seems responsible for relapses or protracted persistence of the eye lesion. The hypothesis of their apparent influence is mainly based on therapeutic results. While these are often more or less ambiguous, still, a sufficiently extensive observation shows that in many of the more rebellious instances of the eye disease the cure is favored and the liability to relapses diminished by the elimination of these concomitant lesions. Although this connection is discussed in some of the text-books, especially fully by Fuchs, it is ignored in others, and often, too, in practice. These unfavorable concomitant lesions are the following:

Catarrhal conjunctivitis of the eyelid—itself always a secondary complication—may protract the corneal lesion until it is cured by nitrate of silver. More serious even than diffuse catarrhal conjunctivitis is the hypertrophy of the upper retrotarsal fold, the "Schwellungs-katarrh" of German writers. This is not always accompanied by catarrhal secretion. In this form I have often used strictly localized applications of 10 to 25 per cent. solutions of nitrate of silver with benefit, when weaker solutions failed. Ulcerative blepharitis—not a rare complication, may help to maintain the corneal disease until checked by the nitrate of silver stick. Eczema of the eyelids or face has been noted by Continental writers as such a frequent complication that the term eczematous kerato-conjunctivitis has been largely accepted. In observations in this country this coincidence is not so common, although sufficiently frequent. That eczema exerts an unfavorable influence upon the duration of the eye disease and increases the chances of relapse can be definitely inferred by comparing the history in long-standing cases before and after the successful cure of the skin disease. It has likewise been noted that the presence of lice in the hair may exercise a similar prejudicial influence.

Relapsing phlyctenular eruptions are in some few instances preceded every time by a sudden, but subacute, nasal catarrh, so that the latter may be properly suspected as the direct starting-point of the eye disease. This definite relationship has not been a frequent one in my observation. Much more common is the secondary occurrence of the typical form of scrofulous nasal catarrh—a subacute rhinitis with characteristically thin seropurulent secretion, causing erosions and eczema at the entrance to the nose. I am not positively assured by my therapeutic experience how much influence this nasal disease has upon the ocular lesion. It is a very frequent coincidence, and its treatment has sometimes seemed of decided benefit to the eye; but in other instances no such influence was observed. Regarding another very common nasal coincidence, viz., enlargement of the pharyngeal tonsil, I can say positively that its removal lessens the liability to ocular relapses, but that it has not seemed to benefit the existing ocular lesion in any very striking manner.

In judging the etiologic relationship of the aforesaid complications to the eye disease on the strength of therapeutic results, it is, of course, essential to know what the local ocular treatment would have accomplished by itself. In fact, my most positive conclusions were obtained in those cases in which proper local treatment has previously been exclusively relied upon by some other surgeon.

Regarding the efficacy of local treatment, I believe I can add an item to the mooted question as to the advisability of atropin. In all forms of corneal disease in which the ciliary injection is strictly localized to the quadrant of the lesion the use of atropin is irrelevant and unnecessary. Its subjective and objective influence is generally apparent, however, whenever the ciliary injection is diffuse, especially in the case of deep lesions. The more superficial the process the less the beneficial effect produced by atropin. The influence of atropin upon the disease can also be judged by the reaction of the pupil. Prompt dilatation shows that nothing will be gained by continuing its use, while resistance to dilatation may be stated as a definite indication for its further use.

In spite of appropriate local treatment and attention to existing complications a small number of cases of scrofulous keratitis prove very refractory. I do not refer, of course, to typical phlyctenules, as these are always transient lesions, although they may be followed by very persistent localized infiltrates. Apart from these infiltrates it is essentially the more extensive lesions of later attacks which may continue and extend, notwithstanding proper care. It is for this class of cases that I can recommend salicylate of sodium internally. I have only used it when all other treatment had failed to influence the disease after a trial of reasonable duration—altogether in about twenty instances. Of these one-fourth were not influenced perceptibly, in three the results were either transient or a mere coincidence, while in more than one-half of the cases an unmistakable improvement in the subjective and objective condition was obtained within forty-eight hours. Large doses are required, one to one and one-third grams every two to three hours for an adult; two-thirds of a gram at a dose for a three-year old child, perhaps four times per day. Ringing in the ears or depression may enforce a temporary interruption. Small doses are useless. The remedy is best tolerated in the form of tablets—five grains. If no influence is perceived after the steady use during two days, it is useless to continue it. In favorable cases it may be omitted on trial after a few days. Sometimes the recovery will continue at the same rate, in others it is best to resume the drug. In a few instances in which prompt effects were obtained at first the remedy seemed to lose its influence after a while. There is hence nothing specific in its action. Its influence was most pronounced in the cases accompanied by much suffering. The form of the disease over which it had the least control was the circumscribed post-phlyctenular infiltrate.

DISCUSSION.

Dr. J. L. Thompson, Indianapolis—I have met with a great many of these cases, but they did not all occur in scrofulous patients by any means. In our section of the country I should think we have about ninety-nine out of one hundred of these cases occurring in hot weather, very frequently in the early spring, but if we have intelligent patients whose parents are able to take them to a cooler region for a short time they are usually all right after a few days. The parents will often write in a short while that Johnnie or Mary is well and ask if they can be brought home. I tell them to stay in the north. They must also be careful of the diet, for if they take excessive quantities of cakes and candies they may expect to have the trouble for a long time. Fresh air is, however, most important. These cases may appear first as herpes or eczema, and if kept in close, hot quarters all the treatment on earth will not relieve them. I have had cases of this kind occur in adults, and many people after an attack of migraine immediately have one of these phlyctenules of the cornea.

Dr. Robert Sattler, Cincinnati—I would like to ask Dr. Gradle whether he supplements the internal treatment with sodium salicylate by the use of any local measures, such as curettement, etc.?

Dr. S. D. Risley, Philadelphia—I would like to recall once more the history of a case that I related to this section several years ago, of a child that had been tormented by attacks of phlyctenular keratitis in successive summers, each attack being very persistent. They finally ceased to recur, and many years later this child was brought back to me at the University Hospital clinic with a hunched back, interstitial keratitis and Hutchinson's teeth. The early attacks presented all the characteristics of phlyctenular keratitis, but they evidently had a basis of inherited syphilis, which had sapped the vitality of the child.

Dr. A. W. Calhoun, Atlanta, Ga.—The speaker did not mention the use of protargol, or any of the astringents. In the abundant experience in the section I come from, where this disease is common among colored people, the parents are found to be of tuberculous habit very largely. During the last winter I have experimented with protargol with very satisfactory results. The ordinary treatment would have very little benefit, but in a number of instances I have used this remedy in 1 per cent. solution with good results, applying it directly to the ulcerated surfaces. I can bear testimony to the use of sodium salicylate internally at the same time.

Dr. A. R. Baker, Cleveland, Ohio—For many years I have looked upon phlyctenular ulcers of the cornea as being due largely to digestive disturbance, and I found that as long as I treat the eye alone I do not succeed in curing my cases. In fact, I think I got the idea from seeing many cases that had failed under treatment by some oculist go back to their family physician and get well after he had treated their digestion. So I have for a long time commenced the treatment with a few doses of calomel and soda, and followed that with iron, arsenic and strychnia, and in addition to that given almost exclusively milk diet. Many of these children would not get well at home, because their parents indulged them, but would recover rapidly in the children's hospital, and whenever we can regulate the diet and send them to the country, perhaps to some of the country homes for children, they get well and remain so. I have come to look upon these cases, then, as largely cases of disturbed digestion, and pay very little attention to the local treatment of the eye itself.

Dr. A. D. McConachie, Baltimore—I rise to endorse the last speaker's statement. My experience has been much the same, and I believe it has come to be a standing joke, among my confrères who listen to me in the Presbyterian Dispensary work, that I lay very little stress on the local treatment. You must be emphatic with the parents in speaking of the dietetic treatment. In fact, I think it would be well if we could make out printed instructions to apply to these cases. Just a few days before I left home the father of one of these sick children said to me: "I guess it will not hurt the child to eat bananas?" I asked how many he ate a day, and the father replied, thirteen; the child was only 3 years old. I would be a little afraid of the action of sodium salicylate on these children, whose stomachs are already disturbed. I believe 99 per cent. of these cases will get well without local treatment, but in some cases I have used ichthyol in conjunction with the usual collyria, with very great satisfaction. The removal of adenoids, when present, is most essential. Many of these cases are accompanied by nasal catarrh, which should receive appropriate treatment.

Dr. John S. Kirkendall, Ithaca, N. Y.—I quite agree with all these gentlemen as to the influence of the treatment that they have described. But there is one very important factor in most all these cases, especially the obstinate ones, which they have overlooked, or omitted, and that is the presence of nasal growths, adenoids, etc. I believe that these phlyctenular cases are infectious, and that the nasal secretions are the causative factors. I have found this true in almost every case, and by the removal of the tonsils and adenoid growths, and by the use of the spray, and all possible means to prevent this nasal secretion from coming in contact with the eyes, I have not failed in any case to prevent the corneal scars which are the result of prolonged attacks of this trouble.

Dr. G. A. Aschman, Wheeling, W. Va.—Even fifteen or twenty years ago it was acknowledged that there were different etiologic factors in this disease and we must consider it in selecting the proper treatment. It is true, I believe, that the majority of these cases come from digestive disturbances, but undoubtedly in those cases where nasal conditions are the cause, there is some influence on the fifth pair of nerves, as there is in the cases that take on the herpetic form. I should imagine that in those cases the sodium salicylate would be of benefit. I think, however, it is absolutely necessary to consider the etiology in every case.

Dr. John Chase, Denver—For a number of years, in talking with students, I have summarized the subject by suggesting to them that they have to deal with an unhealthy animal, and that success or failure will follow according as they realize this. The lack of good red blood-corpuscles is frequently the cause of the condition. If possible I have these patients sent to the country and beg or cajole them into the use of proper diet.

DR. ALBERT E. BULSON, JR., Fort Wayne, Ind.—I want to say a word about the use of sodium salicylate in these cases. For a time I thought it very efficient as a constitutional remedy in phlyctenular keratitis, but I used it as an adjunct to dietetic and hygienic measures. I soon found, however, that my cases improved just as well without the salicylate treatment, and in many cases a great deal better; the salicylate only aggravating the stomach derangement, which is almost invariably present. I want to endorse what has been said regarding the cause of the disease being essentially one of bad dietetic and hygienic conditions. Good, but plain food, regularly administered, and an abundance of fresh air, are as essential as medication in the treatment of phlyctenular keratitis.

DR. L. J. LAUTENBACH, Philadelphia—Since a year or two ago, by using a very simple method for removing adenoid growths I feel more ready to go into the pharynx and work, and I rarely see a case of this kind in which I do not examine the throat. In a large proportion, probably 40 or 45 per cent. of these cases, I find a growth present, and I believe that these are not all cases of indigestion, but rather of specific affection, or some deep systemic disorder of which these manifestations are but symptoms. These may be readily separated, however, from the ordinary phlyctenular cases, although I will not here give you the exact lines of demarcation. I believe in hygienic treatment in these cases, of course, but as a rule in the cases I have received the general practitioner has already looked after that part of the work. It is sometimes wonderful to note the effect of removing the adenoids. In this special class of cases I frequently use cod-liver oil. It seems to be almost a specific. I think that these phlyctenulæ represent two or three separate and distinct diseases, and it is for us to distinguish each from the other, make the diagnosis accurate, and treat them accordingly.

DR. H. V. WÜRDEMANN, Milwaukee—In my experience, phlyctenular keratitis is simply a symptom of some one of many diseases. It is rarely a symptom of local infection. It may be a symptom of a disease within the air-passages of the nose and pharynx, or much more commonly, an evidence of systemic dyscrasia. Each case is a special study, and, besides the general treatment, we must search out the local cause, as it is only by a combination that we succeed in a cure of this very common affection.

DR. LEARTUS CONNOR, Detroit—There are a vast number of children who have indigestion, and of this number relatively few have the disease we are now discussing. There are a vast number of children who have diseases of the nose and adenoid tissue of the nasopharynx, and of that number, as my observation goes, but relatively few have this disease, and so I think it is rather illogical to say that either one or the other of those conditions produces phlyctenular keratitis. I suspect myself that the truth will be that these conditions we have been alluding to are supplemented by some sort of a local irritation or infection. I have myself observed it come on in persons thus reduced by exposure to a strong wind or to dust, infected air, and other local causes. While it is true that it is necessary to make the child a healthy animal by the use of outdoor exercise, attention to the diet, etc., the local treatment is extremely useful, and I rise to say that as the result of observations made during the last year, I have found that after the general conditions are made right the use of protargol solution, even in larger doses than Dr. Calhoun uses, has been very satisfactory. I do not neglect the use of atropin, which I regard as essential. I use protargol in strength as great as 30 and even 60 grs. to the ounce.

DR. FRANK ALLPORT, Chicago—Amongst the other causes of phlyctenular keratitis I desire to remind the section of the process of teething. I have recently seen a baby who had a phlyctenule every time a tooth appeared, and I soon learned that the first thing to do was to lance the gum, which usually quickly relieved the eye trouble. There is one point in regard to the treatment that I am surprised no one has mentioned, and that is the cauterization of the ulcer. I find great satisfaction in cauterizing each one of the little phlyctenules as they appear, with a 95 per cent. solution of carbolic acid, applied on a small probe, protected with cotton. I commence the treatment of all my cases with this and follow it with the local and constitutional treatment already described by so many.

DR. HIGGINS—I want to inquire of the writer of the paper if he has not noticed, among all these causes, eye strain as a cause? I have paid some attention to this, and whenever I have one of these little patients come in, and they are generally of that age where they are just beginning to use their eyes, I request the parents to bring them back when the eyes are well enough to test the refraction, and I have usually found some refractive error.

DR. R. L. RANDOLPH, Baltimore—I would like to ask Dr. Gradle if he has succeeded in getting any good results in ulcers of the cornea without the use of atropin, and I would also ask what strength of protargol solution he uses? It has always seemed essential to me to use atropin.

DR. A. W. CALHOUN, Atlanta—The strength of protargol solution I have used ranged from 1 to 5 per cent.

DR. LEARTUS CONNOR, Detroit— I have used it in from 20 to 60 grains to the ounce.

DR. GRADLE—The object of my paper was, in the first place, to raise the question whether every instance of phlyctenular keratitis or the other allied varieties of keratitis depended upon a tuberculous diathesis. It seems I did not express myself very clearly, for the discussion has wandered off from that subject. The question itself, I am not in a position to answer absolutely. We can do that only by making a continuous series of tuberculin injections in a number of unselected cases. A great many other data, however, point strongly to the idea that a tuberculosis of some lymph-glands is the indispensable condition. At the time of the Denver meeting I was assured by several of the local oculists that this form of trouble was comparatively rare in Colorado, just as tuberculosis is.

I also mentioned a number of accessory conditions, which could not, however, be called causes. I fully agree with Dr. Lautenbach on the importance of treating adenoids, which are present in a large majority of cases, but these are in themselves suspicious of the existence of tuberculosis in the body; just as these forms of keratitis, though not due to the presence of the tubercle bacillus in the eye, depend in my judgment on the existence of some focus in the body for the elaboration of the poison. As to the question of disturbed digestion, I did not touch on that because I did not intend to discuss all the phases of the treatment. I am of the opinion that the deranged digestion is often but an expression of the hidden tuberculous diathesis.

As regards treatment, Dr. Randolph's question about the use of atropin is answered in my paper. I do use it in phlyctenular and scrofulous troubles, provided the injection is not strictly localized, but diffuse, and provided the lesion is deeply situated in the cornea, and I do not continue it if the reaction of the pupil to atropin is very prompt. I did not refer to ulcers at all, and do not feel called upon to answer any of the discussion regarding them. The ulcer is a secondary occurrence, probably due to secondary infection, and is not specific. I was asked if I used local treatment. I have been in the habit of following out all the treatment laid down in the text-books, sometimes with good, sometimes with indifferent results. I used the sodium salicylate in the cases not amenable to local treatment and hygienic care. When we get a papular tumefaction at the corneoscleral margin it may last weeks and months, and it requires every effort on the part of the oculist to combat the suffering of the patient and to end the disease as quickly as possible, and for this purpose I recommend sodium salicylate. I would not think of using it in transient cases, nor until the local treatment had been fully tested Phlyctenules will usually take care of themselves in a few days without any treatment.

VOLUNTARY notification of phthisis to the health authorities of Plymouth, Eng., is rewarded by a fee to the medical practitioner of a half-crown in case of private patients, and one shilling in case of parish or dispensary patients.

FRACTURE AND DISLOCATION OF THE SPINE.

WITH REPORT OF CASE OF GUNSHOT WOUND OF THE SPINE.*

S. P. KRAMER, M.D.
Professor of Pathology and Clinical Surgery at Cincinnati College of Medicine and Surgery; late Major and Brigade Surgeon, U. S. V.
CINCINNATI, OHIO.

Gunshot wounds of the spine in which the bullet entered from the abdominal surface are of sufficient rarity and the results attending their operative treatment are of sufficient interest to justify the report of the following case:

"Mrs. X., seen on March 13, 1896, presented a pistol wound 2, 1896. On February 26, 1896, the patient was shot in the abdomen with a 38-caliber Smith & Wesson revolver, fired at close range. Immediately after the injury the patient sank to the ground, vomited blood, but did not lose consciousness. It was very soon noticed that she had lost both sensation and motion in the lower extremities and that there was retention of urine and feces. At the time of the injury the patient was six months pregnant. She aborted next day and did not menstruate after that. Dr. Cartledge, of Louisville, who saw the patient about two weeks after the injury, has kindly furnished me with the following data:

"Mrs. X., seen on March 13, 1896, presented a pistol wound in the epigastric region, about two inches below the ensiform cartilage, and three-quarters of an inch to the left of the median line. There was a history of a vomiting of blood within a short time after the injury, also immediate and total paralysis below a point corresponding posteriorly to the shot wound on the anterior surface. The general condition was fairly good. The abdominal wound displayed nothing more than the signs of a slight localized peritonitis of traumatic origin."

In a short time extensive bed-sores had developed at the points of pressure, and great pain was experienced in the upper half of the body, radiating toward the shoulders. Morphia was administered to relieve this pain, in such increasing doses as to beget the habit, so that at the time of entrance, the patient was taking twenty grains hypodermatically per diem. On July 5, 1896, I saw her for the first time, in consultation with Dr. J. T. Whittaker. I found the patient an exceedingly delicate, nervous woman, greatly emaciated, with a drawn expression of countenance. The urine was being drawn with a catheter, was strongly decomposed, and there was undoubtedly a severe mucopurulent cystitis present. She had no evacuations of the bowels except such as were produced by glycerin enemata. On the anterior surface of the abdomen, two inches below the tip of the ensiform cartilage, and three fourths of an inch to the left of the median line, was found a cicatrix marking the point of entrance of the ball. Powder-marks were about the scar showing the short range at which the pistol was fired. At all points of pressure, over the sacrum, the trochanters, the inner surface of the knees and ankles, extensive bed-sores had developed. In some places the bone was denuded. The edges were livid, the discharge was copious, and there was no sign of healthy granulation. There was complete motor paralysis of both lower extremities, spastic contracture of the flexors of the leg and adductors of the thighs. Sensory paralysis extended to the level of the ninth dorsal vertebra posteriorly on the right side and to the eighth dorsal on the left side; anteriorly to free border of the ribs. There was no response to the faradic current on the part of the muscles of the leg. Patellar tendon reflexes were absent. The patient was evidently becoming septicemic. She had had chills during the past week and the temperature ranged from 99 in the morning to 102 in the afternoon. With this history there could be no doubt that the bullet had pierced both walls of the stomach, had passed into the spinal column, and had either divided the cord or was interfering with its function by pressure. Three attempts were made to exactly locate the ball with the Roentgen rays. On July 20, a negative was obtained which showed a dark spot in the spinal column on the left side, and on a level with the ninth dorsal vertebra. This was evidently not the bullet, since this would have made a slight shadow on the negative, but taken in conjunction with the extent of the paralysis, the point of entrance of the ball, and the fact that the stomach had been pierced, I felt that this dark spot was due to the destruction of bone at this point. The question that presented itself was the advisability of operating. The sudden and complete paraplegia, the absence of reaction to the faradic current and the extensive trophic changes seemed to indicate irreparable damage to the cord. Yet all of these might be caused by pressure, the relief of which would perhaps result in restoration of function. The patient was rapidly succumbing to septicemia, the case was otherwise hopeless, and at the earnest solicitation of the patient and her family, I decided to operate. She had developed on the anterior surface of the chest and abdomen a dermatitis from the effect of the X-rays. On July 21, 1896, the patient was anesthetized and laminectomy performed. I removed the vertebral arches of the eighth, ninth and tenth dorsal vertebræ. The dura was found to be uninjured; the cord felt soft to the touch. The dura was opened and the cord examined. The vessels of the pia were dilated, the cord soft and seemingly atrophic. There were no signs of a scar. The dura was then temporarily closed with forceps, loosened from its attachments to the canal, and the theca and cord drawn to one side. On passing the finger up and down along the anterior wall of the spinal canal, the conical point of the bullet could be felt projecting into the canal about one-third of its length, the other two-thirds being imbedded in the body of the ninth dorsal vertebra, a little to the left of the median line. On either side of the bullet was a spicule of bone projecting into the canal. The anterior surface of the theca was seemingly uninjured. The dura and cord were held aside, the bullet dislodged and extracted, and the displaced pieces of bone also removed. The theca was not sutured, the muscles and skin were drawn together by silkworm sutures and a strand of silkworm gut placed in the wound for drainage. The first dressing was removed on the seventh day. Primary union with the exception of two stitch-hole abscesses was found; union was complete at the end of eighteen days. On July 31, six days after the operation, the skin reflexes were marked, the knee-jerks still absent. The constipation was much relieved, the fever had disappeared. The sensory and motor paralysis and the retention of urine were as before. The pain was much diminished and the daily dose of morphia had been reduced to three grains. On August 22, the operation wound having completely healed and the bed-sores remaining unchanged, the patient was placed in a permanent bath. It was hoped that thus by relieving all pressure and by the continual cleansing of the sores they might heal. Fever was absent. September 10 the patient was still in the bath; the bed-sores were healing nicely. The X-ray dermatitis, which had resisted other treatment, had subsided. Patellar tendon reflexes were present on both sides. The skin reflexes were marked, This condition continued until October 6, and the patient was removed from the bath. The bed-sores had filled up and some of them were covered with epidermis. October 10 she had a chill, and the temperature in the evening went to 102. The cystitis was increasing in severity. October 20 the right leg was edematous, probably due to thrombosis of the vein. The sepsis was increasing. November 24 death resulted, probably from pyemia. An autopsy was not obtained.

There are several points of interest in the case, the discussion of which may be of some benefit. In the first place, the recovery of the gunshot wound of the stomach speaks much for conservative treatment in such cases. The recovery was probably largely due to the fact that the organ was empty at the time of the injury.

There is no injury which the surgeon is called upon to treat that is a source of so much solicitude and difficulty, both to himself and the attendants, as a fracture or dislocation of the spine accompanied by injury to the cord. We have all of us seen the picture of a once strong man dying by inches of sepsis from a paralyzed and infected bladder and from suppurating bed-sores that laid bare the bones of the pelvis. He lies there on his bed of suffering, a helpless and hopeless paralytic, a burden to himself, his loved ones, and his physician.

---

*Read before the Cincinnati Academy of Medicine.

The difficulties begin at the very inception. A careless movement in carrying the patient to his home may produce a very disastrous laceration of the cord. He must be moved with the very greatest care. For the same reason, all diagnostic manipulation must be interdicted. The diagnosis can usually be made from the history, inspection and the extent of the paralysis. The very greatest care is rarely successful in preventing extensive bed-sores. The most scrupulously aseptic catheterization will rarely prevent a disastrous cystitis.

But all of these complications are only symptoms. The grand question that presents itself is: Can not something to be done to restore the function of the cord, destroyed or interrupted by the injury? The surgical measures for the relief of this condition are of two kinds. The one, non-operative, consists of extension and contraextension, with the hope of reducing the deformity and relieving pressure on the cord. The other is an operative procedure, which has for its object the removal of the spinal arches at the site of the lesion, the inspection of the contents of the spinal canal, and the removal of any pieces of bone, foreign body, or blood-clot, which may be impinging upon the cord.

Much can not be said in favor of the non-operative procedure. Extension can do very little good, and may do a great deal of harm. A piece of bone that is not impinging may, by the movements of extension, be driven into the spinal marrow. On the other hand, it is purely a matter of accident whether or not a fragment that is causing compression may be drawn out of the way. One can never tell whether good or harm will be done by extension. Further, the extension can not be maintained, because the pressure of any apparatus or jacket upon the paralyzed parts is attended with destructive decubitus. It is very probable that the results that have been ascribed to extension would have also been obtained in those cases by rest in bed.

To my mind, extension is attended with too great risk to be recommended as a routine practice. On the other hand, the operative treatment is also a debatable procedure, and in taking up this question it is wise at the outset to consider the various lesions of the cord that may be brought about by these spinal injuries. One of three conditions may be present.

1. The spinal cord may have been completely divided; or it may have been crushed in such a manner that while there has been no actual division, a portion of the cord has been transformed into a disorganized pulp. In many of these cases, after producing this damage, the displaced bones return to nearly their normal position, so that there is little, if any, appreciable narrowing of the spinal canal.

2. The cord may be compressed by displaced fragments of bone or foreign body, the destructive lesion being of minor importance.

3. Pressure on the cord may be due to hemorrhage.

Where the condition is largely due to pressure, either by bone, foreign body or blood, the results following the early relief of this pressure will probably be very favorable. The mass of evidence goes to show that cord tissue once destroyed is never regenerated. But it is very difficult to determine beforehand in a given case how much tissue has been destroyed and how much of the functional disturbance may be relieved by the removal of pressure. Immediate and continuous paralysis has been held to indicate, as a rule, irreparable injury to the cord, either by severance or pulpification. Yet there are a few fortunate exceptions to this rule reported which still leave sufficient justification for operative procedure in these cases. Schede[1] reported a fracture of the fifth and sixth dorsal vertebræ followed by complete sensory and motor paralysis of both lower extremities, with absence of patellar reflex on both sides and the development of bed-sores the next day. Sixteen hours after the injury he operated, and found the dura uninjured and the cord soft and pulpy to the touch. He removed the fragments of bone found pressing on the cord and left the theca unopened. Two days after the operation the patient's condition had improved. The patellar and superficial reflexes had returned, and there was no ankle-clonus on the right side. At the time of the report the bladder and rectum were normal, the paralysis had disappeared and the patient walked without support.

Hammond and Phelps[2] report a similar case of fracture of the twelfth dorsal vertebra, with paraplegia, absence of patellar and plantar reflexes on both sides and of the cremasteric reflex on the left side. The operation was performed nearly two years after the injury, and two months later the patient walked without the aid of crutches.

While there is no evidence which proves that regeneration of the nervous elements of the cord occurs after total destruction, it must be borne in mind that every trauma produces areas of different degrees of injury to the parts involved. In addition to the elements that have been totally destroyed there must be such as have been injured, but not beyond repair. Such partial injury will result in complete death if the offending body be not removed, or perhaps in recovery if the relief from pressure restore the normal circulation, and if the further injury be prevented by the removal of the body in question. I believe this to be a very important consideration, and one that has for its logical sequence, not only the operative procedure, but also that this be done as soon after the injury as possible. If the offending piece of bone, bullet or blood-clot be allowed to remain, very grave secondary conditions may occur in portions of the cord that at the time of the injury may not have been irreparably damaged. These secondary changes, that are known under the term of compression myelitis, may set in very rapidly. They have been recognized as early as the fourth day. They lead to further destruction of the nervous elements of the cord, which are replaced by connective tissue. When this has occurred, restoration is, of course, impossible. There is no tissue that is so susceptible to circulatory disturbances as the spinal cord.

In recent years clinical evidence has been accumulating which goes to prove that operative procedure for injury to the spinal cord should be undertaken as early as possible. The old expectant plan of treatment holds out but little hope. In some cases pressure symptoms have subsided after a few weeks in bed, and the patient's condition had been somewhat improved.

And yet we can not say that even these patients would have been injured by an operation. The improvement might have been accelerated and increased thereby. The operation, per se, with the modern aseptic methods is not a dangerous one, while the advantages following the early removal of compression are manifest. I sincerely believe that unless considerable and continuous improvement sets in very soon after the injury, the greatest hope for the patient lies in an early operation.

In the following case very gratifying results followed the operation for relief of pressure.

---

1. Annals of Surgery, vol. xvi, p. 221.
2. Journal of Nervous and Mental Diseases, 1893, p. 478.

C. A. F., male, aged 35, admitted to Military Hospital, No. 2, Havana, Cuba, April 13, 1899 at 12 m. About two hours before admission he had fallen down a shaft a distance of about twenty feet. He did not recall exactly how he alighted. Immediately after the accident he was unable to stand, and complained of pain in the back and abdomen, especially when moved.

Examination revealed minor bruises about the body, motor paralysis of both the lower extremities. The power of internal rotation of the thighs was retained; he had control of the abdominal muscles.

Patellar, plantar and cremasteric reflexes were absent on both sides. The abdominal reflexes were present but apparently diminished. The bladder and rectum were paralyzed; there was retention of both urine and feces.

Analgesia of the legs and feet extended up to the knee. In this area, however, he had still the sense of pressure, but a loss of the sensation of heat and cold.

The next day the conditions were unchanged, and in addition he complained of considerable pain, girdle in character, in the back and lower abdomen.

On April 16 I was able to test the muscles of the leg with a faradic current and obtained some reaction. Galvanic tests were impossible. There had been no movement of the bowels since admission and no voluntary evacuation of the bladder. At 3 p.m., April 16, about seventy-seven hours after the injury, the operation of laminectomy was performed. The arches of the twelfth dorsal and first lumbar vertebræ were removed. The arch of the twelfth dorsal vertebra was found pressure upon the cord. There had evidently been a dislocation of the twelfth dorsal forward, with perhaps a fracture of the first lumbar, so that the cord was pressed between the body of the first lumbar and the arch of the twelfth dorsal vertebra.

The dura mater was not opened. There was no apparent hemorrhage, the cord being quite firm to the touch, with no perceptible injury. Six days after the operation he passed his urine voluntarily, and had a voluntary movement of the bowels. Three bed-sores about the size of a silver dollar had developed over the sacrum and tuberosities. On the 26th a considerable increase in muscular power was noticed; he could flex the thighs on the abdomen, and the leg on the thigh. The wound had healed by primary union. From this time on his condition constantly improved, the motor control of his lower extremities gradually increasing in extent and power. The extent of the analgesia had markedly diminished. On May 6, 1899, the patient was discharged from the hospital and took passage on board the steamer to return to Lancaster, Pa. His condition on the date of discharge was as folows:

Evacuation of the bowels was regular and under full control; micturition was voluntary, and under control; there was a slight cystitis present. There was analgesia extending over both feet and ankles and reaching half-way to the knee.

He had flexion, extension, adduction and abduction of the thighs, flexion and extension of both knees, and some slight extension of both toes on the right side, otherwise the muscles below the knee were paralyzed. There was no voluntary motion of the ankle-joint.

The knee-jerks were present, as well as the cremasteric and abdominal reflexes. There was no ankle-clonus. The three bed-sores had very much diminished in size and were covered with healthy granulation.

On Nov. 5, 1899, I received a letter from him, from Lancaster, Pa., in which he stated that his condition was very good. His bed-sores had entirely healed, the cystitis had almost disappeared, and, by means of two canes, he was able to get about. For the past three months he had been able to suport himself and his family, as a cigar-maker. He had full control of his bladder and rectum. He can flex and extend the knees and the toes.

Sick and Wounded in China.—Most complete arrangements have been made for the care of the sick and wounded in the Chinese campaign. Abundant medical stores, supplies, hospital tents and stoves have been provided. As, on account of the nature of the situation, a general hospital would be impracticable, a suitable field hospital will be established close to the field of active operations. Major-Surgeon John Van R. Hoff, U. S. A., will be placed in charge of this hospital. He is now on his way from Porto Rico to his new post of duty.

ANGINA PECTORIS.*

AUGUSTUS A. ESHNER, M.D.
Professor of Clinical Medicine in the Philadelphia Polyclinic, Etc.
PHILADELPHIA.

While the use of the Greek prefix "pseudo," or its English equivalent "false" in medical nomenclature is at times a matter of convenience, it may become a source of confusion or misunderstanding. This is exemplified in the use of the term "pseudo-angina pectoris."

Although the question of the pathology of angina pectoris is not definitely settled, it seems not unreasonable to attribute the symptoms of the affection to derangement in the function of the cardiac plexus of nerves, usually induced through interference with the circulation in the coronary arteries, or through disease of the myocardium.

In addition, however, to cases in which such vascular or myocardial disease is present, there are other cases in which similar symptoms arise, in the absence of appreciable organic disease referable to the heart. To this latter condition, the designation "pseudo-angina pectoris" has been applied, and among the etiologic factors, toxic and neurotic states have especially been mentioned. It seems more logical, however, to include both sets of cases in the same group, even though they differ in intensity, clinically, as well as pathologically, and it were, perhaps, better to distinguish them rather as mild and severe, than as false and true.

We have here an illustration of the difficulty of attempting a distinction between organic and so-called functional disease. It is difficult to conceive of derangement of function without alteration in structure. Functional activity must itself be looked upon as an expression of metabolic activity, and aberration of the former would accordingly bespeak deviation of the latter from the normal. Disorder of function may, therefore, be referred to influences varying in degree from impalpable nutritional disturbance to gross organic lesion. Between these extremes there may be all gradations. It can further be understood that long-continued or frequently repeated nutritional disturbance may lead to *structural and ultimately to organic disease.*

Of the several explanations that have been proposed for the occurrence of the symptoms of angina pectoris, viz.: That these are due to neuralgia of the cardiac nerves, spasm of the heart-muscle, stretching of the ventricular wall, and anemia of the myocardium, it is not impossible that each or even all have some share in their causation. In this way the paroxysm may be induced by organic disease, or by spasm of the coronary arteries, or of the muscular wall of the heart, acute dilatation and toxic states, singly or in association.

The essential features of angina pectoris are its paroxysmal occurrence, the presence of intense precordial pain and a sense of anguish and impending dissolution. Those who undertake to maintain a distinction between true and false angina pectoris, consider a fatal issue an additional feature; but in this connection it is worthy of mention that there may be grave disease of the coronary arteries and myocardium, even terminating fatally, without symptoms of angina pectoris, and, conversely, it does not seem extravagant to believe that angina pectoris may exist in the absence of gross or appreciable changes in the vessels or the heart-muscle. The element of death further, would hardly be a safe criterion, inasmuch as it can scarcely be attributed to the attack of angina pectoris itself, but is rather to be ascribed to the fundamental disease of the vessels or the heart-muscle, and it would occur only when this is present.

---

*Read before the Section on General Medicine of the College of Physicians of Philadelphia, May 14, 1900.

True, or severe, angina pectoris is said to occur principally after the fiftieth year of life. Of forty cases referred to by Osler in his admirable monograph, only four were under forty (one at thirty and one at thirty-two), the average age being fifty-three. He adds that cases are reported in young individuals, even in children; but then almost invariably in association with chronic valvular disease or adherent pericardium. The cases of mild, or so-called false, angina pectoris, it is admitted, may occur at any age, and even in early life.

Osler in his text-book tabulates as follows the points of differentiation between true angina and pseudo-angina.

TRUE ANGINA.	PSEUDO-ANGINA.
Most common between the ages of 40 and 50 years.	At every age, even 6 years.
Most common in men.	Most common in women.
Attacks brought on by exertion.	Attacks spontaneous.
Attacks rarely periodic or nocturnal.	Often periodic and nocturnal.
Not associated with other symptoms.	Associated with nervous symptoms.
Vasomotor form rare.	Vasomotor form common.
Agonizing pain and sensation of compression by a vise.	Pain less severe; sensation of distension.
Pain of short duration.	Pain lasts one or two hours.
Attitude: silence, immobility.	Agitation and activity.
Lesions: sclerosis of coronary artery.	Neuralgia of nerves and cardiac plexus.
Prognosis grave, often fatal.	Never fatal.
Arterial medication.	Antineuralgic medication.

These differences depend largely upon the character of the respective underlying pathologic processes, but herein does not seem to reside sufficient reason for separating the two groups of cases entirely. Neuralgia may be purely a neurosis, or it may result from nerve-lesions, traumatic and inflammatory, neoplastic, etc. A similar conception appears not inapplicable also to angina pectoris.

I beg to report a case that I believe to be one of true or severe angina pectoris occurring in a young man 30 years of age and unattended with organic disease of the heart or vessels.

G. G., aged 30, a nurse, was received into the Polyclinic Hospital on September 12, 1899, suffering from sharp, knife-like pain, extending from the heart to the left shoulder, and down the left arm. The attack had set in while the patient was riding in a street-car after a day of hard work. No physical abnormity whatever was detected, and pulse, respiration and temperature exhibited no noteworthy deviation from the normal. The family history was insignificant, except that the maternal grandfather had died from an apoplectic seizure. The patient himself had had scarlet fever, measles, and mumps, and was rather delicate as a child. I believe he was not addicted to the excessive use of tea, coffee, tobacco or alcohol. He had suffered from rheumatic pains and swelling in the knees and ankles for several successive springs. Two years previously, following an attack of rheumatism, he was seized with the first of a series of paroxysms like the present. The second attack occurred seven months later; and others had taken place at intervals of six months. Each attack had begun with a severe paroxysm, and was attended for twelve hours afterward with a number of lesser severity, followed by a period of collapse for about a week. The attacks usually came on after over-work or excitement. This history was essentially repeated while the patient was under observation in the hospital, several paroxysms occurring, though none so severe as the first. The treatment consisted in the administration of amyl nitrate in pearls by inhalation, hypodermic injection of morphin, the administration of nitroglycerin internally, and applications of heat and counter-irritation to the precordium. Subsequently strychnin and atropin were also given, and the patient was discharged after the lapse of ten days, quite restored to his usual condition.

As already stated, I have little doubt that this case is one of true angina pectoris, although no evidence of organic disease of the heart or the vessels could be made out. It is, however, not impossible that, as a result of the earlier attacks of rheumatism, insidious changes had been set up in the myocardium or the coronary arteries, to which the conditions present are to be attributed.

Therapeutics.

Treatment of Hay-Fever.

In his article on Hay-Fever, in the "Twentieth Century Practice of Medicine," Dr. E. F. Ingals speaks of the importance of observing the following things in the management and treatment: 1. The condition of the constitution predisposing to the attack, such as a rheumatic or gouty diathesis or disturbance of the stomach or bowels. 2. The neurotic tendency. 3. The hyperesthetic mucous membrane.

The constitutional treatment especially should precede the usual time of the attack at least one month or six weeks.

The following prescriptions are based on the outline given above:

℞. Liquoris potassii arsenitis..................ʒi 4|
Tinct. nucis vomicæ..........................ʒii 8|
Tinct. gentianæ compositæ, q. s. ad......℥iii 96|
M. Sig. One teaspoonful after each meal in water.

℞. Sodii arsenatis............................gr. i |06
Ext. nucis vomicæ......................gr. viiss |5
Ferri sulphatis.........................gr. xlv 3|
Sodii carbonatis.......................gr. xlv 3|
M. Ft. capsulæ No. xxx. Sig. One capsule after each meal three times a day.

℞. Quininæ hydrobromatis..............gr. xxx 2|
Sparteinæ sulphatis...................gr. viiss |5
Ext. hyoscyami..........................gr. x |66
Pulv. camphoræ........................gr. xxx 2|
M. Ft. capsulæ No. xxx. Sig. One capsule every four hours.

℞. Liquoris sodii arsenatis....................℥i 32|
Tinct. belladonnæ............................ʒi 4|
M. Sig. Five drops in water after meals, as a prophylactic measure.

℞. Zinci valerianatis........................gr. iii |18
Asafœtidæ ....ʒiss 6|
M. Ft. capsulæ No. xxiv. Sig. One capsule after each meal.

℞. Syrupi acidi hydriodici....................℥iii 96|
Sig. One teaspoonful after each meal three times a day.

This preparation is beneficial when there is a history of a rheumatic diathesis. If necessary this could be given alternately with some one of the above prescriptions.

℞. Liquoris potassii arsenitis.................ʒi 4|
Potassii iodidi ....ʒiss 6|
Vini pepsini, q. s. ad.......................℥iii 96|
M. Sig. One teaspoonful in water three times a day.

This combination is of value as a prophylactic measure and during the attack in rheumatic patients.

℞. Brucinæ phosphatis......................gr. iii |18
Ext. hyoscyami..............................gr. xv 1|
Quininæ valerianatis..........................ʒi 4|
Camphoræ ....gr. xxx 2|
M. Ft. capsulæ No. xxx. Sig. One capsule four times a day.

Dr. E. Fletcher Ingals recommends the above prescription, which in his experience has seemed the most beneficial in warding off the attacks. He also states that this combination is not only advantageous in delaying or preventing an attack, but it seems to be of much value in mitigating the patient's suffering during its progress.

Brucin, as is well known, is one of the alkaloids of nux vomica and, as compared with [illegible] is [illegible], slower in its action and twelve times [illegible]

℞. Ext. nucis vomicæ..... [illegible]
Ext. hyoscyami........ [illegible]
Salopheni .... [illegible]
M. Ft. capsulæ No. xxx. [illegible]
day.

Salophen is used a great deal as a substitute for salol in order to avoid the direct liberation of phenol in the intestinal tract, as salophen is split up in the intestine into salicylic acid and acetyl-p-amidophenol. It can be substituted for salol in cases with a rheumatic diathesis.

FOR RELIEF OF SUBJECTIVE SYMPTOMS.

The following prescriptions are for the purpose of relieving the subjective symptoms:

℞. Antipyrini ....ʒiii 12|
Syrupi aurantii corticis..................℥i 32|
Aquæ destil., q. s. ad..................℥iii 96|

M. Sig. One teaspoonful three times a day during the attack early in the disease.

℞. Pulveris morphinæ compositi.............ʒi 4|

Ft. capsulæ No. vi. Sig. One capsule as required for the relief of the dyspnea.

This powder contains morphin sulphate, 1 part, camphor, 19 parts, and licorice and calcium carbonate, 20 parts each, consequently ten grains of the powder contains 1/6 grain of morphin, hence the necessary precautions in its administration.

℞. Chloralis hydratis ....ʒii 8|
Elixiris *ammonii valerianatis*..........℥iii 96|

M. Sig. One teaspoonful in water every four or five hours to relieve the attacks of dyspnea.

℞. *Acidi boracici*.......................gr. xv 1|
Aquæ camphoræ, q. s. ad..................℥i 32|

M. Sig. To relieve the itching of the conjunctivæ, by local application.

Or,

℞. Sodii biboratis......................gr. viiss |5
Aquæ camphoræ............................℥i 32|

M. Sig. Bathe the eyes as often as necessary and drop one or two drops in the eye every three hours.

℞. Acidi boracici
Sodii bicarbonatis, āā.................ʒii 8|
Acidi carbolici......................gr. xxiv 1|5
Aquæ destil ....Oi 512|

M. Sig. Use as a spray locally, to thoroughly cleanse the mucous membranes of the nose and pharynx.

The necessity of keeping these membranes clean is the one point dwelt upon by those who have written at length on the treatment of this disease; preventing, as it does, the foreign irritants from coming in contact with the membranes.

℞. Quininæ muriatis....................gr. viiss |5
Aquæ destil..............................℥i 32|

M. Sig. Apply to the nares with a swab, three or four times a day.

℞. Adrenals (desiccated)...................ʒi 4|
Acidi borici..........................gr. xvi 1|
Aquæ cinnamomi.........................ʒiv 16|
Aquæ camphoræ (hot)......................℥i 32|
Aquæ destil. (hot), q. s. ad............℥ii 64|

M. Macerate for four hours, then filter. Sig. Use as a spray in the nares.

The value of this preparation has already been dwelt upon in a previous number of The Journal, but we find it necessary to speak of it again in this connection as being invaluable in treatment of hay-fever. When locally applied it produces marked and prompt contraction of the arterioles of the mucous surfaces.

℞. Tablets pulv. adrenals (desiccated) āā..gr. v |33

No. xxiv. Sig. One tablet four times a day, allowing it to dissolve in the mouth.

Solis-Cohen, a sufferer from hay-fever for twenty years, found great relief during an attack by *taking the preparation in this* way. It not only contracts the arterioles but acts as a tonic to the heart.

℞. Cocainæ hydrochloratis
Thymol, āā.........................gr. iii |18
Bismuthi subcarbonatis..................℥ii 64|
Vaselini ....℥i 32|

M. Sig. Apply locally to the nares once or twice a day with an applicator.

℞. Menthol..............................gr. vi |36
Bismuthi salicylatis
Sacchari lactis, āā..................gr. lxv 4|30

M. Sig. A small quantity to be insufflated into the nares two or three times a day.

℞. Thymol ....gr. 1/4 |015
Ol. caryophylli.........................m.ii |12
Cocainæ hydrochloratis.................gr. iii |18
Liquid albolene..........................℥i 32|

M. Sig. *To be used as a spray five or six times a day.*

This prescription must not be repeated by the druggist nor placed in the hands of the patient to be refilled at will.

℞. *Acidi boracici*....................gr. xxx 2|
Sodii salicyl...................gr. xxxviii 2|5
Cocainæ muriatis.......................gr. iss |09

M. Sig. To be insufflated into the nostrils.

This powder will generally give relief to the patient during the height of the attack, but it should be made up under the supervision of the physician, and it is *especially important* that no prescription be given to the patient for it. Not more than one-fourth of this powder should be used daily, and this *should not be long continued. Powders are most conveniently* applied by the patient himself, with a small glass tube about four inches in length and 1/8-inch in caliber, one end of which *has been slightly flattened, the other end being attached to a* rubber tube about ten inches long. Placing the required amount of powder in the round end, pass the rubber tube over *it, insert the flat end in the nares and blow quickly through the* tube.

℞. Orthoformi ....ʒiv 16|

Sig. To be used by insufflation three or four times a day.

Litchwitz reports good results from the use of this preparation.

Orthoform is a white tasteless powder, non-toxic, and is antiseptic and anesthetic when locally applied.

℞. Codeinæ ....gr. ss |03
Potassii bromidi.......................gr. x |66
Chloralis hydratis.....................gr x |66
Syrupi grindeliæ robustæ...............ʒii 8|

M. Sig. *At one dose, to be repeated in one hour unless re*lief is sooner obtained. —*Ingals.*

℞. Hydrozone ....℥i 32|
Aquæ destil............................℥xii 384|

M. Sig. Four times daily as a nasal douche, beginning two weeks previous to the usual time of the attack.

℞. Resorcini ....gr. x |66
Aquæ destil., q. s. ad..................℥ii 64|

M. Sig. Use as a spray two or three times a day.

—*Hare.*

Resorcin is obtained by fusing many resins with potash. It is a phenol and closely allied to carbolic acid, but is odorless, more soluble and non-irritant. It is said to be equally as powerful as carbolic acid as an antiseptic. It is neutral in action, and is generally prescribed in solutions of 2 per cent. strength when locally applied or in the form of a spray.

℞. Menthol ....gr. i |06
Acidi carbolici..........................m.i |06
Ol. gaultheriæ ....m.i |06
Liq. albolene, q. s. ad..................℥i 32|

M. Sig. Use as a spray three or four times a day.

In this prescription the ingredients can be used in somewhat greater strength if necessary. But in the use of sprays excessive irritation should be avoided, and if the mucous membranes smart for more than two or three minutes the strength of the oily sprays should be reduced, or in some cases entirely substituted by sprays of aqueous solutions.

Roe, of Rochester, reports remarkable success in curing hay-fever by cauterizing the hyperesthetic areas at different times.

Dietetic Treatment of Diabetes Mellitus.

In the treatment of diabetes mellitus Külz *recommends* the administration of a sufficient diet composed of albuminous and fatty food, and then to add to this, after trial in each case, such articles of carbohydrate *food, in definite amounts*, as the patient shows himself able to assimilate. The following is an example of the strict diet:

Breakfast at 8 *a.m.*—2 cups of *coffee*, yolk of egg, 2 tablespoonfuls of cream, 2 eggs, 150 grams (5 ounces) of ham, 50 grams of cheese, 10 grams of butter.

Second Breakfast—1 *cup of bouillon*, 2 *yolks of eggs*, 200 grams of roast beef, 30 grams of cheese, 10 grams of butter.

Dinner—1 cup of bouillon with yolk of egg, 100 grams of salmon, 15 grams of butter, 200 grams of sirloin, with 20 grams of butter sauce, spinach-salad with oil, 30 grams of curds with butter, 1 cup of coffee, 2 tablespoonfuls of cream, 1 cup of tea, 2 eggs.

To this 1 liter of wine and 30 grams of cognac are to be added.

Cacodylates in Chorea.

Garand has found rectal injections of sodium cacodylate extremely effective in rebellious cases of chorea. The dose was 5 c.c. of a .5 per 200 solution daily for five days, then twice in five days, and then three times, suspending for five days and recommencing. By the end of the month all the children were cured. There were no after-effects nor intolerance in the three cases. Luigi recommends salicylic medication by the skin in cases with rheumatic antecedents, supplementary to internal medication.

Medicolegal.

Experiments as Evidence.—The Supreme Court of Utah holds, in the case of Konold vs. the Rio Grande Western Railway Company, that experiments are not competent as evidence unless the conditions under which they are made are the same, or approximately the same, as those which attended the event in regard to which the experiments are made. And, the admissibility of such evidence being discretionary with the trial judge, his decision, it says, will not be reviewed, except in case of a palpable abuse of such discretion.

Board of Health Can Not Authorize Nuisance.—The third appellate division of the Supreme Court of New York says, in the case of Mann vs. Willey, that it can find no statute nor rule of law, which confers upon a board of health the right to authorize one citizen to create and maintain a nuisance to the injury of another. Here the defendant was seeking to justify the discharging of the sewage of a summer hotel into a stream by reason of an order of the board of health of the town in which the hotel was situated. Such board, the court says, may have had authority to prevent him from maintaining cesspools, but it could not have compelled him to sewer into the stream.

Worry as a Ground for Damages.—The rule is well established, says the second appellate division of the Supreme Court of New York, that when the injury to an intelligent being, caused either by wilfulness or by negligence, produces mental as well as bodily anguish and suffering, independently of any extraneous consideration or cause, it is imposible to exclude the mental suffering in estimating the extent of the personal injury for which compensation is to be awarded. And worry being an element of mental suffering, it holds, in the case of Webb vs. the Yonkers Railroad Company, that it is competent to show the worry over an injury where the mental suffering resulting therefrom is a proper element of damage.

Not Evidence of Injury to Married Woman.—In order to prove the internal injuries which she alleged that she had suffered through the defendant's negligence, the plaintiff, in the case of Sweeny vs. the Union Railway Company of New York City, called as a witness a physician who testified as to her physical condition on a date more than two years after the accident. In the meantime she had given birth to two children. The physician who had attended her found no internal injuries whatever. The one here called as a witness testified as to certain injuries to the genital organs, which were wholly unconnected, so far as the evidence showed, with the accident two years before, but which might naturally have resulted from one or the other of the two intervening confinements. Such evidence, the appellate term of the Supreme Court of New York holds, had no place in the case, and it was error to admit it over the defendant's objection.

Validity of Release of Claims for Injuries.—The Supreme Court of Kansas holds that if a passenger who is negligently injured in a railroad wreck is at once treated by a physician of the railroad company, and hours after the injury, and while nervous, weak and sick, is again visited by the physician and the claim agent of the company, and, by false and fraudulent representations of the physician that his injuries are slight and temporary, is induced to execute a release of all claims for damages for a trifling amount, he will not be bound by such release. On the other hand, if the release is fairly obtained and understandingly executed, it will, the court holds, in Missouri Pacific Railway Company vs. Goodholm, constitute an effectual bar to a recovery for the injuries. To sustain a claim that the execution of such a release was induced by false and fraudulent representations, it must appear that the party who executed it relied and acted upon such representations.

Selection of Members of Boards of Health.—From an examination of the history of the legislation in the state of New York in relation to appointments of boards of health in cities, the special term of the Supreme Court of New York, Albany County, says, in re City of Rensselaer, that it seems clear that the legislature still intended by its latest statute to make the selection of the members of the boards of health the joint action of the mayor and the common council; the mayor to nominate, and the common council, in its discretion, to appoint or confirm his nomination. If the common council does not confirm or appoint the men nominated by the mayor, it goes on to say, it would seem to be the mayor's duty, in his discretion, to send in other names, and to continue sending such names until an appointee is named who will be appointed by the common council. Hence, it here denies a peremptory writ of mandamus to compel the common council and aldermen of the above city to convene and forthwith appoint the mayor's nominees as commissioners of health of said city.

Cuts Down Allowance for Injury to Knees.—A school teacher, 39 years of age, was thrown from her seat and quite severely injured by the sudden stopping of a street car on which she was a passenger; the injury sustained being a dislocation of the internal semilunar cartilage of each knee, with other injuries to her body. Commenting on her case, there is no question, says the first appellate division of the Supreme Court of New York, that her injuries were severe, and that she suffered much pain; that the effect of the injury continued over more than eighteen months up to the time of the trial, and to some extent interfered with her work, and was a constant annoyance to her; that she will never entirely recover from the injury, and will always experience more or less weakness of the knees, and difficulty in walking. But an award of $15,000 for such injuries, it holds, Kraemer vs. Metropolitan Street Railway Company, is certainly quite excessive. It maintains that $7000, in addition to the actual outlay or liability incurred by the plaintiff, would be full compensation for the injuries sustained; wherefore, it has ordered a new trial, unless the plaintiff stipulates to reduce the judgment accordingly, which would make the total amount thereof $8,836.30, instead of $15,000.

Constitutionality of Pure-Food Laws.—The Supreme Court of Ohio holds, in State vs. Capital City Dairy Company, that it is within the scope of the police power of the state to regulate the manufacture and sale of articles of food, even though the right to manufacture and sell such articles is a natural right guaranteed by the constitution. Especially does it here hold that the police power of the state is properly exercised in the prevention of deception in the sale of dairy products, holding valid a number of Ohio statutes passed for that purpose and to preserve the public health, as it is stated. And, in this connection, it particularly affirms that where the article sought to be regulated may easily be manufactured so as to be harmful, and thus result in fraud upon and injury to the public, the police power is properly exercised in the regulation of the manufacture and sale of such article by such requirements as will tend to insure the public against fraud and injury. Nor does it consider that there is any question whatever in regard to the power of the state to compel a sample for analysis of any article of food. Besides all of which, it is of practical interest, in this day of corporations, to note that it is here further held that the mere fact that the criminal laws of the state provide for the punishment, by fine, of those who offend against these pure-food laws is not a bar to a proceeding to oust a corporation engaged in violating them from the exercise of its right to be a corporation.

FATAL OIL EMBOLISM FROM SUBCUTANEOUS INJECTION OF OLIVE-OIL—LEUBE'S METHOD.

It is known that a moderate degree of fat embolism takes place commonly after various injuries, especially fractures, and also in connection with such diseases as puerperal eclampsia. In the majority of cases this form of fat embolism is of no special significance, the fat being removed by phagocytes and absorbed in case life is present. Occasionally, however, severe injuries accompanied with much contusion and fractures give rise to such a degree of fat embolism that it becomes a direct cause of death. Experimentally, it has been found that subcutaneous injections of olive-oil may lead to fat emboli in the lungs, either by way of the lymph-vessels and the thoracic duct or perhaps on account of the puncture of a small vein. Möller has reported severe pulmonary symptoms after subcutaneous injection of mercury rubbed up with oil, and caused by perivascular pneumonic areas about minute emboli of mercury. On account of the small quantity injected—1 to 3 or 4 grams—the oil, even when inserted intravenously, probably would produce only small hemorrhagic infarcts without recognizable symptoms.

In Leube's method of subcutaneous nourishment with daily injections of olive-oil, as much as 50 to 200 c.c. are introduced at one time. Though used extensively and with good results by several authors, no evil effects from oil embolism appear to have been observed until the recent report by Fibiger[1] of death from the accidental intravenous introduction of olive-oil during its subcutaneous injection in a patient with stricture of the esophagus. Attempts at nourishing the man through the mouth and by enemas failed completely, and death from inanition seemed imminent. Daily subcutaneous injection of sterile olive-oil in doses of 150 c.c. produced marked and progressive improvement; after 19 days, when 2325 c.c. oil had been injected, a gain in weight of 4600 grams had taken place. On the twentieth day the injection was followed by the violent cerebral and respiratory symptoms characteristic of fat embolism, and death took place on the third day. There was observed a transitory, left, incomplete hemiplegia.

The post-mortem showed collections of oil in the subcutaneous tissue; the puncture from the last injection ended in a hemorrhagic infiltration about a small vein. Emboli of oil were found in practically all organs, most numerously in the lungs and in the brain. The left hemiplegia was produced by a large number of emboli in the right, cortical, motor centers. Small areas of bronchopneumonia and a serohemorrhagic exudate were found in the lungs, presumably to some extent caused by the streptococci present. In the kidney the oil had accumulated in the glomeruli. There were numerous oil droplets in the cells and in the lumens of the convoluted tubules of the second order; the urine contained fat. This fat is regarded as the result of fatty changes in the epithelial cells of the tubules, due to the anemia from the plugging of the glomerular capillaries.

Leube's subcutaneous nutritive oil injection, while a very efficacious method, consequently brings with it the danger of fatal oil embolism from the accidental puncture of small veins.

NON-DIABETIC GLYCOSURIA.

Although the exact mechanism of the development of glycosuria is not known, it has become perfectly well recognized that the manifestation is merely a symptom that may be associated with any one of a number of conditions. It has perhaps been longest and best known as one of the phenomena of diabetes mellitus, and too commonly the two have been considered identical. Whether or not there may be a grave diabetes without glycosuria, as there may be a marked glycosuria without diabetes, is a question for future investigation to decide. Perhaps, too, there is a more intimate relation between diabetes mellitus and diabetes insipidus than is generally acknowledged Sugar is not found in the urine with great frequency under ordinary conditions, either in disease or in health, although in some persons it may readily appear upon excessive indulgence in saccharine or amylaceous articles of food. Saundby[1] recently in a lecture considered several varieties of non-diabetic glycosuria, and cited illustrative cases. He pointed out that even in health the urine contains traces of sugar, but in amounts so small as to be beyond detection with ordinary tests. The most available test for glucose is Fehling's solution, the use of which is attended, however, with the liability of error from the presence of other copper-reducing substances, but these can be removed by repeated filtration through animal charcoal. No reaction should be considered positive unless the reduced copper appears as an orange-red precipitate. Even in health there is a limit to the power of the organism to assimilate sugar. This will naturally vary in different individuals, but for the present it has been placed at 100 or 150 grams of glucose—Saundby makes it between 300 and 500 grams of syrup of glucose. Glycosuria resulting from the ingestion of glucose in excess of the amounts indicated has been designated alimentary or physiologic, and is not considered of itself to be of evil prognostic omen, or as likely to terminate in diabetes. Saundby, however, records cases in which glucose appeared in the urine for long periods of time after the ingestion of ordinary amounts of carbohydrates, although other symptoms of diabetes were not present.

---

[1] Nordiskt Medicinskt Arkiv, 1900, xi, Häft 1.

[1] British Med. Jour., April 14, 1900.

Alcohol may cause glycosuria, which may be intermittent or constant, in accordance with the operation of the etiologic factor. Disease of the liver in association with, or independent of, alcoholism, also at times gives rise to glycosuria. Diseases of the stomach may act in the same way. Saundby expresses the opinion that the last three varieties of glycosuria may have some connecting link, which, could it be discovered, might throw some light upon the true etiology of the disorder. It is thought probable that this factor consists in some derangement of one of the important organs concerned in digestion, and from the relation of the liver to sugar-production, it is not unreasonable to regard this organ as the one most likely to be at fault. It may be that, under such conditions, sudden discharges of sugar take place from the liver into the blood in quantities greater than can be used up in the body. Glycosuria occurs, further, in cases of neurasthenia, without other discoverable cause. Saundby refers, finally, to glycosuria in old persons suffering from senile decay, and unattended with other symptoms of diabetes. The appearance of sugar in the urine, under these circumstances, must be looked upon as an indication of the general tendency to break down, and the diet should not be too rigidly restricted.

In addition to the foregoing, glycosuria may result from various disturbances of the nervous system—from functional disorders to organic disease—from toxic and infectious causes, from pancreatic disease, and probably from other influences.

THE NECESSITY FOR THE ISOLATION OF CASES OF TUBERCULOSIS IN HOSPITALS.

In conformity with the guiding principles of modern hygienic requirements the two most important indications in the management of all infectious diseases are isolation and disinfection. While there is no marked dissent from this general proposition, occasionally objection is raised to its universal, and particularly its rigid, application. This is especially the case with regard to tuberculosis, in the repression of which great activity has recently been exhibited in various ways and in many places. The question as to whether isolation of tuberculous patients in hospitals is necessary is answered virtually in the negative in a recent communication by Aron[1], who points out that in justification of the demands for the erection of special hospitals and special departments for tuberculous patients attention is generally directed to the dangers to which those surrounding such individuals are exposed. Long before its cause had been discovered, tuberculosis was known to be a communicable disease, but according to those who advocate the isolation of its victims, these should be separated from other patients in the hospital who may readily become infected on account of the infectivity of the disease. This principle has, however, not been applied generally to other infectious diseases, and it is thought probably never will be rigidly applied. As from 10 to 20 per cent. of the patients in the wards of many hospitals have been tuberculous, it might be assumed that in the many years of such association the percentage of infections that could with certainty be traced to this source would be quite considerable if tuberculosis were actually as infective as has been contended by some.

As a matter of fact, the number of cases of well-authenticated house-infection reported is small. Investigation into this subject is necessarily attended with great difficulty, as the incubation-period of tuberculosis sometimes is probably exceedingly long, and the disease might develop only a long time after the patient had left the hospital. In view of the wide distribution of the disease, and the many opportunities for infection, it is not easy to decide whether a given case has originated in the hospital or elsewhere. Even in cases of apparent house-infection it is not impossible that the tuberculosis was already latent, and became excited into activity only by some other infectious disease.

Instances of hospital-infection are not so rare in physicians and nurses, but here the relations with the sick are in various ways far more intimate, and the risk of infection is naturally much greater. Even these dangers are, however, largely to be avoided by the exercise of care and cleanliness. If the tuberculous patient were so dangerous to others he would be not less so for himself, and the likelihood of recovery would be much less than there is reason to believe it to be. It is argued that if it is possible by means of suitable prophylactic measures to reduce to a minimum the risks from tuberculosis, there would be no necessity for separate establishments for such cases. Then, it is pointed out, an evil moral effect would be exerted by the association of tuberculous patients exclusively. It will thus be seen that, while there is a strong consensus, there is wanting unanimity, of opinion in favor of the segregation of tuberculous patients.

BRITISH MEDICAL SERVICE IN THE TRANSVAAL.

The ball started by Mr. Burdett-Coutts, when he charged medical mismanagement of the South African war, as might be expected, continues to roll. It is so easy to find defects, and hardships are so common in war time that philanthropic posers can readily find pretexts for airing their virtue. In this war, which is unlike recent British wars in other respects than its magnitude, there is probably also the element of the complaining volunteer whose grumblings take the form of home letters and communications to the press. There is ample material therefore [illegible] sati[illegible] dictments, and here they seem [illegible] sc[illegible] medical department. In the [illegible] nothing was too good to say; now it seems that there is nothing that is too bad, in some quarters at least. Accusations, not only of inefficiency and neglect, but also of actual cruelty, have been made and the British public is naturally stirred.

---

[1] Berliner Klin. Woch., 1900, No. 21, p. 463.

A civil surgeon correspondent of the *British Medical Journal* who, as he says, "holds no brief for the Army Medical Service," reviews in its issue of July 28 these charges and complaints. Of course vague generalities can not be dealt with, but specific charges can be met. He shows that the faults, so far as they are real and definitely stated, can be accounted for by necessarily improvised conditions, and to some extent, as in our late war, by the failure of non-medical officers to duly co-operate with the medical staff. In Bloemfontein there was for a time a scarcity of beds and of some supplies, but this was due to the demand exceeding the transportation resources and was not the fault of the medical staff. The same is true of the deficiencies in some of the field hospitals. The charges against the depot hospitals, so far as they were true, are met in detail and shown to be due to unavoidable conditions. Some are contradicted from his own knowledge. The fact is, as he says, that if perfect attendance of the sick and wounded, even at the base, is to be a *sine qua non*, "the British taxpayer must keep a permanently trained medical staff of at least six times the present number for a national emergency that may never occur again," and that as for perfection at the fighting front, no money and no organization will secure it.

Any one who has had any practical experience of the hurly-burly of active war will appreciate the justice of this last remark. War is not a picnic, and the sick and wounded are not in a situation to secure home comforts, at the best. Many a veteran of our civil war can tell of conditions that far exceeded anything in the Transvaal, or even in our late war with Spain, where the situation in Cuba was necessarily far worse than in the comparatively healthy South African region. So far as the British medical staff is concerned we believe that it has done all that its resources would permit.

THE CAPE NOME SITUATION.

The reports from Cape Nome, Alaska, do not indicate a very satisfactory sanitary condition at that point. The rush of 20,000 or more reckless gold-seekers into a region as little fitted probably for such an increase of population as can be found has raised some serious sanitary problems for the local officials and physicians. The country, excepting on the hill slopes, is a saturated sponge of moss wherever the frost has left, and, though pools and streams exist, good water is nevertheless scarce. It is easy to see what unsanitary conditions may arise under such circumstances; typhoid, intestinal disorders, etc., are very likely to be prevalent and serious epidemics are a possibility. As the season advances and the supply route by sea is closed, the food question becomes a factor, and dietetic disorders such as scurvy are likely to prevail. At all times the rheumatic virus, whatever it may be, is to be considered, and many who have never had such troubles will date them from their Alaskan experience. The most hopeful feature of the situation as reported is that the military authorities have taken hold actively and that there is therefore prospect of some sort of a local government. Without this, the outlook would certainly be bad, not merely for the present but also for the future.

ADVERTISING QUACKS AND MALPRACTICE SUITS.

A French author[1] calls attention to the serious results that sometimes follow self-treatment with quack-remedies advertised in the daily press. As a gynecologist he had occasion to observe several instances of this kind of malpractice. In one typical case a patient suffering from an incipient cancerous growth which had before been successfully removed objected to a new operation, on a slight recurrence, and had recourse to an advertised electric treatment. The result was rapid stimulation of the growth, which soon became a vast inoperable mass, and death. He suggests that the only remedy for such occurrences is to have suits instituted promptly against the advertisers of such nostrums and appliances when their disastrous effects have been experienced. Exemplary damages would soon teach quacks a lesson, their publicity would enlighten the public, and even if not fully successful their effects would still be beneficial. The law thus applied would be the best medicine for this social disease of advertising quackery. The trouble is, the victims would dislike to have recourse to such a remedy; it is easier for them to swallow the injury and save their pride than to admit that they have made fools of themselves. The *amour propre* of the average dupe is the salvation of the quacks.

THE INCREASED PREDISPOSITION TO CANCER.

In a recent number of the *London Polyclinic* occurs a critique on diet as a cause of cancer. It is claimed that the increase in cancer is real, in the main, and not wholly due to increased accuracy in diagnosis. In reference to the theory that the disease is the result of overeating, it is admitted that there has been during the last 50 years a great increase in the amount and variety of food consumed by civilized people, and particularly that the working-classes now get vastly more meat than formerly. But cancer prevails more extensively, relatively, in the upper classes, and the consumption of tea and tobacco has increased much faster than that of meats, so that conclusions can not be safely drawn from such figures. The marked immunity of the negro race is pointed out as very inconclusive, as all accurate observers agree that the negro is an enormous eater both in Africa and in America. The testimony from India is indecisive, some holding that there is more cancer there than in Europe, and others that there is less, but all agree that it affects alike the rice-eaters and the meat-eaters, and that too in a country where food tends always to be meager and where famine frequently prevails. The conclusion drawn from a survey of the field seems very reasonable that "increased consumption of food may possibly be a predisposing cause of cancer, in so far as it promotes survival to the cancer age, but that otherwise its relation to the increase of the disease has not yet been shown to be probable."

---

[1] Folet: L'Echo Méd., July 15.

THE EPIDEMIOLOGY OF MALARIA.

Existing evidence leaves no room for doubt that malarial fever is conveyed by mosquitoes; but it is not impossible that, in accordance with earlier conceptions, the disease may likewise be transmitted not only by air, but also by water. Demonstration of the one mode of infection does not necessarily preclude the possibility of the others. The matter is one not solely of scientific interest, but it has a most important prophylactic bearing, inasmuch as we can not hope to prevent the disease unless we appreciate all of the sources whence it may be derived, and take the necessary steps for their suppression. From a study of the sanitary reports of two army corps garrisoned in eastern provinces of Prussia, between the years 1884 and 1888, Grawitz[1] found that the largest number of cases of malaria were observed not in the late summer and autumn, as is generally believed, but in the months of May, June and July, the number rapidly increasing up to, and as rapidly declining after, the period mentioned. This period of greatest prevalence of malaria does not, however, correspond with the period of greatest activity of mosquitoes. Further, there has been a marked decline in the number of cases of malaria among the soldiers in the Prussian army in recent years, and this has been found to correspond with the regulation of drainage, proper construction of barracks, and provision of a pure water-supply. Organisms have been found in aquatic animals resembling malarial parasites, so that it seems at least not impossible that as the malarial parasite is the intermediate aerial host, so some animal living in the water may play an analogous rôle.

A MISTAKE IN OHIO.

The news comes from Ohio that the State Board of Medical Registration and Examination has taken such action recently as to practically nullify that section of the excellent new law of the State which provides a certain minimum standard of preliminary education to be attained by those desiring to enter upon the study of medicine. A high-school diploma granted after four years of study, or its equivalent, is the minimum requirement as fixed by the statute. But, in making up its list of subjects for the first examination of prospective medical students, the Board has cut out nearly two-thirds of the studies embraced in a high-school course, and has included many branches whose completion is required of those who wish to *enter* a high school. The profession of the State is stirred up over the matter, and while nothing can now be done toward changing the requirement for the autumn examinations, it is hoped that the Board in the future will either execute the law in accordance with its plainly expressed terms, or give way to another that will. It is rumored, we hope without foundation, that it was the influence of some of the weaker medical schools, which, by reason of their probably well-founded fear of loss of students, determined the Board in its illegal reduction of the educational standard. In this connection it is also to be remembered that the Ohio Board consists of seven members, only three of whom can be regular physicians, so that the hope may be permitted, in the absence of direct information, that these three were outvoted in this matter. In any event, we trust that, in the interests of the public welfare and of medical education, the Ohio Board will see the mistake it has made, and at the earliest possible moment retrace its steps to the secure foundation of enforcing the law in accordance with its explicit provisions.

A LAWYER DISBARRED.

Recently a lawyer of Chicago misappropriated—that is, appropriated to himself—twenty-seven dollars belonging to a client. For this he was sentenced to pay a fine and was "forever disbarred from practicing in the courts of Illinois." No one seems to have found fault with the verdict; the newspapers endorsed the judge, who, in rendering the verdict, said that the legal profession must be purged of those who would stoop to such dishonest and despicable acts. Neither have we any fault to find, for while it seems rather severe to take from this lawyer the right to practice his profession, his means of making a living, we can only say that he deserved the punishment. But in the newspapers which published the account of this disbarment, with approval, appeared advertisements of quack doctors. In some of these advertisements those suffering from incurable diseases are promised restoration to health; in others, old men whose eyes are growing dim with senile cataract are guaranteed perfect sight by means of internal medicines. The fears of indiscreet youths—who think they are ill but are not—are preyed on by these barnacles on the medical profession, the advertising quacks. This Chicago lawyer who was turned out of his profession for stealing twenty-seven dollars, is an angel compared to some of these. He only swindled his client out of a few paltry dollars; they not only do this but do so by preying on the afflicted, whose confidence they have obtained by false promises and by false pretences. These men write M.D. after their names; they claim to belong to a profession which certainly should be purified of its vicious adherents as much as should the legal profession. And yet, imagine the hue and cry that would be raised by the newspapers if the medical profession should attempt to purge itself of those who are using it as a cloak for dishonest acts and for swindling.

THE DIETETIC DIFFERENCES BETWEEN LIGHT AND DARK MEAT.

It has long been the custom under certain morbid conditions to exclude meat from the diet on the supposition that the products of its catabolism exert an irritating effect more particularly on the kidneys, and proscription has been made to apply especially to red meat. Among these contraindicating conditions are the uric-acid diathesis, epilepsy, and chronic nephritis. It has been thought that red meat contains more extractives and ptomaines than white meat, of which the former are especialy injurious to the kidneys. More recently, however, it has been contended that, chemically at least, there is really little difference between red meat and white meat, with the implication that, dietetically, the one is not more injurious in its effects than the other. For the purpose of removing some of the doubt in which this subject seems involved, Pabst[1] undertook a series of experimental observations upon the influence of various diets on the amount of urine eliminated and its specific gravity, the amount of albumin present, the presence of tube-casts, and on the general condition of the patient in cases of nephritis. Two patients were studied. They were permitted to have white meat for one week, a milk diet for the second week, red meat for the third week, a milk diet for the fourth week, and equal parts of light and dark meat for the fifth week. Urinary examinations were made daily. Little difference in the results was found as between light and dark meat, and likewise between these and a milk diet. These observations of themselves are, of course, too few on which to base a final opinion, but, taken together with other evidence, they go to support the view that the effects of dark meat are, perhaps, not so baneful as we have been accustomed to believe.

---

[1] Berlin. Klin. Wochenschrift, 1900, No. 24, p. 521.

SOME THEORETIC CONSIDERATIONS ON THE TREATMENT OF GONORRHEA.

Gonorrhea may be fraught with such serious danger that any suggestion looking to its more intelligent and more successful treatment should receive serious consideration. Some reflections of an interesting character in this connection are entered on by Jooss,[2] who points out that it is impossible to destroy from without gonococci that have gained entrance into the tissues, without at the same time injuring the latter. Nor can it be conceived that the remedies used will have the desired effect, as they must diffuse through the membrane in order to reach the micro-organisms. Only the uppermost layers of epithelium are not flushed by the fluids of the body, and they will, therefore, be indifferent in their reactions to chemical solutions. Active absorption from the urethral mucous membrane does not take place. Then, even if the gonococci were destroyed, it is possible that the disease might continue, in part through the actions of toxins, causing paralysis of the muscular coat of the vessels. It would seem, then, that it is against the latter that treatment should be directed. Astringents may be employed, but the results are not always permanent, the discharge often returning as soon as the injections are discontinued. This is due to the fact that the agent can act only on the surface and is unable to influence the deeper layers of the mucosa and submucosa. Experience would seem to indicate that the distending and stretching exerted by injections on the urethra, rather than the astringent or disinfecting qualities of the agent used, has an important influence in the cure of gonorrhéa. Gonorrhea can be considered cured when the tissues and the circulation are restored to the normal; when distension of the urethra is not followed by turbidity of the first portion of urine passed; when the prostate gland is soft and elastic, and not enlarged, and its secretion is not yellow; when discharge has wholly disappeared and the urethra is dry, and when both portions of the urine are clear.

DIPHTHERITIC PARALYSIS AND ANTITOXIN.

The question whether diphtheritic paralysis is more frequent now than before diphtheria antitoxin came into use would be a difficult one to answer. Ransom[1], in an experimental study of the relation of antitoxin to this troublesome sequel of diphtheria, suggests that the increased rate of recovery under the antitoxin treatment might appear to increase the frequency of paralysis. Under these circumstances it even might appear that the antitoxin actually produced the paralysis, directly or indirectly. Fortunately, guinea-pigs are liable to typical post-diphtheritic paralysis, and hence Ransom was able to investigate the problem indicated in a highly satisfactory manner, at least as far as this animal is concerned. Ransom found from his carefully devised experiments that in guinea-pigs paralysis may be expected with certainty after intoxication with not less than one-fourth of the minimal fatal dose; below one-eighth of this dose no paralysis was noticed. The larger the dose the more severe the paralysis, if the animal survives long enough. "Neutralized mixtures of toxin and antitoxin, containing only about one lethal dose or less, do not appear to cause paralysis." Antitoxin injected fifteen to twenty-two hours after quantities of toxin not greater than a fatal dose "exercises in larger doses a mollifying influence on the subsequent paralysis." With smaller doses of toxin this effect is more evident, but small doses of antitoxin have no distinct preventive effect. Applying these results to human beings, it is probably correct to infer that large doses of antitoxin early in the disease would have a favorable influence upon subsequent paralysis, especially cardiac. Ransom believes, however, that severe cases are likely to be followed by some paralysis in spite of even large injections of antitoxin. At all events it is entirely unlikely that antitoxin in any way favors the production of paralysis; on the contrary, it has a decided preventive action. It must also be remembered that, as already hinted, antitoxin prevents a fatal termination in many cases which might otherwise result in death, and it is in this class that paralysis is also likely to appear. In these we would have paralysis resulting oftener since antitoxin came into use, for the reason that more cases recovered from diphtheria.

ETHICS OF PROFESSIONAL SECRETS.

In a recent address the president of one of the branches of the British Medical Association[2] discusses the question of medical secrecy, with special reference to the duty of the physician. In some countries, notably in France, and in some of our states, all facts learned professionally are legally incommunicable. This certainly simplifies the legal point of view, but it does not improve the situation in some of its moral aspects. The author of the address referred to prefers the uncertainties of the English law, the judge settling each case according to its merits, leaving the law of slander or libel to deal with cases where actual wrong has been done. This may have its inconveniences, it is true, as a jury may be carried away by its sympathies or misled by clever advocates, but it certainly does leave a larger margin for conduct where questions of moral right are concerned. According to the French and the New York laws, the physician can reveal no confidences of his patients even to protect individuals or the public; he must even see an innocent man hanged without opening his mouth when his testimony might save him. That the courts would enforce the law to this extent in every case is perhaps doubtful, but it is in their power apparently so to do. The theory that a man's disease is in all cases a secret belonging to himself is wholly opposed to public policy, and if carried out to its legal sequence would make life insecure. The law directly opposes it in the case of certain contagious diseases that the physician is compelled to make public, and there are others that he might well think it equally his moral duty to report under special circumstances. With modern knowledge and theories regarding venereal disease, silence would be, under certain circumstances easily imagined, an unpardonable sin, and yet the French courts have awarded heavy damages for revelations under such conditions. If such is to be the law, that one can not warn even those nearest and dearest to him against contagion of the most loathsome and dangerous kind, then it ought to be made the duty of the medical profession to excite universal suspicion of such contagion, so that parents would demand that a thorough physical and other examination be made and the results reported before the marriage of their daughter is allowed. The marriage of a syphilitic, or a gonorrhea-infected man, to an innocent woman is a crime—in Michigan it is a statutory one—and medical secrecy ought not to stand in the way of its prevention any more than of any other criminal act. We would not let down the bars of medical ethics in this matter in the slightest, but we ought not to have our liberty to act according to the higher dictates of morals restricted by law. The French law in this respect and also that of New York appear to have gone too far in their comprehensive proscription of all medical revelations of facts professionally obtained.

Medical News.

WILLIAM B. BERRY, M.D., Speaker of the House of Assembly of the Cape of Good Hope, has been created a Knight of Great Britain and Ireland.

NAVAL MEDICAL SUPPLIES and dressings have been sent on the water-ship *Arethusa* to the American ships at Taku, China, by Surgeon-General Van Reypen of the navy.

DR. A. M. RUFFER, president of the Sanitary Maritime and Quarantine Board of Egypt, has received from the Sultan of Turkey the Order and Insignia of the Medjidieh of the second class.

A LUPUS INSTITUTE, modeled on Finsen's Phototherapeutic Institute in Denmark, has been founded at St. Petersburg. Dr. Sarapin, who has been studying under Finsen, has been placed in charge.

THE DEGREE of Doctor of Laws has been conferred by the University of Michigan and Dickinson College upon Dr. Lewis Stephen Pilcher, of the Methodist Episcopal Hospital, of Brooklyn, and editor of *The Annals of Surgery.*

THE ENGLISH-EGYPTIAN government has commissioned Professor Kolle, of the Berlin Institute of Infectious Diseases, to study the cattle plague and suggest appropriate measures against it, in a three months' trip to the Soudan.

THE RETIREMENT of Professor Potain of Paris, which is anounced, is of more than local interest, as his friends and well-wishers encircle the globe. In France the age limit for a hospital surgeon is 62; for a hospital physician, 65, except in case of professors of clinics, when the limit is extended to 70, and in case of a member of the Institute to 75, which is Potain's present age. His last lecture was on his favorite subject, the heart and lungs, and emphasized the remarkable harmony between the results of radiography and stethoscopy.

THERE IS MONEY IN IT.—It is stated that there are twice as many persons in the so-called schools of mental healing, faith-cure, "christian science," and the like, as there in all of the medical schools of the country. This is certainly encouraging.

DR. ALBERT EDWARD GUELPH.—The Prince of Wales has just been elected an honorary member of the British Medical Association. As he has received two medical degrees during the last year or two, and now is a member of the largest medical association in the world he is certainly to be congratulated.

PLAGUE IN LONDON.—A cablegram received from Passed-Assistant Surgeon A. R. Thomas, who is detailed for duty at the United States Consulate-General London, England, reports under date of August 3, four cases and two deaths from plague at London. Diagnosis was confirmed by bacteriologic examination. The cases were on the steamship *Rome.*

PENNSYLVANIA.

ABOUT three weeks ago diphtheria attacked a family by the name of Anstine, living in York, and out of the four persons affected three have died from the disease. The only survivor is a child 3 years of age.

THE WILLIAMSPORT HOSPITAL will at an early date be adequately equipped with a comfortable nurses' home, the gift of Mrs. Ida McCormick. The building will be three stories in height and 70 feet in length.

THE NATIONAL GUARD of Pennsylvania has gone into camp at Mount Gretna, where it will remain for some time. The medical department has recently been fitted out with surgical instruments and medical chests prepared by order of Surgeon-General Shoemaker. Troops to the number of 10.500 will be in attendance.

REPORT OF MEDICAL EXAMINATION.

The State Medical Examining Board announces that there were 330 applicants who took the recent [illegible] tion [illegible] sylvania, and of this number 42 fail[illegible] 13 One applicant was expelled for a[illegible] Th[illegible] attained, 92.36 per cent., was [illegible] Bertelot, of Philadelphia.

Dr. Wallace W. Dill, of Norristown, assumed, on August 1, the duties of resident physician at the Pottsdown Hospital. He succeeds Dr. J. A. Blackford.

Philadelphia.

Dr. E. J. Haines has been appointed resident physician at the Samaritan Hospital, in place of Dr. Ernest B. Mongel, resigned.

The number of deaths which occurred in the city for the week ended August 4, was 439, a decrease of 75 from the preceding week. The principal causes of death were: tuberculosis, 43; nervous diseases, 29; nephritis, 27; and heart diseases, 25.

During the past week 303 inquests were held by the coroner of this city. Of this number 35 were victims of the heat. Suicide follows next, with 21 deaths attributed to that cause. Drownings furnished 20 deaths; fireworks 20 deaths. The sum of $141.75 was paid out during this period for witness fees.

Dr. Robert G. LeConte has been elected surgeon to the Pennsylvania Hospital to succeed Dr. John Ashhurst, Jr., recently deceased. Dr. LeConte served as resident physician to the hospital from 1888 till 1890, and is also surgeon to the Children's and Bryn Mawr Hospital. He is now on his way to attend the International Medical Congress in Paris.

Dr. Benjamin Shoemaker, president of the Board of Managers of the Pennsylvania Hospital, has received a letter from Dr. Joseph Leidy, who is now attending the International Medical Congress in Paris, stating that the international jury at Paris has conferred a gold medal upon the management of the Pennsylvania Hospital for the services it has rendered humanity during the past century. The jury consisted of a representative each from Germany, Russia, Italy, Switzerland, Belgium, Spain, Hungary, England, France, and the United States.

A few days ago one of the daily papers called attention to one of the worst sources of pollution of the Schuylkill River yet discovered. The site was located at the Hunter farm below the city of Reading. An inspection was immediately ordered by the secretary of the Board of Health, Dr. Benjamin Lee, who found the report true and promptly ordered the nuisance (cesspool) abated. Out of the $6000 set aside annually for the use of the Board of Health only a small portion goes toward the abatement of nuisances of this kind.

MARYLAND.

Dr. C. P. Carrico, the physician at the Maryland House of Correction, has found forty-seven cases of scurvy there, resulting from improper diet. The cases are improving under an increased supply of vegetables.

Baltimore.

The Johns Hopkins Chemical Laboratory Building has been completed, and it only remains to install in it the apparatus. The building was destroyed by fire last December.

Since January 1, the city has collected on account of insane patients treated at various institutions $2964.72. By the end of the year the amount is expected to reach $5000.

Dr. Llewellyn Elliott, of the Washington (D. C.) Health Department, was in Baltimore, August 3, studying the health department's method of treating smallpox and varioloid outbreaks.

Dr. William B. Burch has resigned his position as one of the police surgeons, the salary of which is $1000. The reason assigned is that he is dissatisfied with the rule established by the board of police examiners requiring the physical examination of candidates to precede the mental examination.

"Dr. C. A. von Ahlefeldt," who represented himself as a surgeon in the German navy, and left Baltimore after imposing upon the Johns Hopkins Hospital staff, and running up a bill at the Stafford Hotel, was arrested at Cumberland, July 30, and brought back and locked up in the central police station. The arrest took place at the Queen City Hotel, where he had registered as "Dr. W. A. Edwards, of Detroit." He had shaved off his red mustache. He entertained the members of the profession in Cumberland as lavishly as he did the Baltimore physicians. He had no money when arrested, but had on his bureau a picture of Baltimore surgeons with himself as the center of the group. He claims to be from Vienna, and to have been traveling in the United States for two and one-half months. On his return to Baltimore he was committed for court in default of $1000 bail, on a charge of defrauding the Stafford Hotel. He seemed considerably worried, but had little to say. After his measurements had been taken according to the Bertillon method, and his photograph had been secured for the rogue's gallery, he was consigned to jail. "They don't do all this in the old country," he said.

ILLINOIS.

Dr. Walter Garrey, Aurora, a graduate of Rush Medical College, 1900, has been appointed professor of physiology in Cooper Medical College in San Francisco.

Chicago.

Dr. Henry Hooper is spending a few weeks at Marquette.

Dr. A. D. Bevan is spending his vacation at Manchester-by-the-Sea, Mass.

Col. A. Hartsuff, medical director of the department of Missouri, left a few days ago, to inspect the posts in the Department of the Lakes.

The city health officers think that the terrible infant mortality of summer is largely due to uncleanliness in the house and its surroundings. "Wholesome food for the young can not be furnished from an unclean, sour-smelling kitchen."

Dr. Reynolds, commissioner of health, hunted up and condemned 75,000 pounds of poultry on August 6. It had been through a fire in St. Paul, and was hence damaged. This is one of the largest condemnations ever made by the health department.

The city mortality for the week ended August 4, was 484, compared with 438 of last week, and 465 for the week ended Aug. 5, 1899. For the first time in any week since that ended Dec. 28, 1898, there was no death from scarlet fever. Scarlet fever appears to be "losing its evil significance for the sanitarian and health authorities." Acute intestinal diseases head the list with 136 deaths. This increase is due probably to high temperature rather than to impure water, as is shown by the increased number of deaths of infants. Consumption carried off 42, but usually heads the list in winter; next come heart and nervous diseases, each with 32 deaths; pneumonia, 19; sunstroke, 2.

NEW YORK.

Dr. George Chanton, Kings Park, has been appointed first-assistant physician in the Long Island State Hospital.

The second annual meeting of the "Physicians of the Lake Keuka Region" will be held at Grove Springs, Lake Keuka, on August 14 and 15. An interesting program has been prepared.

SYRACUSE UNIVERSITY COLLEGE OF MEDICINE.

No changes for the coming year have been made in the full professorships, but a number are announced in the staff of instructors and lecturers. Dr. C. E. Coon has been made director of the anatomical laboratory; Dr. William J. Wallace has been promoted from instructor to lecturer in anatomy; Dr. Eugene Belknap, in addition to being instructor in medicine, has been made director in clinical obstetrics; Dr. Frank Knowlton has been promoted from instructor in physiology to lecturer on that subject; Dr. Robert Pierson has been made assistant in clinical obstetrics in addition to being instructor in histology; Dr. Albert Hotaling has been elected assistant in clinical obstetrics; Dr. A. E. Larkin, instructor in clinic medicine, and Dr. A. J. Abeel, demonstrator in anatomy.

INDIANA.

Physicians of New Albany have discovered several cases in which children were suffering from formaldehyde, used in milk.

The Elkhart physicians are wisely forming an organization looking to their protection against those who are negligent in settling their "doctor' bills.

Dr. M. A. Boor, the official smallpox physician of Terre Haute, has been dismissed, as there are no more patients. The first case occurred January 17, and since then there have been fifty-four others. About $5000 has been expended in exterminating the epidemic.

The attending physician at the Indianapolis Orphans' Home filed death returns for three infant inmates of the institution, giving the cause of death as inanition, but on a marginal note, expressed his belief that formaldehyde used in the milk furnished to the institution was responsible for the deaths.

MICHIGAN.

Dr. Fred Sovereign, of Three Oaks, has been nominated for senator on the Republican ticket.

Dr. Minta P. Kemp has been appointed on the staff of the Northern Michigan Asylum for Insane, at Traverse City.

Including reports by regular observers and others, consumption was reported present in Michigan during the month of July, 1900, at 175 places; measles at 123 places; scarlet fever at 100 places; typhoid fever at 83 places; diphtheria at 37 places; whooping-cough at 37 places; smallpox at 9 places, and cerebrospinal meningitis at 8 places.

WISCONSIN.

A new isolation hospital has been completed at West Superior.

Dr. J. M. Allen, of Milwaukee, was relieved, August 6, by P. A. Surgeon Herbert Blue, who came recently from Genoa, Italy. Hitherto all lake sailors and marines have been sent to Chicago for treatment. Milwaukee's rating in the United States Marine-Hospital Service has been changed from third to second class.

OHIO.

In Columbus, the district physicians, under the readjustment of affairs of the health department, must live or have their offices in the wards in which they expect to serve the city.

It is stated that twenty or more physicians of Columbus have decided to form a protective association, and henceforth unless patients pay their bills they will refuse to attend them. They say that they have accounts on their books against people who are abundantly able to pay.

DISTRICT OF COLUMBIA.

Dr. William C. Woodward has been reappointed health officer of the District, which office he has filled for the past six years.

Dr. John G. Cecil has been elected professor of materia medica and therapeutics in the University of Louisville, vice Dr. William Bailey, resigned.

UTAH.

Dr. B. W. Mather, house surgeon of St. Mark's Hospital, Salt Lake City, has resigned and Dr. H. C. Deane, formerly house physician, will take his place. Dr. Carol Landenberger, of Philadelphia, will be house physician.

MAINE.

Dr. Freeman H. Chase, Bangor, is spending his vacation at Northport.

Dr. John F. Hill, Augusta, has been nominated by the Republican party for governor.

KENTUCKY.

Dr. J. N. McCormack, secretary of the State Board of Health, on August 1, gave a lecture on hygiene, to the physicians of McLean County, and also organized a local medical society.

WASHINGTON.

Dr. W. C. Cox, Everett, has been appointed a member of the State Board of Medical Examiners to take the place of Dr. Van Zandt, whose term has expired.

MASSACHUSETTS.

Dr. William W. Hartwell has been appointed house physician at the Malden Hospital.

NEW JERSEY.

Governor Vorhees, on July 31, appointed Dr. H. W Elmer, of Trenton, a member of the State Board of Health, to succeed Dr. Franklin D. Gaump, deceased.

SOUTH CAROLINA.

The Medical Society of South Carolina has placed "its stamp of approval" on the water of the Edisto River, for supplying the city of Charleston.

VIRGINIA.

Dr. Cunion G. Williams, Richmond, has been elected professor of histology, pathology and bacteriology in the medical college of Virginia.

IOWA.

Dr. Peter Bassoe, of the Mount Pleasant Insane Hospital staff, has resigned, and intends visiting Europe.

CALIFORNIA.

Dr. E. J. Hennessy, Napa, has been appointed as one of the board of managers of the Napa State Hospital.

RHODE ISLAND.

Dr. George W. Jenkins has been elected president of the Woonsocket Hospital corporation.

GEORGIA.

Dr. Ralston Lattimore, Savannah, has gone to Europe for a two months' trip.

MONTANA.

Dr. A. C. McClanahan, Red Lodge, has gone to Europe, to remain a year.

CANADA.

Dr. Ogilvy, Montreal, has been appointed house surgeon at the city hospital, Blackwell's Island, N. Y.

Concerning smallpox in Montreal, the last quarantine was raised on August 2, and all the cases are said to be progressing favorably.

Dr. Chestnut, superintendent of the Winnipeg General Hospital, has gone to Europe for a year's study. During his absence the affairs of the hospital will be administered by Dr. Trick.

General Manager Hays, of the Grand Trunk system of railways, has appointed Dr. J. Alexander Hutchinson, of Montreal, chief surgeon of the lines west of the Detroit and St. Clair rivers.

Dr. Laberge, medical health officer of Montreal, has gone to Paris to attend the Exposition. While there he will pay particular attention to all matters pertaining to sanitation, and to the health and well-being of great cities in particular.

One of the graduates in medicine this year at Laval University was a Syrian, Nagib Abdow. He has proceeded to Paris, where he will take a two years' course in surgery, after which time he will return to his native land to practice his profession.

The Department of Inland Revenue will make another collection of alum baking-powders in December for analytic purposes. After that manufacturers of these powders will be prosecuted if an attempt be made to continue putting them on the market.

Dr. Edgar A. Grafton, a promising young physician of Montreal, was drowned last week while bathing, four miles below the city, in the St. Lawrence. A house surgeon of the Kingston Hospital met a similar fate while canoeing amongst the Thousand Islands.

A congress of French-spea [illegible] 'cian [illegible] rgeons
America is proposed by the [illegible] cal [illegible]
proposition is to have it as [illegible] ee [illegible]
of the semicentennial of [illegible] ty,
college in the country.

Dr. James H. Richardson, emeritus professor of anatomy in Toronto University, celebrates his golden wedding this week. He received his M. B. degree in 1848 and was appointed professor of anatomy in 1850. About four years ago he resigned and was placed on the emeritus staff.

AMBULANCE DOCTORS FOR TORONTO.

Although for years past there has been some agitation for the appointment of properly qualified physicians on our ambulances, no decisive step has been taken, and the appointments are now again being proposed. There would probably be a few objections raised to these appointments from citizens, and every day their necessity seems more apparent. Since the establishment of the emergency hospital down-town, doctors are not by any means called so frequently to accidents. From all over the city the victims of these accidents are hurried to the emergency hospital, without any surgical assistance, except what a policeman trained in "first aid" can render. It is expected that the question will be discussed at an early meeting of the Board of Police Commissioners.

CANADIAN MEDICAL ASSOCIATION.

The profession in the City of Ottawa are bestirring themselves to make the coming meeting of the Association in the capital city a pronounced success. This Association was first organized in 1867 in the city of Quebec, with the Hon.—now Sir —Charles Tupper as its first president. This position he held for three consecutive years, and the following gentlemen have since succeeded him: The Hon. D. McN. Parker, Halifax; Sir James Grant, Ottawa; William Marsden, Quebec; Le Baron Botsford, St. John; Dr. Hodder, Toronto; Sir William Hingston, Montreal; Dr. Workman, London; Dr. Howard, Montreal; Dr. Canniff, Toronto; Dr. Fenwick, Montreal; Dr. Mullin, Hamilton; Dr. Sullivan, Kingston; Dr. Osler, Montreal (Baltimore); Dr. Holmes, Chatham; Dr. Graham, Toronto; Dr. Ross, Montreal; Dr. H. P. Wright, Ottawa; Dr. J. F. W. Ross, Toronto; Dr. Roddick, Montreal; Dr. Sheard, Toronto; Dr. Harrison, Selkirk; Dr. Bayard, St. John, N. B.; Dr. Thorburn, and Dr. Cameron, Toronto, and this year Dr. R. W. Powell, Ottawa. From 1870 to 1875, inclusive, the average attendance was 57; from 1876 to 1881, 68; from 1882 to 1887, 80; from 1888 to 1893, 98, and from 1894 to 1899, 134. This shows a good healthy increase, indicating that the association is continuing to prosper and grow in favor with the profession. As regards the papers for the coming meeting the general secretary states that they will be numerous and instructive. It is expected that Dominion Registration will be discussed for the last time and unanimously approved by this association.

THE SEWAGE FARM VS. SEPTIC TANK FOR TORONTO.

The city engineer is now busy preparing his report on this subject to be presented to the first meeting of council after vacation. Toronto must soon grapple with this question in municipal politics. Toronto has an unusually large consumption of water daily, the average exceeding twenty million gallons, and it is stated that the quantity of sewage to be disposed of is greater than in most cities of like population, though less offensive and perhaps easier to deal with. With a population of 225,000, Toronto has as great a quantity of sewage to deal with as Berlin, Germany, which possesses the most complete and up-to-date outfit as regards sewerage system and sewage farms. The daily press has been laying the matter pretty clearly before the people, contrasting the sewage farm and the bacteria treatment; and as the medical health officer has been urgently and persistently advising the council to proceed with this work, we may expect that the autumn will see the question grappled with in a way that will redound to the health of Toronto's citizens.

MARINE HOSPITAL NOTES.

Quarantine in the Philippines.—This station having been placed under the Marine-Hospital Service by executive order, the former Spanish quarantine station at Mariveles Bay, near Manila, has been transferred to the Service, and P. A. Surgeon Perry, now on duty at Manila, is remodeling same and equipping it as a model quarantine station.

Yellow Fever in Florida.—A telegram has been received from Surgeon White, who is on an inspecting tour in Florida, stating that the health officer of Hillsboro County, Fla., had wired the state health officer of the presence of two cases of yellow fever in Hillsboro County. Surgeon White and the state health officer started for Tampa at once. A subsequent telegram from State Health Officer Porter states that there are three cases. From the present knowledge of the situation the Surgeon-General is unable to say whether the fever will become epidemic.

Formalin Disinfection.—A bulletin has just been issued by the Hygienic Laboratory on formalin disinfection of baggage without apparatus. This work was undertaken on account of the rather widespread use of formalin for the disinfection of baggage by sprinkling it on clothing in trunks, or by pouring it on absorbent material in the corners of a trunk. Conclusions reached by experiments are that the method is not a good one, and, while sprinkling formalin on baggage in a trunk or box may be depended upon to kill non-spore-bearing organisms, such as typhoid and diphtheria, through three layers of blankets, it can not be depended upon to kill anthrax spores through one layer of blanket. However, the quarantine regulations of the United States require the use of chemical and physical agents sufficient to destroy spores.

Correspondence.

Rambling Notes of a Roving Doctor.

Paris, July, 1900.

MEDICAL MATTERS IN VIENNA AND PARIS—TUBERCULOSIS.

To the Editor:—Nothnagel gave us five lectures on the subject of tuberculosis. He discussed the disease in its different manifestations, and asserted that there were few people living who had not in some part of their economy living tuberculous germs. The old idea that phthisis pulmonalis was always a fatal malady was proved by the many autopsies that showed the existence of healed cicatrices in lung tissues that had been invaded by the specific germ. In his treatment he ignores the use of all drugs almost entirely. The hygienic management and the selection of a desirable climate are the only curative agents upon which he places any confidence. In his choice of a climate, one as free as possible from dust and germs should be selected, very little attention being paid to temperature. Medication is restricted to such agents as aid in the digestion and assimilation of food. Creosote, in some cases, if given in moderate doses, he thinks is of benefit but only in so far as it may act as a stomachic and intestinal disinfectant. To fulfill these indications, however, one prefers the carbolate of guaiacol, which he uses to correct any putrefactive changes that may be going on in the alimentary tract. Cod-liver oil, he thinks, is only applicable to those patients who can not eat and digest fatty articles of diet, and these comprise but a small percentage of phthisical subjects. The raw meat treatment of tuberculosis is at present exciting considerable interest in medical circles in France. More than thirty years ago, a physician of Montpellier presented before the Paris Académie des Sciences a paper entitled, "Sur un Nouveau Traitement de la Phthisie Pulmonaire." In it was given a report of 2000 cases of pulmonary tuberculosis treated by giving from 100 to 200 grams of pounded raw meat in the twenty-four hours. An amelioration of the symptoms followed in a large majority of these cases, and many of them were permanently cured. This treatment, however, was never even given a trial in Paris, at least not by any men of recognized authority in the profession. However, the subject has lately been brought forward in a new aspect, and is, as I before said, attracting a good deal of attention at present. Drs. Richet and Haricourt have made some experiments in which they took 328 dogs and inoculated them with Koch's bacilli. After being thus thoroughly infected the dogs were divided into two groups. One section was fed on raw meat, giving a dog of average weight 120 grams in the twenty-four hours. The other section was fed on a generous mixed diet including plenty of cooked meat. All the dogs in this last section died of acute tuberculosis within six weeks, while those that were given raw meat only, resisted the effects of the inoculation for a long time, even a year or more. The experimenters believe that the good effect of the raw meat is not on account of its nutritive qualities, but that it is a real destroyer of the germ that produces the disease. Healthy dogs fed for a year or more on raw meat were found to be nearly immune against the action of the tuberculous poison.

PLEURITIC EFFUSIONS.

I found the management of these cases to be about the same in all three of the medical clinics in Vienna. An early exploration of the chest is made with a small instrument, to determine the character of the effused fluid. If the fluid is found to be serous in character, the case is treated expectantly, that is, no interference is considered necessary unless the quantity of the fluid becomes large enough to materially interfere with the functions of the heart or lungs. The patient is put to bed, kept warmly covered, and not allowed to take any exercise. No medicines are given unless the case is supposed to have a rheumatic taint about it, in which case it is given the salicylate of soda. Nothnagel says that the cathartics, diuretics, and diaphoretics that are often prescribed with a view of hastening the absorption of the effused fluid are not only worthless, but harmful, as they lessen the vitality and resistance of the patient, and fail to produce the effect for which they are given. When it is thought necessary to draw off the fluid, great stress is put upon the fact that only a small quantity should be drawn off at once. Generally not more than one pint and never more than three should be removed at a single operation. It is claimed that to remove more than the last named quantity is dangerous, and that rmoving only one pint, you are just as likely to have all the balance absorbed, as if you remove more. In this class of cases the aspirator is used to draw off the fluid, and great care is taken to not allow the ingress of air into the pleural cavity.

Furbinger of Berlin teaches and practices a management of serous effusions into the chest walls, in direct opposition to that taught and practiced in Vienna. He taught us that all these effusions into the pleural cavity, however small, should be removed at once.

In his visits around the wards, he always carried with him his exploring syringe, and used it nearly as often as he did his stethoscope. In the pneumonia of children, he said, he had often saved the life of the little patient by drawing off only a few ounces of serum from the chest, and advised us to never treat a severe case of this disease without making a frequent exploration, to ascertain whether or not there was fluid in the pleural cavity. If the effusion is purulent in character, the general rule in such cases is followed, that is, to open up the chest walls and drain.

I find, however, that the practice of resecting a rib or two as a part of the operation, is not as universally practiced as it was some years ago. They are now operating on a good many of these cases by puncturing the chest with a large trocar and canula, allowing the pus to flow off, and then introducing through the canula a rubber drain, and allowing this to remain. I saw this instrument used several times with satisfactory results, one of its advantages being, that it leaves no large, raw surface to become infected, as is the case when the chest is opened with a knife.

PNEUMONIA.

To write on this subject is to discuss one of the most worn-out themes in the whole domain of medicine. However, when we consider that probably at least one-fourth of all persons in the United States who reach the age of 50 years in good health die of this complaint, and that upon the subject of its treatment the great mass of the profession are still entirely at sea, it certainly furnishes a sufficient reason for its frequent discussion among medical men.

The case of the great French surgeon, Péan, will illustrate how the profession look upon a bad case of pneumonia. He was taken with the initial chill, and twenty-four hours later sent for a physician to examine his chest. That physician told him that he had double pneumonia. "That," replied Péan, "seals my doom, for a man above 70 with a double pneumonia always dies." He made his will, then sent for a priest, and prepared for a death that followed only a few days later.

Two decades ago, when opening his lecture at Guy's Hospital on this subject, Dr. Reese said, "In treating of my theme I shall not be able to make a single assertion with regard to this disease, its pathology or its treatment, but some man of equal authority as myself, will give it flat contradiction." Excepting that at the present time we recognize the disease as a specific one, having for its cause a specific germ, the same remark would apply to it to-day as that made by Dr. Reese nearly a quarter of a century ago. For a period of forty years there was kept an accurate record of all the cases of this disease that occurred in the Massachusetts General Hospital, but unfortunately these records teach us only one fact of practical importance, and that is, that however varied the treatment may have been, the mortality of the disease was essentially the same.

Back in the 60s I was following the service of Dr. Bennet, at Edinburgh, in Scotland. We had in the wards several cases of pneumonia which that eminent clinician was utilizing in his bed-side teaching. Among these was one desperate case for which Professor Bennet said there was no hope, and upon whose cadaver we would probably hold an autopsy the following day.

We had a young Swedish physician in our class, who at Stockholm had seen a case of this kind treated by the application of cold to the chest, and he asked the professor if he would allow him to try this plan of treatment on this case. Consent was given and the Swede took the patient in charge. He enveloped the chest in cloths wrung out of cold water, which he changed at first every fifteen minutes, and later at longer intervals. At the end of twenty-four hours the patient was much better, and soon after was on the high road toward recovery. This case, though only a single one, produced a most profound impression upon my mind, and has influenced my practice in this class of cases from that time to the present.

The treatment is not adapted to all types of the disease, especially is it not applicable to old persons with weak hearts, but in vigorous adults and especially among children, I consider in bad cases this remedy superior to all drugs of whatever kind. I think I can say further that after using cold applications to the chest for over thirty years in the treatment of pneumonia, I have saved more lives with this remedy, and had more stubborn quarrels with meddlesome old women on account of its use, than any other agent I have used during that time.

From some cause or other, that I am not myself able to explain, pneumonia during the last decade in my practice, has been a more fatal disease than it was in former years. During my last interview with Professor Furbinger, of Berlin, I asked him if pneumonia in his practice was more fatal than it was fifteen or twenty years ago. He said it was not. When I told him I thought that with us in America it was much more so, he replied, "I am not astonished at that, for you kill your patients with your medicines." He then quoted to me the large doses of quinin recommended by Bartholow and other writers, and commented on our use of the coal-tar derivatives, and wondered why with such treatment we did not kill all our patients. The most enthusiastic man I have ever met, and the one who has the most implicit confidence in his mode of treatment of pneumonia, is Dr. Huchard, a lecturer on internal medicine at the Necker, in Paris, and editor of *Le Journal des Practiciens*.

Mild cases, with no complications, he treats expectantly, but when grave symptoms begin to manifest themselves in the way of a cyanosis of the extremities, or a weak heart, he relies on huge doses of digitalin. He uses from 20 to 30 drops hypodermically of a solution of 1 to 1000 of the drug, two or three times in the twenty-four hours, and relates successes that are something wonderful. Huchard, Like Germain Sée and other French authorities, ignores entirly the use of crude preparations of digitalis, such as the tinctures, fluid extracts and infusions, claiming that they are never reliable, on account of the different amounts of the active principle they contain. In Vienna, the treatment of pneumonia has been considerably modified during the last twenty years. Then as now, hydrotherapy was the agent principally relied upon, but I find the baths used now are of a much higher temperature than they were twenty years ago. Cases that are of a mild or ordinary type are given no medicines at all except a mixture of the yolks of eggs, a little creosote, cognac and cinnamon water to prevent tympanitis, and a drink composed of Vichy water and bicarbonate of soda, which they claim acts to liquify the secretions of the bronchial tubes, and thus prevent the spread of the disease to other parts of the lung not yet involved.

Codein or morphin is given frequently to quiet the cough. Our objection to opiates, on the ground that they dry up the secretion of the bronchial tubes, Nothnagel does not recognize as valid. He says that we let our patients die, worn out by a hacking cough, when often a little morphin given judiciously would save them. Only a couple of baths are given in the twenty-four hours if the case is one of ordinary severity. Temperature, as such, is not usually actively combated, unless such excessive heat of body is accompanied by grave symptoms of a nervous character.

Antipyretic remedies are never given. To combat the hyperpyrexia, baths are given of a temperature of about 90 F., and these baths are repeated every one to three or four hours, according to the severity of the case. On being taken out of the bath, the whole spinal column is sponged off with water of a temperature of 60 F. Great care is taken to disturb the patient as little as possible in giving these baths, and he is lifted from his bed with the sheet into the tub, and back into his bed in the same manner.

They say reserve your whip until your horse begins to tire. If, on the contrary, you begin to use your heart stimulants early, they will have spent their force before they are really needed, and when you resort to them in an emergency they will fail to act. Hypodermics of camphor dissolved in olive-oil, strychnin, digitalis and brandy are the class of stimulants that they rely upon, though the last form of stimulants they give during the whole course of the disease. In bad cyanotic cases a reservoir of oxygen gas is kept constantly by the bed-side, and is given by inhalation at intervals of from one-half to two hours according to the urgency of the symptoms.

A symptom that complicates most severe cases of pneumonia is that of tympanites, and this symptom is most actively combated by the use of the rectal tube and injections into the bowels of small quantities of hot water and turpentin. In the medical service I followed in Naples they were giving from one to two grains of nitrate of silver in the twenty-four hours, as a remedy for pneumonia. The rationale of this treatment I could not comprehend, and I attributed the faith of those who used the agent to that false delusion that associates every recovery we have in our practice with the remedy we have given, however little it may have had to do with the cure of the case.

TYPHOID FEVER.

I believe there are few diseases with regard to the treatment of which there is such a unanimity of opinion among the profession as that of typhoid fever, and this opinion has crystallized down into one of almost complete expectancy. It is true that we have a few men like Dr. Woodbridge, who believe they can materially shorten the duration, and lessen the mortality of the complaint, by an active course of medication, but this opinion is not accepted by the great mass of physicians. My observations in Vienna extend back nearly a quarter of a century, and during all that time, this disease has been treated in the main, hydropathically. The only change that I observe from year to year as I return, is that patients are bathed less and less frequently as time goes on, and the baths used are of a higher temperature. Both in pneumonia and typhoid fever, temperature itself is not regarded as such a paramount symptom and one always to be energetically combated, as it was a few years ago. When, however the temperature reaches 104 F. a bath of about 85 F. is given two or three times in the twenty-four hours during the exacerbation of the fever. In the meantime, if symptoms of a profound nervous character supervene, then these baths are repeated at short intervals until the heat of the body is brought down. To guard against a hypostatic pneumonia, the patient is turned frequently upon his sides, and the spine and posterior aspect of the chest are frequently bathed with alcohol.

The bowels are regulated by rectal injections, but if they become decidedly constipated, a calomel purge is given. Vichy water is given freely to keep up the functions of the kidneys. Milk and animal soups are given to nourish the patient, and in Nothnagel's service, no solid food is allowed until the patient has been without fever for ten days. Some form of alcoholic stimulant is given during the whole course of the complaint; at first, a mild red wine, and if a more active agent is demanded, then cognac is resorted to. Other stimulants, as camphor, strychnin and the like, are only resorted to when the pulse becomes rapid and feeble. In case of hemorrhage from the bowels, an ice-bag is applied. Hypodermic injections of ergotin and morphin are given, and if the bowels will tolerate it, a few ounces of a 5 per cent. solution of gelatin is thrown into the rectum.

By what I have written it will be seen that for the management of typhoid fever, in Vienna, there is no treatment other than that of a symptomatic character. In Vienna they tell me that no one has typhoid fever who drinks only water brought from the Semmering. Here in Paris, the conditions are different, for last year they had a wide-spread epidemic of this fever, and I have seen cases of the disease in every hospital I have visited.

At the Andral, one-fourth of all the patients in the male wards were suffering from enteric fever. If you ask a French physician how he treats typhoid fever, he shrugs his shoulders in a significant manner, which means that he does not treat it at all; and he does not, as far as medicines are concerned. Though the plan has only been adopted for a few years, the French in Paris are now treating their cases of this disease with cold baths.

FACIAL NEURALGIA.

I was much interested in Dr. Moyer's late article in The Journal on the use of castor-oil in the treatment of this trouble, and all the more so as we were having some bad cases of this complaint, at that time, in the Allgemeine Krankenhaus in Vienna. Here, Prof. Gussenbauer is given the credit of having first discovered the benefits that are often derived from the administration of cathartics in this extremely painful complaint. As far back as 1886 he had a patient upon whom he intended to operate for the relief of this form of neuralgia.

As he usually does, before any serious surgical interference, he gave the patient a thorough cathardic of castor-oil and cascara sagrada. To the Doctor's surprise the man was so much better on the following day that the operation was postponed, and the cathartic being continued, the case recovered without the use of the knife. The theory entertained here as an explanation of the beneficial effects of this mode of treating facial neuralgia is that it eliminates certain toxic agents from the alimentary tract, which, being absorbed into the circulation, produce this disease.

As an aid in the accomplishment of this result, Gussenbauer later used freely warm-water injections into the bowels, and kept during several days cold applications upon the abdomen. Dr. Breuer, Nothnagel's first assistant, says that he has not found castor-oil better generally than other cathartic agents, and that he often prescribes large doses of calomel followed by one of the salines. But whatever purgative is used, its action must be most thorough, so as to empty completely the entire alimentary tract.

In three cases of this disease that I saw treated in our medical service, it acted well in two, but the third had to be sent to the surgical section to be operated on. I saw Dr. Ricard, of the St. Louis, in Paris, operate for the relief of two cases of obstinate facial neuralgia. He first chisels into the inferior maxillary bone just forward of its angle, exposes the dental nerve and resects about one-third of an inch of the same. He then cuts down upon the facial nerve where it emerges from the bone just under the eye, lifts it up and pulling upon it strongly, resects as much of it as possible. Dr. R. claims that by operating on both nerves in this manner, he does not have to resort to the more formidable operation for the relief of this trouble.

PROLAPSUS UTERI.

Doctor, I suppose you have had many a case of an old lady come to you with a prolapsed bladder, a rectocele and a prolapsed womb. What do you do for this poor, old, suffering mortal? As far as any surgical operation to relieve her is concerned, she is usually dead set against anything of that kind. An ordinary pessary will not remain in place, owing to the relaxed condition of the parts, therefore you must resort to one of the numerous stem instruments that are held in place by being fixed to some appliance that passes around the pelvis, and this appliance is a most uncomfortable one to wear. Among eminent gynecologists the management of this class of cases is as varied as the men you meet.

Schauta, in Vienna, treats these cases by a vaginal fixation and an anterior and a posterior colorrhaphy. His vaginal fixation includes a shortening of the round ligaments. 1. The first step in the operation is to deeply denude an oval-shaped surface that extends from the meatus down to the junction of the vagina with the uterus. 2. Open up into the peritoneal cavity by cutting, not tearing, the tissues that unite the anterior walls of the vagina to the womb. 3. Stitch your severed peritoneal edges to those of the vagina. 4. Introduce a retractor and raise the vesico-vaginal tissues high enough to bring the whole anterior aspect of the womb into view. 5. Catch the round ligament and folding it upon itself, sew the two folded surfaces together. 6. Pass two or three fine silk stitches through the anterior aspect of the womb and, after raising this organ as high up as possible, pass these stitches through the vaginal walls on each side, and tie them tightly. 7. Close up now the balance of your denuded vaginal surface, and this done, you have your anterior colporrhaphy completed. You have now only to do the operation on the posterior vaginal walls, and your case is supposed to be cured.

Terrier, of the Pitié, in Paris, says that this operation is ineffectual, and treats these cases by a ventral fixation of the womb, followed a month later by an anterior and posterior colporrhaphy. I asked the doctor what influence his ventral fixation had on a future labor if the patient became pregnant. He replied by poohing at the idea that it could have any bad influence on the process of parturition. He had probably never seen the report of the discussion of this subject before the New York Academy of Medicine, where the consensus of opinion among some of the best men in America was that this operation should not be done on any woman who was liable to become pregnant.

Richelot operates on these cases by first amputating the cervix if it is much elongated, and then narrowing the anterior and posterior vaginal walls. It is, however, upon the posterior colporrhaphy that he relies, and says that if this is well and thoroughly done, any other operation is scarcely ever needed. In doing this posterior narrowing he begins by making an incision at the margin of the skin, and dissects up a wide flap as high as the junction of the cervix with the vagina. He cuts away all this flap and then closes the parts with a single row of catgut sutures. I asked him if these cases did not often relapse, and he replied that about one in ten did, but a second operation like the last always puts the patient right again.

Where to do a hysterectomy is the rage, as it is here in Paris, one often sees this operation done to relieve the old lady of her prolapsed bladder, rectum and womb. Championnière tells me, however, that in his hands, this operation, to relieve these cases, has been a failure; for after the menopause the uterus is usually so small that it plays but an insignificant rôle in this trouble, and that hence, after you have removed the womb, the walls of the vagina still fall down, which leaves your patient in as bad a condition as she was before she was operated on. W. S. Caldwell, M.D.

Typhoid Fever in Camp.

Philadelphia, July 22, 1900.

To the Editor.—Referring to the correspondence between Dr. Vaughan and Dr. F. R. Packard, in which my name occurs as an authority for the statement concerning the absence of typhoid fever from the camp of Col. Biddle Porter's regiment, I beg to add a word. I pretended at Washington, and pretend now, to no original information on the subject. I cited from memory, with a qualifying phrase as to want of exactness, and an appeal for correction to a fellow member of the Association, the record of this regiment as published by the junior surgeon —Dr. F. R. Packard. This record, as so published, and as repeated by the responsible author in his letter to The Journal, is admitted by Dr. Vaughan to be correct. In the printed report of the discussion as correctly quoted by Dr. Vaughan, my remarks appear without qualification, and in so far as they exceed the record are to be modified.

The point made by me, and for evidence of which the remarkable record of this regiment was referred to, remains unaffected. The volunteer surgeons have been charged with responsibility for the occurrence of typhoid fever in the camps of the United States Army. This charge I believed, and still believe, to be without proof. It is admitted that the sanitation of the camps generally and the control of the men were, to say the least, defective. The question is who was responsible? I affirmed at Washington, and now reaffirm, that responsibility must lie with the executive authority and not with those having only advisory function—with the colonels, therefore, and not the surgeons. In proof thereof we have this one regiment, at least, in which the colonel did as the surgeons advised, and which was practically free from typhoid. Until it can be shown that in other regiments the colonels, the captains, and other line officers—the men having power, and therefore duty—were equally careful in draining and policing the camps in strict accordanace with the advice of the medical officers, it is unjust to assume that the latter were negligent. I have no other interest in the matter than truth and the fair fame of my profession; and I am sure Dr. Vaughan also has the same interests. Yours truly,

Solomon Solis-Cohen, M.D.

A Proprietary Medicine.

Ogden, Utah, Aug. 4, 1900.

To the Editor:—The owners of a certain secret proprietary remedy—known as antikamnia—have recently scattered broadcast among the laity of this city—and probably of other cities —untold numbers of "faith pictures," on the backs of which appear the many indications and explicit directions for the use of the stuff, accompanied by a glowing apostrophe to "Dear Doctor, may your faith never grow less, etc.," which I enclose.

It has long been a mystery to me how sensible physicians could prescribe such substances. The "faith picture" seems especially appropriate in this connection, considering the "working" propensities of both. Very respectfully,

H. B. Forbes, M.D.

Association News.

Is Your Address Correct?

A list of members of the American Medical Association will be published in an early number of The Journal. It is important that this list be correct, and we would, therefore, ask each member to examine the label on his wrapper and, if not correct, notify us immediately so that the name may be correctly printed in the list. Subscribers who are eligible for membership and desire to be enrolled are requested to make application at once so that their names also may appear in the published list.

American Medical Association.

The following are a few of the comments on the last meeting of the Association:

AMERICAN MEDICAL ASSOCIATION.

The meeting held at Atlantic City, N. J., June 5-8, was simply immense—the attendance closely approaching 2500, many of the delegates being accompanied by their wives, the occasion was most enjoyable. The place of meeting, with its many attractions at this season of the year, the hotel facilities, and the arrangements, were all most admirable. The general sessions were a little marred at first by the noisy accompaniments of brass bands on the pier, as well as some other noises from other avoidable sources, which when corrected left nothing to be desired. As a matter of course we can not pretend to give anything like a full report of even the general sessions; the work done, the number and attendance of the sections, will tax to some extent the resources of the Journal of the Association. —*Southern Practitioner*, July.

THE ATLANTIC CITY MEETING.

The Atlantic City meeting of the American Medical Association, held June 5-8, was the most successful, the best on record. More than two thousand were registered as delegates, and not less than ten thousand, including relatives and friends of doctors, were present during the week. . . . The weather was ideal, and Atlantic City is an ideal place for a convention. . . . The best registration facilities on record were furnished, and this partly accounts for the large registration. The writer had delightful experiences on all sides, every prospect pleased and not a single man was vile, but he heard many complaints from delegates on account of overcharging at hotels, the impression being made upon many that they would have fared better had they taken their chances as outsiders and not engaged rooms in advance as delegates.—*Medical Mirror*, July.

THE 1900 MEETING.

The largest, most earnest and industrious, as well as the most profitable and enjoyable meeting of the American Medical Association ever held, was that which convened in Atlantic City last month. It was a grand success, from every point of view. The greatest of health resorts was seen at its best, even the elements being propitious. The local committee surpassed itself in providing entertainments for the members and the ladies accompanying them, and everything was *en fete*. With such a host of attractions and distractions, it would have been scarcely surprising if the work of the sections had been somewhat neglected, and yet in each of them nearly every one of the long list of papers whose authors attended was read to better audiences than usual, and many of the discussions were remarkably interesting. The general sessions were also well attended, and the President's Annual Address, by Dr. Keen, the Oration on Surgery, by Dr. Rodman, that on State Medicine, by Dr. Vaughan, and that on Medicine, by Dr. Witherspoon, were all model papers which were listened to with eager attention. The increasing strength, activity and influence of the Association reflect credit upon its officers, and may well rejoice the heart of every American physician.—*International Medical Magazine*, July.

THE FIFTY-FIRST ANNUAL MEETING.

The fifty-first annual meeting of the national medical organization, held this year at Atlantic City, New Jersey, was the largest and one of the most successful in the history of the Association. The place of meeting was popular, well advertised, and accessible from the large centers of population in the Eastern and Middle States, thus insuring a good attendance. Atlantic City, early enough in the season to avoid the mosquitoes, is a delightful resort, with bracing ocean breezes and nothing to distract the attention from the meeting itself. There was some little complaint that the halls for the various sections were somewhat scattered, thus requiring a good deal of foot exercise on the "board walk," but that was a good fault. A worse fault was that some of the halls were noisy. However, the meetings in the sections, as well as in the general assembly, were largely attended, and excellent work was done. We can not recall ever having known more extensive and interesting programs or heard better papers or discussions. The president's address was a model, and should be read by every doctor in the land. If that portion of it relating to the endowment of medical schools could be circulated freely among people of wealth great good might in time result. One of the features of this meeting was the pathologic exhibit, collected under the supervision of the unofficial committee on pathologic section, of which Dr. L. Hektoen was chairman.

The social instincts of the doctors and their friends had been duly provided for, and the various entertainments and receptions were well attended and enjoyed. Ohio's new medical law created considerable interest and enthusiasm.—*Cleveland Medical Gazetter*, July.

AMERICAN MEDICAL ASSOCIATION.

The officers and likewise the various committees of the American Medical Association are to be highly congratulated on the very successful way in which the fifty-first annual meeting was conducted at Atlantic City, N. J., during the present month. There was nothing to in the least mar the enjoyment or profit of the occasion, the weather was perfect, and the place selected for the various sections was ideal. Atlantic City is itself an island standing out in the sea, and it has two long piers extending far out over the water. On these piers are built several long auditoriums with smaller halls attached, giving ample room for the general session and nearly all section meetings, beside a place for the exhibits. The whole water front connecting these piers, and extending several miles, is traversed by a wide board walk, over which pedestrians can overlook the beach and sea.

The general sessions, which were held each morning at 10 o'clock, were well attended, and a large amount of business was transacted, including numerous improvements in the Constitution and By-Laws. The Constitution and By-Laws were so changed as to limit the papers in any one section to thirty, thus affording more time for discussion. At this meeting, as at many others, the papers were all read very hurriedly, and many of the authors were unable to complete their reading for lack of time. Discussion was very much curtailed in many instances. With the number of papers reduced almost one-half, we should certainly have better and more exhaustive discussions. This is a movement in the right direction.—*The Medical Fortnightly*.

Book Notices.

Injuries to the Eye in Their Medico-Legal Aspect. By S. Baudry, M. D., Professor in the Faculty of Medicine, University of Lille, France. Transated from the original by Alfred James Ostheimer, Jr., M. D., Philadelphia, Pa. Revised and edited by Charles A. Oliver, A. M., M. D., attending surgeon to the Wills Eye Hospital, Ophthalmic Surgeon to the Philadelphia Hospital. With an adaptation of the medicolegal chapter to the courts of the United States of America, by Charles Sinkler, Esq., member of the Philadelphia bar. Cloth, pp. 160. Price $1.00. Philadelphia, New York, Chicago: The F. A. Davis Company. 1900.

The importance of the mediolegal aspects of injuries to the eye are brought forcibly forward by Baudry in this little book. As many injuries to the eye produce different degrees of dimness of vision even to total blindness, and as the same conditions may also be brought about by natural causes, it becomes necessary quite often that the expert witness should thoroughly appreciate the similar and dissimilar conditions as results from trauma or otherwise. While the book is one of only 160 pages, the subject is exhaustively treated and will be of value to ophthalmologists who may be called upon to give expert testimony in the class of cases referred to.

Duane's Medical Dictionary. New (third) edition. A dictionary of medicine and the allied sciences. Comprising the pronunciation, derivation and full explanation of medical, pharmaceutical, dental, and veterinary terms; together with much collateral descriptive matter, numerous tables, etc. By Alexander Duane, M. D., assistant surgeon to the New York Ophthalmic and Aural Institute; reviser of medical terms for Webster's International Dictionary. In one large square octavo volume of 656 pages, with 8 full-page colored plates. Cloth, $3.00 net; full flexible leather, $4.00 net: Lea Brothers & Co., Philadelphia and New York.

The third edition of this compact dictionary is thoroughly up to date, a quality of no mean importance in these times when new names, new products, and almost new sciences are sprung on us every week or two. The old spelling is rigorously adhered to, the diphthongs being as evident as they were in the first edition published. Modern spelling is evidently not heartily endorsed by Dr. Duane.

Clinical Studies in Epilepsy. From the Craig Colony for Epileptics at Sonyea, New York. By L. Pierce Clark, M. D. Paper, pp. 230. Reprinted from Archives of Neurology and Psychopathology.

This volume is a reprint of three long articles from the *Archives of Neurology and Psychopathology*, a publication which we hope will not be discontinued. The first paper, covering more than one-half the book, treats of exhaustion paralysis associated with epilepsy. The author's conclusions are that the theory of exhaustion paralysis is proved both by physiologic experimentation and pathologic data. It is localized to parts participating in the local spasms or confined to those parts most convulsed in the general seizures. This rule will be found to be followed in the great majority of cases. The temporary paralysis may become permanent and it is not necessary to invoke any other state than exhaustion to explain it. It is essentially the exhaustion of cerebral centers, and the severity of the convulsions is not a fair index to its extent. True exhaustion cases dependent on infantile palsy are not common. The differential diagnosis of the two states is extremely difficult but very important, because the exhaustion cases, independent of organic lesions will bridge over the wide breach existing between Jacksonian epilepsy and idiopathic epilepsy. The disorders of motility of this nature suggest some noteworthy points. The degenerative process is closely allied to that of ordinary paralytic states. It must be allowed however, that the epileptic brain is an infirm organ, and we should not charge to the cause of epilepsy more than that which may be due to previous disability of motor centers. He thinks that there is much suggestive of epileptic foci of a paralytic nature in the brain and that different anatomic and physiologic parts may be simultaneously involved. The inefficiency of passive movements, massage, etc., to shorten or prevent epileptic spasms is especially noted in conclusion. The rest of the book is given up to papers on paramyoclonus multiplex, and hypertrophic infantile cerebral palsy and phocomelus as associated with epilepsy, both of which are noteworthy contributions.

Enlargement of the Prostate. Its Treatment and Radical Cure. By C. Mansell Moullin, M. D., F. R. C. S., surgeon and lecturer on surgery at the London Hospital. Second edition. Cloth, pp. 205. Price, $1.75. Philadelphia: P. Blakiston's Son & Co. 1899.

In this second edition the author has omitted a number of operations on the prostate which were described in the previous one and were chiefly of historic interest. Those which he retains he says he knows are of practical value. The book therefore, will stand as giving his recommendation to the measures it includes. We notice that he speaks highly of orchidectomy, but sees little results from vasectomy, which has been lately favored by some prominent writers. In the main, however, the work is one that could be accepted by the profession, not merely on the authority of its author, but as a sensible, practical treatise on the subject.

A Practical Treatise of Diseases of the Skin, for the Use of Students and Practitioners. By James Nevins Hyde, A. M., M. D., professor of skin, genito-urinary, and venereal diseases, Rush Medical College, and Frank Hugh Montgomery, M. D., assistant professor of skin, genito-urinary and venereal diseases, Rush Medical College. Fifth and revised edition. Illustrated with three engravings and twenty-four plates in colors and monochrome. Cloth, pp. 863. Price, $4.50. Philadelphia and New York: Lea Brothers & Co. 1900.

As the publisher states, the history of this work is one of growing appreciation and success; the last edition has been entirely exhausted within two years. The author has added new chapters on porokeratosis and blastomycetic dermatitis, and has generally revised a portion of the work and eliminated certain portions which seemed to him of less value. Twelve full-page plates and two engravings have been added to the illustrations. There is no doubt that this revision will maintain its deserved favor with the profession.

Medical and Surgical Report of the Presbyterian Hospital in the City of New York. Vol. IV. January, 1900. Edited by Andrew J. McCosh, M.D., and W. Gilman Thompson, M.D. Paper. Pp. 223. New York: Trow Directory Printing and Bookbinding Co. 1900.

This report consists of twenty-two original articles, occupyin 223 pages. The articles deal with subjects of current medical and surgical interest, and are based upon cases treated in the hospital. The report is illustrated with photographs and drawings. From the quality of the articles and the subdivisions of the medical board and of the staff of the pathologic department, it is seen that this hospital is well organized and equipped. Medical and surgical registrars are provided for, and good arrangements have been made for securing and classifying the clinical records—a fundamental requisite for proper study of the material. The pathologic department has a large staff of workers.

International Contributions to Medical Literature. "Festschrift" in Honor of Abraham Jacobi, M.D., LL.D. To commemorate the Seventieth Anniversary of His Birth. Paper. Pp. 496. New York: The Knickerbocker Press. 1900.

The nature of this book is sufficiently indicated by the title. It contains 496 pages, and there are some fifty-seven different articles by about the same number of contributors, the majority of whom are Americans; but Germany, England, France, Norway, Hungary, Russia, Brazil, are represented. The majority of the foreign contributors are Germans. Many of the articles are illustrated; the majority deal with various phases of the medical and surgical diseases of childhood; but not a few are devoted to other subjects. The list of contributors contains many names of prominence. An excellent etching of the recipient of this great honor forms a fitting frontispiece. The preface is a well-written sketch of the manifold, scientific and public-spirited activities of Dr. Jacobi. His brilliant attainments and strong personality certainly warrant this appropriate testimonial in his honor. His services in promoting the study of diseases of children have been of inestimable value to the medical profession.

Plea for a Simpler Life, and Fads of an Old Physician. By George S. Keith, M.D,, LL.D., F. R. C. P. E. Price, $1.25. London: Adam and Charles Black. 1900.

Good, wholesome criticism is always a benefit to the one criticised, if the criticism is made and accepted in the right spirit. This remark applies to a profession as well as to an individual. The "Plea for a Simpler Life, and Fads of an Old Physician"—two books in one—is more than a criticism, it is an indictment of the medical profession by one who was once a member of it. And we must confess that some of the items in the "bill of particulars" are founded on good grounds, and therefore, the plea of "guilty" must be admitted. The author, a brother of the well-known surgeon, the late Thomas Keith, of Edinburgh, was associated with Sir James Y. Simpson, and at one time was proud to be a member of the medical profession. But now he neither proclaims the honor, nor acknowledges the pride. In spite of the fact that he says some harsh things of them it would be a good thing if all physicians would read his book. It is full of good common sense and practical wisdom, and, above all, much of what it contains is truth. His great plea is for plainer living, for less food, especially in sickness, and for less drugs. His protest against forced feeding should be read by every thinking physician. His fads are innocent, but nevertheless valuable ones in their places. The author is an extremist in many ways, and many of his statements are to be resented, still, in these days of high living, which is the cause of so many of the prevailing diseases, the book is well worth reading.

The Refraction of the Eye. A Manual for Students. By Gustavus Hartridge, F.R.C.S., Senior Surgeon to the Royal Westminster Ophthalmic Hospital. Tenth Edition. Illustrated. Price, $1.50, net. 12mo. Philadelphia: P. Blakiston's Son & Co. 1900.

The fact that this work has reached the tenth edition in six years tells its own tale. As its title indicates, it is concerned only with errors of ocular refraction and the fitting of glasses, ophthalmic diseases and operations being excluded. The work appears to have been thoroughly revised and additions made to keep it scientifically up to date. The metric system is used throughout.

One pleasing feature is that the chapter on retinoscopy has been divided into two parts, explaining the use of concave and plane mirrors, respectively. It thus prevents the [illegible] being misled by teachings that are not in[illegible] ular mirror, for the reason that the [illegible] are reversed in the use of the two reflecto.

The Principles of Treatment and Their Application in Practical Medicine. By J. Mitchell Bruce, A.M., M.D., F. R. C. P., physician and lecturer on the principles and practice of medicine, Charing Cross Hospital. Adapted to the United States Pharmacopeia by E. Quinn Thornton, M. D., demonstrator of therapeutics, pharmacy, and materia Medica, Jefferson Medical College. Philadelphia. Cloth, pp. 614. Price, $3.75. Philadelphia and New York: Lea Brothers & Co. 1900.

We have here an English work revised and adapted to the American Pharmacopeia. The author was led to its production by observing the difficulties which most students, especially those who have received a modern education in medicine, find in adapting themselves to the practical treatment of disease. He has used here the course which he has followed in his teaching in the class-room and at the bedside, calling the attention of the students, first, to the objects of treatment, and afterward discussing the selection of medicinal and non-medicinal measures required. The first part of his book, therefore, is a general discussion of the principles of treatment, founded on etiologic, pathologic, and clinical character and the cure of the disease, the personal factor in the patient, and the proper relation of therapeutics to medicine. The two concluding chapters of this section deal with the means of treatment, food, rest, exercise, and with therapeutic procedure. In the second portion we have a number of leading diseases thus taken up and discussed. There are separate chapters for each of these, with the general symptoms and indications of the disorder, followed by outlines of practice with general directions as to the measures to be taken from the first visit, containing also formulas that will be of value. The book will find its place and use in the library of the young practitioners, and many older ones may also find it suggestive.

Horseless Vehicles, Automobiles, Motor Cycles. Operated by Steam, Hydrocarbon, Electric and Pneumatic Motors. A Practical Treatise for Automobilists, Manufacturers, Capitalists, Investors, and Everyone Interested in the Development, Use and Care of the Automobile, Including a Special Chapter on How to Build an Electric Car. With Detail Drawings. By Gardner D. Hiscox, M.E. With 316 Illustrations. Price, $3.00. New York: Norman W. Henley & Co. 1900.

If automobiles ever become practical on all kinds of roads, physicians as much as any class will be benefited. No matter what the future may develop, it can not yet be said that the horseless carriage is able to take the place of the old, reliable four-footed motor. Nevertheless in the cities, and where there are good roads, the horseless carriages are becoming quite popular, and many physicians who are favorably situated are investigating and using them. The literature on the subject is not at all voluminous as yet, and for this reason if for no other this work of Hiscox ought to have a large sale. It gives the history of the progress of the horseless vehicle from the beginning, covering steam, electricity, hydrocarbon vapor and compressed air as the motive power. It is fully illustrated, the illustrations containing full and minute details of the construction of practically all classes of motor vehicles made in this country or Europe, together with half-tones of all the most important kinds of the vehicles in use in the different countries. The detail of construction is gone into fully, almost too much so for those not versed in mechanics. But as a full understanding of all the parts and mechanism, even to the smallest details, is necessary for those who expect to run them, this is of decided advantage after all. The management of the various motors is also thoroughly explained.

Deaths and Obituaries.

Elisha Chenery, M.D., died at his home in Boston, August 1, aged 71 years. He was graduated from Harvard Medical School in 1853 and practiced in Maine until 1862, when he entered the army as a surgeon. He was soon obliged to resign on account of ill health and return to Maine. In 1866 he returned to Massachusetts and practiced in Cambridge and Boston until shortly before his death. He was a member of the local medical societies and of the American Medical Association. From 1876 till 1880 he was professor of pathology and therapeutics and dean of the faculty of the Boston Dental College, and from 1881 till 1885 professor of the principles and practice of medicine in the College of Physicians and Surgeons, Boston.

Benjamin Howard, M.D., died recently in Elberon, N. J., aged 64 years. He was graduated from the medical department of the University of New York in 1858. After serving as surgeon in the Civil War, he practiced his profession in New York City, where he was professor of surgery in the Long Island College Hospital and lecturer on the same subject in the University of New York. In 1877 he was made a member of the Royal College of Surgeons of England, and two years later a Fellow of the Royal College of Surgeons of Edinburgh.

Samuel A. H. McKim, M.D., of Washington, D. C., after an illness of two years, died July 26 at the age of 74. He was graduated from the National Medical College—Medical Department of Columbian University—in 1852, and practiced continuously in Washington until 1898, with the exception of the time of the Civil War, for which he was one of the earliest volunteers. He served for a quarter of a century as surgeon to the police department and from 1890 till 1898 he was captain and surgeon in the National Guard of the District of Columbia.

Richmond Joseph Southworth, M.D., College of Physicians and Surgeons, N. Y., 1866, died in Washington, D. C., August 2. He was a son of Mrs. E. D. E. Southworth, the well-known novelist. During the Civil War he was an acting assistant-surgeon, U. S. A., and subsequently served on the staff of the Nursery Hospital, Randall's Island, N. Y., as well as on that of St. John's Riverside Hospital, Yonkers, N. Y. He was located in Yonkers until his removal to Washington.

Buell G. Streeter, M.D., died in Glenns Falls, N. Y., July 25, aged 68 years. During the Civil War he was assistant-surgeon of the Ninth New York Cavalry, surgeon of the Fourth Cavalry, and medical director of the Army of the Shenandoah. When the army was mustered out he located in Granville, but two years later moved to Glens Falls, where he had since practiced.

Elizabeth L. Denel, M.D., died at Harper Hospital, Detroit, Mich., after a short illness, August 1, aged 55 years. She was graduated from the Medical Department of the University of Michigan in 1875, and since resided in Detroit. She was an earnest, progressive worker in her profession and was an active member of the Protective Agency for Women and Children.

Harved C. Brown, M.D., Old Town, Maine, died suddenly at Foxcroft in that state, from heart disease, July 27. He was graduated from the Medical Department of Bowdoin College in 1895, and served as surgeon to the Canadian Pacific Railway for two years, after which he located in Old Town.

William Joseph Woodruff, M.D., who had practiced in Providence, R. I., since 1896, died of heart disease in that city July 28, aged 30 years. He was graduated from Albany Medical College in 1894, winning the Vanderpool prize of the year, and an interneship at the Albany General Hospital.

Louis G. Voigt, M.D., Freeport, Ill., died from gastric ulcer on August 1, aged 59 years. He was graduated from the New York University Medical College in 1866, and at once located in Illinois. He was county physician for several years and a member of the Stephenson County Medical Society.

W. S. Matthews, M.D., Fort Madison, Iowa, was found dead July 31, aged 49 years. The verdict of the coroner's jury was "apoplexy superinduced by heart disease." He was graduated from the College of Physicians and Surgeons, Keokuk, Iowa, in 1882.

J. A. Houtz, M.D., died at his home in Loganston, Pa., July 24, aged 54 years. He was graduated from Jefferson Medical College in 1871 and, with the exception of one year spent in Philadelphia, he had practiced his profession in Loganston.

George Edelmann, M.D., a graduate of Jefferson Medical College, died at the City Hospital, St. Louis, Mo., on July 19. He was a surgeon during the Civil War, and claimed a share in the experiments which led to the discovery of chloroform.

James McConaughy, M.D., died in York, Neb., July 18, aged 90 years. He was graduated from Jefferson Medical College in Philadelphia. He practiced medicine in Mt. Pleasant, Pa., for forty-five years, and in 1886 removed to York.

Paul M. Day, M.D., Detroit, Mich., died from overdose of aconite, August 1, aged 29 years. He was graduated from the University of Michigan in 1893 and from the medical department of the University of Pennsylvania in 1895.

John L. Howell, M.D,. died in Morristown, Tenn., on July 30, from carbuncle. He was 46 years of age, and was graduated in 1877 from Louisville, Ky., Medical School, and practiced thereafter in Morristown and Knoxville, Tenn.

Thomas J. Boyles, M.D., who had practiced in Houston, Tex., for the past twenty-seven years, died there July 22, aged 50 years. He was graduated from the Medical Department of the University of Alabama in 1871.

David A. West, M.D., Lexington, Mich., died August 1 from cancer of the liver. He was graduated from Trinity Medical College, Toronto, in 1866, and had practiced in Lexington for nearly thirty years.

Frederick W. Hulseberg, M.D., acting assistant-surgeon, U. S. A., was killed at Majajay, Luzon, P. I., August 1. He came from New Haven, Conn., and had arrived at Manila only six weeks before.

J. N. Sipe, Booneville, Ark., died on July 26. He was a graduate of the medical department of Vanderbilt University, Nashville, Tenn., of the class of 1876.

Peter C. Rundio, M.D., of Williamsport, Pa., died August 1, aged 76 years. He was graduated from Jefferson Medical College, Philadelphia, in 1852.

M. G. Curtain Englar, M.D., a graduate of the Baltimore University School of Medicine, in 1898, died in that city July 30, at the age of 27.

Raphael A. Edmonston, M.D., assistant-surgeon, U. S. A., died June 2, in the Second Reserve Hospital, Manila, P. I., from blood-poisoning.

J. M. Jeffries, M.D., who had practiced medicine for fifty years in Scottsville, Albemarle County, Va., died July 29. He was 70 years of age.

James Stoughton, M.D., passed assistant-surgeon U. S. N., was drowned at Shanghai, August 5. He was with the gunboat *Castine*.

Sanford G. Riley, M.D., of Hamilton, Ga., died August 1. He was graduated from the Atlanta Medical College, in 1879.

R. Fargus Carmichael, M.D., house surgeon at the General Hospital, Kingston, Ont., was drowned on July 28.

DEATHS ABROAD.

The death of Dr. E. Anders, June 23, is reported from St. Petersburg. He was the well-known Russian authority on pediatrics and orthopedics, although he had barely reached his fiftieth year.

Dr. H. Dohnberg, professor of ophthalmology at St. Petersburg, was shot and killed by a military officer to avenge a private injury, according to accounts in the lay press.

The death is also announced of the Danish professor of chemistry, Dr. J. Kjeldahl, whose name is familiar by his method of estimating the amount of nitrogen in the urine.

Norbert Fafard, M.D., professor of chemistry and toxicology in the University of Laval, Montreal, died recently, aged 53 years.

George S. Gregory, M.D., M.R.C.S.E., Kensington, Eng., died July 9, aged 88 years.

Progress of the Plague.—A telegram from Constantinople states that the bubonic plague is spreading rapidly at Symrna, seventeen new cases, and seventeen deaths since the last report. The *Gaz. Méd. de Paris* observes that many of the steamers in the eastern Mediterranean have no appliances for distilling water, and that the ships obtain their supplies from shore as usual, although the plague is officially announced at Aden, Suez and Port Said.

Thirteenth International Medical Congress.

Held at Paris, France, August 2 to 9, 1900.

(By Cable from our Special Correspondent.)

Paris, Aug. 3, 1900.

The Congress convened for its inaugural session at 2 o'clock, August 2, in the magnificent *Salle des Fetes* in the *Champs de Mars*. The hall, while grand, was too large, and it was difficult to hear the speakers. President Loubet, who had been expected to welcome the members of the Congress, was unable to be present on account of the assassination of the King of Italy.

Prof. Lannelongue, president of the Congress, in his address applauded the usefulness of international gatherings of physicians on account of the mutual interchange of ideas, etc. He advocated a universal classification of medical terms. This was gradually being accomplished, and no divergence from *recognized language—no volapük—was required for this purpose*. It was the pride of France to consider that the first International Medical Congress was held in Paris—in 1867. The results of the closing century in medical progress and research had been marvelous, and the harvest was now being gathered.

M. Monis, minister of justice, then addressed the Congress, welcoming the members on behalf of the government.

Dr. A. Chauffard, secretary-general, made a report of the work done by his department in the organization of the Congress. He announced that it had a membership of 6000, of whom 350 were Americans, and that 260 reports and 1200 communications had been received.

Addresses were then made by delegate representatives of the various nations: Von Bergmann, Germany; Albert, Austria; Sir William MacCormac, Great Britain; Kitasato, Japan; Stokvis, Holland; Jonnesco, Roumania, and Riverdin, Switzerland. No reply was made on behalf of Italy, on account of the national bereavement.

Prof. Virchow, Berlin, then delivered the first scientific address of the Congress on "Traumatism and Infection."

In the section of Dermatology and Syphilography, the first subject for discussion was "The Parasitic Origin of Eczema." Unna, of Hamburg, criticised the classification of the cocci as insufficient and artificial, and recommended one based on special methods of coloration. The etiologic rôle of the parasite should be tested by inoculations. He had found numerous micro-organisms in eczema, which, on inoculation, reproduce the disease. The work of the future should be along these lines. Eczema is a contagious disorder and is probably under certain conditions epidemic.

James Galloway, London, had found cocci in eczema, though he has not sufficient evidence to consider them positively the specific origin of a disease. The later origin is probably staphylococcus aureus, but more than one factor is at work. The first factor is the predisposition of the skin to the growth of parasites; and the second, imperfect metabolism.

L. Brocq, of Paris, concluded that the vesicular, typical, primary lesion of true eczema is amicrobic; the surface of the eczema is promptly invaded by microbes of secondary infection, capable of creating their own lesions, which are of a microbic nature, and may obscure the symptomatic picture of a condition of which they are never the primary cause.

In the Section of Neurology, Pick, of Prague, read a paper entitled, "Various Points in the Study of Aphasia," in which he considered the auditory and language centers. Ladame, of Geneva, then spoke of pure motor aphasia.

On Friday the subject for discussion in this section was "The Centers of Projection and Association in the Human Brain." Flechsig, of Leipsig, and Hitzig, of Halle, in their remarks, did not agree with, and strongly criticised the views of, Von Monakow, of Zurich.

The first discussion in the [illegible] Th[illegible]s, Pha[illegible] cology, and Materia Medica [illegible] "[illegible] of Bili[illegible] Lithiasis," and was op[illegible] considered, in his remarks, the origin and course of biliary calculi, and pointed out that many of the so-called cures were only apparent, as the disease remained latent, and was liable, later on, to give further trouble. He believes that surgery alone furnishes a complete cure, but that even this was not always certain. Medicinal treatment should be directed toward an increase of the flow of bile.

Gilbert and Fournier, of Paris, detailed the nature of the disease, the cures and pseudo-cures, and the prophylaxis. They thought that mineral water was sometimes efficacious, but agreed that in case of obstruction, the aid of surgery should be invoked. Operations for this condition had been made much less perilous by the recent improvements in technique.

Carvello then read a paper on the "Treatment of Tuberculosis," in which he gave in detail his results following the administration of trioxymethylene, chloral, terpene hydrate, and iodoform, in this disease.

Doleris, of Paris, presented a paper before the Section of Obstetrics on the "Etiology and Nature of Puerperal Infections," in which, after mentioning the heterogeneous infections, he spoke of the autogenesis of puerperal septicemia, due to the transformation of certain so-called saprophytic germs, preexisting in the secretions, and the possibility of their generalization after parturition without new external infections.

Menge and Krönig, of Leipzig, thought that autogenous infection from anaerobic vaginal bacteria was improbable, that it must be rare, and that the prognosis should be favorable. Bacteria from the external genitalia might produce trouble, but no such organisms live in the cervix, the uterine cavity, or tubes. They considered heterogeneous infection the most important, and that air-contact played only a small part. The chief danger lay in the hands of the operator, and the primary seat of infection is found in wounds of the perineum and adjacent structures.

Pestalozza, of Florence, was opposed to vaginal disinfection when the patient was healthy. Even when infection has previously occurred he advises against post-partum examinations, and against uterine and vaginal irrigations.

Paris, August 4.

In the Section of Psychiatry the first subject for discussion under the head of Mental Pathology was the "Psychoses of Puberty." The first paper was read by Marro, of Turin, who stated that hebephrenia caused gastric disturbances. Voisin, of Paris, considered this condition should be distinguished from progressive general paralysis, and Ziehen, of Jena, mentioned the frequency of insanity in youth, and the importance of regular life and habits in the treatment of this condition.

"The Nature and Causation of Tendinous Reflexes" was the first subject of the day in the Section of Neurology. Papers were read by Sherrington, of Liverpool, and Jendrassik, of Budapest, and the discussion was participated in by Van Gehuchten and Roubinovich.

In the Section of "Medicine of Infancy" (Pediatrics), artificial lactation, and, in particular, the use of sterilized milk, was the chief subject of discussion.

Dr. A. Jacobi, of New York, spoke of artificial foods, and said that the results of the analysis of human milk are never identical, and that, therefore, the demand for an exactly equivalent substitute is unjustifiable. Nature is more liberal in allowing latitude than the chemist. Heat both improves and injures milk. Boiled, pasteurized, or sterilized cow's milk is never woman's milk. The process of sterilization is indispensable because it destroys pathogenic bacteria. The artificial food of the infant should be amply diluted, because of the heterogeneous composition of cow's milk. He considers homemade foods preferable to the proprietary foods of the market.

O. Huebner, of Berlin, in considering the artificial feeding of infants, said that the intestine of the child was able to digest cow's milk, but with greater labor than was required for human milk. The greater quantity of proteids presents some difficulties, and the asepsis should be strict.

Monti, of Vienna, in discussing the scientific principles for the production of a food equivalent to human milk, pointed out the difference between the artificial and natural feeding of infants, and mentioned the modification that should be made in cow's milk. The addition of soluble albumin and alkalies, modification of fats, addition of sugar, and neutralization of germs, were among the points noted.

A. Johannessen, of Christiania, made a report on the sterilization of milk, and the way in which it should be used, which covered similar grounds.

G. Variot, of Paris, spoke of the methodic employment of sterilized milk in great cities. In his experience at the Hospital for Sick Children he found that not only healthy children take this food well, but that more than three hundred, who presented more or less marked atrophies, had used it successfully, and furthermore that out of more than eight hundred nurslings they had not a single case of Barlow's disease. Rachitis was very exceptional, but obstinate constipation and anemia were not rare. A. D'Espine, of Geneva, Marfan, of Paris, Escherich, of Graz, and Sevestre, of Paris, joined in the discussion.

On Saturday a symposium was held on "Gastrointestinal Infections and Intoxication of Early Infancy." Escherich, of Graz, described the rôle of microbes in the gastrointestinal diseases of nursing children—ectogenous infections and intoxications—and spoke of the bacteriologic work in that direction which had been done in his clinic. He distinguished between intoxication due to ectogenous decomposition, chyme infection, and infectious diseases of the intestines.

A. Baginsky, of Berlin, considered the subject from the point of view of pathologic anatomy. He classifies these affections as, 1, functional troubles, of which acute dyspepsia is the type; 2, anatomic alterations, which include catarrhal lesions, such as subacute dyspeptic catarrh, infantile cholera, chronic gastrointestinal catarrh, and intestinal atrophy, and folliculitis from the simple form to the grave infectious variety, with dysentery. He then took up the causation of gastrointestinal morbid processes from direct action of intestinal microbes, the action of toxins formed under the influence of these microbes, the action of saprophytic microbes, and from toxic substances in food.

F. Fede, of Naples, had made a particular study of the symptoms and treatment of the chronic forms of gastrointestinal affections and intoxications of nursing children. The dominant symptom is frequent diarrhea. Much may be learned from inspection and examination of the bowel movements, their consistency, odor, presence of blood, micro-organisms, etc. Marked respiratory, glandular, nervous, renal, and cutaneous phenomena attend intestinal intoxication; the clinical forms vary. Hygiene and diet are the first rules of treatment. He then sketched the medicinal treatment, which was, in the main, symptomatic.

Marfan, of Paris, made a report on the etiology and pathogenesis of infantile gastroenteritis. He recognizes four classes of this disease, viz., dyspeptic, primary infectious, primary toxic, and secondary.

In the Section on Surgery of Infancy the first symposium was on "The Treatment of Congenital Luxation of the Hip." The discussion was opened by A. Hoffa, of Würzburg, who spoke of the operative treatment of this condition, and presented the possibilities and advantages of the Hoffa-Lorenz operation.

A. Lorenz, of Vienna, followed with a paper on "The Bloodless Treatment of Congenital Dislocation" at this point, which he prefers to operative treatment, as the latter is still dangerous. Bloodless reduction, under narcosis, overcomes all difficulties which appertain to operative and apparatus treatment. It is performed without instruments, by means of horizontal or vertical extension, the latter being preferable. The anatomic result thus far has been good in about one-half of all cases, but even in the cases where the anatomic results have not been satisfactory, the functional results have been excellent and superior to those following operative interference. Should the bloodless reduction be unsuccessful, the operative reduction by means of arthrotomy can still be performed.

Kirmisson, of Bordeaux, recommends orthopedic apparatus for relief of this condition, applied at an early age. The apparatus he suggests is not based on the plan of Dupuytren's cincture, but takes in the thigh and pelvis and keeps the limbs in moderate abduction. The apparatus is the same as that employed in coxalgia. He considers that the results will demonstrate this to be the treatment of the future for congenital luxation.

Severean, of Bucharest, made a report on cocain anesthesia by injection into the vertebral column. He criticises the method severely. Tuffier gives statistics of 5 deaths in 125 operations in which this method was employed. In one case the death was due to mitral regurgitation. He considers that there may be use for the method when general narcosis is contraindicated.

Dr. Fenton B. Turck, Chicago, in the Section of General Surgery, read a paper on "Prevention of Shock and Infection During Operation," which embodied reports of a series of experiments which show that germs inoculated in animals when in shock proved pathogenic, but when not in shock they were non-pathogenic. Experiments proved that hot applications, made on animals when in shock, resuscitated and no infection resulted. Author is convinced that the application of hot-water bags in the cavity, added to the usual aseptic precautions, will prevent shock and lower mortality after operations.

Ceccherelli, of Parma, read a paper on the "Surgery of the Pancreas." We meet considerable difficulty in its complete extirpation, by reason of its anatomic relations, being deeply placed in intimate connection with other viscera, very rich in vessels and nerves, and discharging a very important digestive juice. The extirpation is not rational if it is to remove a tubercular or syphilitic process. The operation should be executed in such a manner as to leave one of the two canals. Cysts are the most common tumors. Pancreatic calculi should be removed. An affection carefully studied of late is necrosis of the pancreas; necrotic fragments should be eliminated by the surgeon. If the opening of the canal into the duodenum is stopped, a new way may be made. Hemorrhages may take place without wounds, occurring most often after gangrene. The sutures through the parenchyma are tolerated as in the kidneys, liver and spleen. The union of wounds takes place by proliferation of pre-existing cells and especially of the connective tissue. After the complete removal of the pancreas, we find a great development of the glands of Galeati—crypts of Lieberkuehn—and especially a karyokinetic increase of their epithelium, which leads us to suppose, according to experiments of Martinotti, that it can replace the extirpated viscus. The flow of the pancreatic juice into the abdominal cavity does not cause peritonitis, because its absorption is rapid; like the bile, it is harmless if healthy, harmful if contaminated. In the extirpation of the organ, care should always be taken to make ligatures preceding the incision to avoid hemorrhages and out-flow of the juice. The thermocautery and galvanocautery should not be employed, because neighboring parts may be injured by radiation of heat and by scar pressure.

Mayo Robson, Leeds, read a paper on "Pancreatic Surgery." He believes that pancreatic affections are more common than generally supposed. He dwelt on the importance of posterior drainage in acute or suppurative pancreatitis. He has seen fifty-nine cases of cancer of the pancreas, which rarely occurs under 40 years of age. He calls attention to the importance of distinguishing between cancer of the head and tail of pancreas. Hopeless prognosis should not be given till surgery has been tried. For pancreatic cyst he advocates incision and drainage, which he has done in four cases with three recoveries. Pancreatitis he divides into suppurative, hemorrhagic and gangrenous. Bacterial infection is the immediate cause, but gastroduodenal catarrh, injury, and biliary lithiasis must be considered. Chronic intestinal pancreatitis is an important disease and is often mistaken for cancer of the head of the pancreas. The author believes that the time will soon come when disease of the pancreas will be given the attention that it deserves.

Prof. Dieulafoy, Paris, in the section on Internal Pathology, read a paper on "Gastric Ulcerations," in which he notices the prominent types of gastric ulcers, the minute erosion, and the still larger mucosal abrasions—exulceratio simplex—both of which may cause hematuria and in the latter case sometimes fatal ones—the simple ulcer of Cruveilhier (ulcus simplex) with a tendency to hemorrhage and perforation. The specific ulceration of tuberculosis and syphilis may end as this form. Cancer may result from gastric ulcer. The pathogeny of these lesions is not yet fully elucidated; their treatment varies according to the case, medical, specific or surgical.

Ewald, Berlin, in consequence of the resulting perigastritis, considers that surgical interference is the only good treatment.

Cohnheim, Berlin, mentioned the use of large doses of oil in organic or functional stenosis of the pylorus and duodenum.

Mathieu, of Paris, read a paper on "Treatment of Mucomembraneous Colitis," in which he said that constipation is the rule in this disease; indeed, it may be both the cause and effect. A neurotic predisposition intensifies it. Locally, the nervous habit brings on hyperesthesia of the intestines generally and vitiates their mobility; this is especially the cause of the spasms. The disappearance of constipation is at once the sign and warrant of cure. He employs means of cure which do not augment the irritation of the secretions, the painful phenomena and the tendency to spasm. Castor-oil, lavage and belladonna are especially useful. The latter calms the pain and combats the tendency to spasms; more rarely is opium or its derivatives used.

Boas, of Berlin, read a paper on "Symptoms, Diagnosis and Clinical Course of Mucomembraneous Colitis," noticing three forms, viz., catarrhal, mucous colic, and artificial mucomembraneous colitis. The symptomatology is colic, constipation, spasmodic atony of the intestines, membraneous masses in the stool and a general nervous state. The only constant symptom is constipation, and that with the characteristic mucus is the only thing that is pathognomonic. The diagnostician must determine whether it is an idiopathic or complicating affection, and it is also of importance to find the artificial cause. Differential diagnosis is only possible between mucous colic and the other form. The clinical course is parallel to that of habitual constipation. What will correct one, cures the other.

Langenhagen, of Plombières, regards pains as absent in one-fifth of the cases.

Netter, of Paris, stated in a paper on "Acute Non-Tuberculous Meningitis," that we should not insist too strongly on the value of Kernig's sign, namely the impossibility of completely extending the legs when the patient is sitting. This sign seldom fails in non-tuberculous cases, and is observed in the majority of tuberculous cases, hence we can not rely on it as a means of establishing the nature of meningitis. Quincke's lumbar puncture furnishes for diagnosis of meningitis the best instruction. It presents no seriousness provided the withdrawal of the liquid is not made too suddenly. The diagnosis of meningitis will be evident if the liquid is turbid or purulent, or if it contains clots. Very often the liquid drawn appears at first quite clear, but it nevertheless immediately forms a fibrinous coagulum. The hot bath, introduced par Aufrecht, constitutes an excellent means of treatment. In suppurative cases repeated lumbar punctures will render service.

Küster, of Marburg, read the first paper in the symposium on "Conservative Operations in Renal Retention" in the Section of Urinary Surgery. After defining the various causes leading to retention of urine above the bladder, he detailed four groups of conservative procedures: viz., nephropexy, anastomoses, plastic operations with and without resection and partial resection of the kidney.

Fenger, of Chicago, was not present. His paper was read by Turck, of Chicago. [It will appear in an early issue of The Journal.]

Bazy, of Paris, read a paper on the same subject, in which he detailed the obstructions and the means of their removal with critical comments on the various procedures. He considered that the operative results warranted conservatism in this class of cases.

Manquet, of Nice, discussed in the Section of Therapeutics the use of sodium sulphate in dyspepsia. It is useful in constipation in small doses, but its prolonged use is attended by danger.

Blondel spoke of the use of thymus in chlorosis, exophthabnic goiter and congenital debility.

Deschamps, of Rennes, read a pap[illegible] on the tre[illegible] obesity.

A dinner was gi[illegible] at Hotel, at which 120 [illegible] hes by Zweifel, Terrier [illegible]

Professor Lannelongue, President of the International Medical Congress, gave a reception at the Galerie des Champs Elysées Friday evening, to which some Americans with their families were invited. The entertainment provided included music and dancing by the ballet of the Opéra Comique.

Boeck, of Christiania, opened the proceedings of Saturday in the Section on Dermatology with a paper on the "Tuberculides." In opening the discussion on this new doctrine, it is necessary, he said, to distinguish facts from hypotheses. It is established that a series of cutaneous affections exists in tuberculous patients, the constancy of which has been so marked that the affections have been considered to have the same causal relation. The Koch reaction in these cases is, however, inconstant. Hallopeau has given to these the name "toxi-tuberculides." He places these tuberculides in two principal groups: 1. Varieties generally perifollicular and superficial, in a part of which the bacillus is found. This includes lichen scrofulosorum, papulo-squamous and perifollicular pustular tuberculides. 2. Varieties generally not perifollicular, as a rule localized in the skin and in which the bacillus can not invariably be found. This includes lupus erythematosus, papulo-neurotic and nodular tuberculides. There are a number of diseases which it is as yet impossible to group, although they are commonly considered tuberculous. These are acne, indurated erythema of Bazin, angiomatous tuberculides of Leredde, subacute exfoliative dermatitis, and pityriasis rubra of Hebra. He concludes that the limits between cutaneous tuberculosis and cutaneous tuberculides are not clearly defined, and that there is no theoretical or practical reason for placing cutaneous tuberculides in a group by themselves.

Campana, of Rome, believes that it is possible to distinguish clinically between a tuberculide produced by toxins and one produced by the bacillus.

Darier, of Paris, after describing the varieties, etiology, bacteriology, clinical symptoms and pathologic anatomy of the tuberculides, speculates on their pathogeny. He thinks the theory of unknown microbes has no foundation; that the toxin theory does not explain all the facts. The remaining hypothesis is that they are caused by embolisms of attenuated and slightly virulent bacilli reaching the skin by way of the blood channels and then succumbing to the bactericidal influence of their environment. The discussion was participated in by Riehl, of Leipsic, and Lang, of Vienna, who advocated the extirpation of lupus; Finsen, of Copenhagen, who spoke of the treatment by luminous rays; Dubreuilh, of Bordeaux, who mentioned the nasal origin of lupus, and J. Nevins Hyde, of Chicago, who made observations on blastomycetic infections.

Richelot, of Paris, read a report in the Section of Gynecology, on the "Surgical Treatment of Cancer of the Uterus." He believes the vaginal, the route of choice in most cases. The abdominal route has a limited utility, but when applied to invading cancers it is an imprudence, and for limited cancers an illusion. In one, we have an operation always incomplete and only by necessity palliative. By the other route all is removed.

D. de Ott, of St. Petersburg, believes that in every case of cancer, in any part of the uterus, the organ should be extirpated, preferably by the vaginal method. Morcellement is a great surgical advance in the treatment of large cancers. He prefers not to close the wound, but applies a light iodoform gauze tampon. He thinks that by this means the mortality of vaginal hysterectomy can be reduced to the minimum, and during the last six years he has obtained a radical cure in 10 per cent. of his cases.

Thomas S. Cullen, of Baltimore, read a paper on "Treatment of Carcinoma of the Uterus." He referred to the improvement in the operation for carcinoma of the uterus, commencing with amputation of cervix as practiced by Schroeder, abdominal hysterectomy, as done by Pawlik and Kelly; and the radical operation including the iliac glands. Cullen pointed out the danger of implanting carcinomatous into healthy tissue, as is very likely to occur when the radical operation is made. He described the operation in full as made by X. O. Werder, of Pittsburg, in which the chance of implanting carcinomatous tissue is reduced to a minimum. This operation is advised in all cases unless the patient is stout. In adenocarcinoma of the body of the uterus the same operation may be performed, but here the wide removal of the vaginal mucosa is not necessary. An analytic report was made of 176 cases of carcinoma of the uterus, occurring in Johns Hopkins Hospital during the past six years. The prognosis is most favorable in adenocarcinoma of the body; least favorable in adenocarcinoma of the cervix.

Paris, August 6.

Masius, of Liège, in the Section of Internal Pathology, on Monday, read a paper on "Pathogenesis of Acute Pulmonary Edema." The theories of pathogenesis are three in number: 1, the purely mechanical theory, which should be rejected; 2, the opinion of Hamburger and Heidenhain, who consider the lymph-formation a secretory act and the edema merely an exaggeration of this function; 3, the theory of Starling, Winter and Théaulon, who attribute it to modifications of osmosis between liquids in different parts of the area, and to variations in the permeability of the wall. Clinically, pulmonary edema appears in three forms: 1, inflammatory edema; 2, static edema, and 3, toxic edema.

Teissier, of Lyons, declares that a special morbid syndrome exists to which can be given the name of acute edema or serous apoplexy of the lung. It is preceded by a tickling in the throat, painful intrathoracic tension, violent dyspnea, spasmodic and continuous cough, rusty sputum, fine râles, etc. The provocative cause is still to be determined. It may be infection or previous intoxication. Acute and chronic pulmonary edema differ in pathogenesis, symptomatology and prognosis. It may be said that the gravity of an acute pulmonary edema is dependent on the functional activity of the kidneys. He concedes that bleeding is of unquestionable utility in these cases, recommends rectal administration of carbonic acid gas, and thinks that oxycarbonated nitrite of amyl may be employed with advantage. Atropin, morphin and operative procedure he believes valueless and dangerous.

Von Basch, of Vienna, asks and answers the following questions: Under what conditions may pulmonary edema be experimentally produced? What is the nature of the process which causes it? What are the secondary consecutive causes? What is the relation between pulmonary edema, dyspnea and cardiac asthma? What is the relation between pulmonary edema and muscular insufficiency of the right heart?

Huchard, of Paris, urged the value of venesection, Marklen spoke of uremia in connection with pulmonary edema, and Dieulafoy, of Paris, of acute nephritis as a complication.

Perier, of Paris, in the Section of Surgery, reported two cases of old contusion of the head with formation of abscess, in which he trephined with good results. Nanu, of Bucharest, advocated temporary craniectomy in case of abscess. Krause, of Berlin, reported twenty-four cases of intracranial excision of the trigeminus with two deaths, and with good results in the remainder.

Jonnesco, of Bucharest, had excised the cervical sympathetic in 126 cases of epilepsy, exophthalmic goiter, glaucoma. etc.

Chipault, of Paris, reported forty cases of this kind, and 147 vertebral fractures. These statistics were most interesting and indicated the value of modern operative procedure in this class of injuries.

O. Lassar, of Berlin, opened the discussion on Alopecia in the Section of Dermatology on Saturday. He remarked that alopecia has increased progressively during the last ten years. In the case of alopecia areata, there is no predisposition nor is there special resistance in individual cases. Immunity to this condition can not be acquired. Its etiology still awaits a definite explanation. The treatment of alopecia areata is still empirical, founded on a hypothesis, the trial of which has given the most favorable results. Many methods from sublimate and carbolic acid to electricity in its divers forms have been employed with success.

Norman Walker, of Edinburgh, presented the views of British dermatologists on alopecia. He acknowledged the indebtedness of the profession to Sabouraud, of Paris, for his researches on the subject. There are occasionally cases of this disease which are apparently dependent on nerve influence. Hutchinson, of London, regards alopecia areata as a sequel to ringworm; while Crocker, of London, considers that most of the cases diagnosed as alopecia areata are in reality unrecognized cases of ringworm. The infective theory has a strong clinical backing. Dr. Thin, of Scotland, made observations in this direction many years prior to the brilliant work of Sabouraud. In the essayist's observations he has not succeeded in getting the brick-red growth, but has a growth of a deep brownish-black color, apparently due to another organism.

Sabouraud, of Paris, classifies alopecia as follows: 1, infectious; 2, traumatic cicatricial; 3, cicatricial, following inflammatory lesions; 4, diffuse progressive. There are two clinical types, the ophiasic of Celsus and seborrheic of Bateman. He considers this subject one of the most obscure in dermatology, and one which, in the absence of new technical experiments is likely to remain in obscurity for a long time.

Lesser, of Berlin, opened the discussion on the "Causes of Generalized Infections in Blennorrhagia" by saying that generalized infection in blennorrhagia was often encountered in cases attended with complications. The posterior urethra is most often attacked in men. It seems to predispose to general infection, for patients who once have had a general infection are attacked by it anew at each attack of blennorrhagia.

A. H. Ward, of London, discussed the causes of the generalized infections by the gonococcus, which he said could not be separated logically from the local focus whence it originated. There is a continuous interaction, and the persistence of the local disease aggravates the general condition. After study of the process of the struggle for life between the microbe and the human organism, a plan of action for prevention and cure must be deduced. It is still *sub judice* whether the diplococcus of Neisser and its toxin is the sole cause, or whether this infection paves the way for other organisms. Gonorrhea and its associated pathological states are due to the presence of microbes and their toxic products. He had encountered generalizations in 12 out of 2000 cases, or .6 per cent. In closing, he quotes Neisser's words: "It is surely beyond a doubt that the frequency of complications depends on the method of treatment."

F. Balzer, of Paris, stated that general blennorrhagic infection is caused by the blennorrhagic virus, the gonococcus and its toxins which pass into the circulation. It is manifested by general symptoms and by new localizations of the blennorrhagia, sometimes by true pyemia analogous to those caused by pyogenic bacteria. These microbes may be found associated with or superadded to the gonococcus in generalized infection. He then considered the manifestations in which the rôle of the gonococcus was less direct, namely, nephropathies due to general blennorrhagic infection; cutaneous manifestations—erythema, purpura, cutaneous horns; and the various neuropathies. He sums up the subject by saying that the gonococcus is the pathogenic agent not only of mucous blennorrhagia, but also of the general infection. The latter results from direct penetration of the microbe into the circulation and the absorption of its toxins. Experimental research has shown that intoxication plays an important part in the genesis of the manifestations of infection, but the paucity of clinical research does not permit us clearly to differentiate between infection and intoxication. The cases are also too few for definition of the rôle of secondary infections. That rôle seems to be played more and more by the gonococcus.

Neisser, of Breslau, in the same section, advocated dilatation as the best method for examining the urethra.

B. Tarnowsky, of St. Petersburg, read a paper on "Hereditary Syphilis," and presented explanatory tables. He stated that the hereditary influence of the disease is manifested most strongly in the second generation, and that it so markedly decreases in the third generation that the manifestations can not be recognized as those of hereditary syphilis. In the fourth generation there is still further diminution, and therafter no manifestations occur.

E. Finger, of Vienna, admitted the possibility of transmission of syphilis, not only to the first generation, but also to the second, and possibly to succeeding generations. The hereditary consequences of syphilis contracted by parents are true virulent syphilis, syphilotoxic and dystrophic affections and immunity.

Jullien, of Paris, considered the statistics of fecundity of hereditary syphilitics; fetal deaths and abortions; lesions of true syphilis; manifestations derived secondarily from syphilis; dystrophic stigmata; anomalies, malformations and monstrosities. He closed his paper with some theoretical views on the subject.

L. Duncan Bulkley, of New York, in his paper on "Syphilis and Associated Infections," classifies the subject as follows: 1. Double, coincident primary infection—syphilis with a local disease such as chancroid or microbic infection, or with a general disease such as vaccinia, variola, erysipelas, measles, tuberculosis, lepra, malaria, typhoid fever or sepsis. 2. Double subsequent infection—syphilis antedating, with above diseases, seborrhoic eczema, psoriasis, lupus or epithelioma, or postdating, associated with the same diseases. The two infections may retard, accelerate or modify the normal course of either disease.

H. Hallopeau, of Paris, in his paper on the same subject, sums up as follows: Certain infections associated with syphilitic contagion may give place to various hybrids. These are the bacillus of simple chancre, the generative agent of epithelioma and rarely the tubercle bacillus. It is possible but not yet scientifically demonstrated that mixed infection by syphilitic contagion and pyogenic microbes may cause suppurative syphilides which might be called strepto-syphilides, staphylosyphilides, etc. The retention of pyogenic microbes associated with syphilitic contagion and of their toxins may modify the character of the syphilomata—ulcers, vegetations, rupia, etc.—and may create para-syphilitic affections with grave complications. The concomitance of some generalized infections may temporarily modify the course of some febrile disorders and especially of erysipelas.

The second general assembly was held on August 6. In the absence of Professor Pavlov, his address was read by Docent Dr. Lithatchef, of St. Petersburg.

Professor Baccelli did not address the Congress on account of the assassination of King Humbert.

Sir John Burdon Sanderson, of Oxford, delivered an address entitled "Certain Pathological Problems of the Day."

Dr. A. Jacobi, of New York, addressed the Congress on "Medicine and Medical Men in the United States." (Dr. Jacobi's address will appear in an early issue of The Journal.)

The success of the evening reception at the Palais du Luxembourg was marred by bad weather, so that the garden fête could not be held. The reception halls were overfilled by the enormous crowd. The reception was supplemented by a musical performance by the artists of the Opéra Comique and by a theatrical performance by the members of the Théatre Francais.

Paris, August 7.

Pinard, of Paris, in the Section on Obstetrics, read a paper on the "Puerperium;" Hagapoff, on "Regimen as a Means of Preventing Diseases of Pregnancy;" Bouffe, of Paris, on "Eclampsia Without Albuminuria, Before or After." Mangiagalli read an article on "Treatment by Veratrum. Dvorak discussed "Venesection and Saline Injections." Perret spoke of "Forceps with Parallel Branches." Calderini treated of "Hydatidiform Mole."

Arnaud read a paper on "How Progressive Paralysis Ends." Tachnisch read one on "Syphilis as Cause of Progressive Paralysis;" and Lalanne on "Spontaneous Fracture in Progressive Paralysis."

In the Section on Gynecology, de Ott, of St. Petersburg, treated of "Second Vaginal Method in Conservative Myomectomy;" Gottschalk and Delagenière of "Ligation of Arteries;" Pozzi, on "Limits of Myomectomy," and Tuffier, on "Abdominal Myomectomy."

In the Section on Internal Pathology, Villard treated of "Pneumonia and Bronchopneumonia." Widal, of Paris, had an article on the "Spleen and Its Affections." Papillon read a paper on "Bacteriology of Rheumatic Fever."

Von Bergmann, of Berlin, in the Section of Surgery, stated in a paper on "Radiography in the Study of Fractures and Luxations," that the subject of fractures had made during the last ten years two important steps: 1, the [illegible] treatment of certain simple fractures by [illegible] the fragments, and 2, the diagnosis of the point of fracture and the condition of the bony lesions by means of radioscopy and radiography. Examination of recent patellar fractures shows, with the aid of the Roentgen rays, three obstacles to a complete cure: 1, the inequality of the two fragments; 2, multiple fragments; 3, the two fragments become displaced, with respect to one another, by a movement of rotation. Von Bergmann has obtained in his clinic, with the aid of the X-rays, in more than twenty-five cases of this kind, a complete bony consolidation. Fractures of the bones of tarsus and metatarsus were almost entirely unknown before the invention of radioscopy.

Maunoury, of Chartres, discussed the same subject as Von Bergmann. He said that the radiograph was useful in all fractures, especially those of the ankle. The formation of callus is very interesting to study by means of radiography. The duration of its formation is variable; it appears longer, the thicker the bones. In certain cases, notably in oblique fracture of the tibia, the callus may remain a long time invisible, even when the consolidation is complete. The discovery of Roentgen, though of less utility in luxations than in fractures, will often be found of service.

Championnière, of Bordeaux, followed with a paper on "Massage and Fractures."

In the Section on Therapeutics Kleckowsky read a paper on "Ergotin in Pneumonia," and Ehlers concluded the papers for the day with one on "Treatment of Leprosy by Arsenic and Iron."

Paris, August 8.

In the Section on General Pathology Ewald treated of "Autointoxications;" Claude and Balthazard took up the subject of "Toxicity;" Smeraglia read a paper on "Pathogenesis of Uremia," and Charrin delivered "Remarks on Eclampsia." These papers were discussed by Ewald and Leube. Lenoir read an article on "Extrabuccal Alimentation;" Herard, on "Action of Milk on Gastric Chemistry;" Delbet, on "Pathogeny of Varicose Veins;" Tuffier, on "Pulmonary Surgery;" Guilleminot, on "Technique;" Finsen, on "Phototherapy;" de Schweinitz, Washington, on "Work on Tuberculosis in the United States."

In the Section on Internal Pathology Furster read a paper on "Raw Meat as Treatment for Consumption;" Donahue, of Syracuse, on "Milk of Tuberculous Cows the Chief Danger." The latter reported a large number of communications on the subject. Labodie, of New York, gave a "New Method of Treatment of Consumption," by direct transfusion of drugs into the tubercular spots.

In Pediatrics, Barbier read a paper on "Gravity of Acute Rheumatism in Children and Consequent Heart Affections." Brunon, of Rouen, discussed "Alcoholism Among Children of Normandy."

In Psychiatry, Korsakof, of Moscow, spoke on "Rest in Bed as Treatment of Acute Forms of Folly."

In the Section on Neurology, Ferrier, of London, and Roth, of Moscow, discussed "Diagnosis of Organic and Hysteric Hemiplegia."

Ricard started, on Wednesday, the work in the Section on General Surgery. He was followed by Sorel, of Havre, and Weir, of New York, on "Appendicitis." Ochsner, of Chicago, read a paper on "Elimination of Appendix."

"Radiography in Obstetrics" was discussed by Focher, of Lyons, Varnier, Maygrier and Bouchacourt.

Terrier, in the Section on Gynecology reported "Two Hundred Abdominal Hysterectomies." Clarke, of Boston, read a paper on "Surgical Treatment of Inflammatory Condition of Fallopian Tubes," and A. Palmer Dudley, of New York, read an article on "Conservative Operations on Ovary."

The reception and fête announced to be given by the president of the Republic, at the Palais de l'Elysée on Thursday was not held, but a reception was tendered the members of the Congress by the Municipal Council of Paris in the Salons of the Hôtel de Ville on Saturday afternoon.

The third general session will be held on Thursday for the election of officers and the selection of the place of meeting for the Fourteenth International Medical Congress.

Miscellany.

Typhoid Fever in Paris.—An epidemic of typhoid fever holds sway in Paris. Drs. Thoinot, Martin and Miguel have been investigating the subject, and the water-supply from the River Vanne seems to be the cause. In 1899 the number of cases was 4329, of which 398 were reported in the first ten weeks. During the same period in 1900, 891 cases were reported.

Mortality in India.—The Governor of Bombay reported to the Foreign Office, July 9, that there were 10,320 deaths from cholera and 6502 fatalities in the famine district during the last week in June. The total deaths among the numbers on the relief works in the British district were 5324. The number on the relief works is increasing rapidly in consequence of the drought. The number of those applying for gratuitous relief is increasing throughout the affected districts. The total number of persons receiving relief is 6,013,000.

The Journal Has Largest Circulation.—*Printers' Ink*, otherwise known as the advertiser's "School Teacher," in its issue of August, credits The Journal with the largest circulation of any medical weekly in America. It quotes the weekly average at 14,401 for twelve months ending March 1, 1900. While these figures are correct, they hardly do The Journal justice, as our weekly issue has been gradually increasing, and for the past six weeks the average is over 17,500 copies. This week we are issuing over 17,750.

Congress of Professional Medicine.—"The struggle for existence has become so severe for physicians in all countries, and they are so constantly assailed by a crowd interested in caluminating them, that they have at last felt the need of meeting and talking things over among themselves—what they have always felt, but never dared to speak aloud before." These are the opening words of an editorial in the *Gazette Méd. de Paris*, deploring that the membership of the Congress of Professional Medicine, which convened July 23, was not representative of the majority of practitioners, owing to the systematic and inexplicable holding aloof of many French and foreign physicians. "Every time anything novel is attempted, any effort made to change the old routine, it is like throwing stones into a frog-pond. All the more credit to the men of energy who have initiated the movement and set an example for the world to imitate!"

Railway Accidents.—The official figures given out by the Interstate Commerce Commission for the year ending June 30 show that during this period there were all told the sum of 51,743 casualties resulting from railway accidents. Of this number 7123 persons were killed and 44,620 were injured. The number of trespassers killed and injured was quite large, there being 4040 killed and 4730 injured. The number of admitted passengers killed was 259, and the number injured was 3442. During the previous year there were 221 killed and 2945 wounded. The ratio of those killed to those who traveled was 1 person to every 2,189,023. Of the employees 1 out of every 420 was killed, while 1 out of every 27 was injured. Of the persons working on locomotives 1 was killed to every 165 persons. In New York State, where safety brakes have been employed, there were 260 persons killed as against 279 for 1898, and 6725 injured against 6988 for the previous year.

Presentation of Statuary.—Dr. Paul Richer, of Paris, has presented the Académie des Sciences with a bronze group of three runners, modeled on cinematograph pictures, taken at the Racing Club and elsewhere. They reproduce the three most typical attitudes, and the *Gaz. Méd.* adds that it is amazing to note how perfectly they harmonize with the Greek antiques.

Prizes Offered by Mexican National Academy of Medicine.—A prize of 500 pesos will be awarded for the best original work in Spanish, on either of the following subjects: "Nature of Remittent Fevers Observed in the Mexican Mesa," and "Diagnosis and Treatment of the Different Varieties of Intestinal Occlusion."

Paraffined Waterproof Cloth.—Cathoire announces that all fabrics and garments can be rendered absolutely waterproof by being dipped in a mixture of two parts paraffine—

melting at 52 C.—and one part vaselin dissolved in kerosene—25 gm. to the liter. The expense is about a franc for an entire uniform. He mentions in his communication to the *Revue d'Hygiene*, 1900, p. 296, that one of the most important advantages is the absence of the extra weight of wet garments. The mixture does not interfere with the evaporation from the skin, as the garments thus impregnated showed no traces of moisture on the side toward the body. Pieces of paraffined cloth were sterilized in the oven without injury.

Antimalaria Campaign in Italy.—The mowing, reaping, and plowing of the Pontine Marshes and other extensive tracts in Italy claims hundreds of victims as the laborers flock to these hotbeds of malaria. A campaign has been instituted this year against the infection, and eight ambulances have been sent out by the Red Cross Society to apply preventive and curative measures. The portable shelters for the workmen are to be protected against mosquitos, and also many of the houses of the station agents along the railroads, as the experiences in this line last year were highly instructive. The government also plans to supply the peasants in malarial districts with protections against mosquitoes.

Determination of Sex.—The conclusions of the latest German writers are that the sex is already decided in the ovary, as has been conclusively shown for bees and certain lower forms of life. The only means by which the determination of sex can be influenced is by the nutritional processes in the ovary. Disturbances in the ovary in this line, dating possibly from fetal or infant life, seem to determine a preponderance of male ova, while abundant, normal nutritional processes favor the production of females. Ploss has noted a coincidence between the higher prices of provisions and the larger number of boys born. Schenk, on the other hand, considers the female offspring the evidence of nutritional disturbances, as several mothers of boys gave birth to girls after symptoms of diabetes were first observed, which was the origin of his famous method of sex determination.

New Antituberculous Journal.—We have received the first number of *L'Oeuvre Antituberculeuse*, a quarterly that has been started with a view to arouse interest in the various public and private institutions that have been inaugurated in France in the campaign against tuberculosis. The Hauteville sanatorium is described and illustrated, among others. The three buildings face the south, southeast and east; the triangular spaces between them are filled in with a sheltered and covered piazza open only toward the front of the buildings, which thus enclose a large sheltered space. The Guelpa pocket cuspidor is supplied the patients. The communications assert that a consumptive is more cheerful when with other consumptives than when living at home or with healthy people.

Laveran's New Stain for Malarial Blood.—The new staining process used by Laveran is described in full in the *Comptes Rendus* of the *Soc. de Biologie*, June 9. It is extremely delicate, simple, easy and reliable, and stains the nuclei deep violet; the reds are pink, the protoplasm of the parasites is a pale blue, the chromatin violet red. He has been successful with preparations of dried blood several years old. Three fluids are rerequired: 1, silver oxid methylene blue, or "Borrel blue." This is prepared in a flask of 150 c.c. of distilled water. When the crystals are dissolved, the flask is filled up with a solution of soda and shaken. A black precipitate of silver oxid is deposited, which is washed to free it from traces of azotate and soda. An aqueous saturated solution of medicinal methylene blue is then poured over it and left for seven or eight days, shaking from time to time. No. 2 is an aqueous solution of eosin at 1 per thousand, and No. 3, a 5 per cent. solution of tannin. A bit of camphor in each vial will prevent mold. The specimen of blood dried in a thin layer is fixed with absolute alcohol for about twenty minutes. The stain is mixed just before using, in the proportion of 4 c.c. of the solution of eosin; 6 c. c. of distilled water and 1 c. c. of "Borrel blue." The fluids are filtered separately as they are poured into the graduated test-tube, stirred, and then transferred to a porcelain crucible. The slip holding the blood is placed on top of the fluid, so that the blood rests in the fluid as the slip floats. Five to ten minutes is sufficient to stain the chromatin of most hematozoa, especially that of malaria, but several hours are necessary for the endoglobular parasite of birds. When the stain is deep enough the preparation is rinsed and treated with the solution of tannin for a minute, then rinsed again and dried. If the stain is too intense wash with alcohol before mounting in balsam.

A New Movement for the Organization of Private Asylums.—The Association for the Study and Cure of Inebriety held a meeting June 17, at Greenwich, Conn., for the purpose of securing a thorough organization of all private asylums which treat mental diseases and drug cases. It was claimed that there are nearly a hundred asylums, homes and sanitariums in the New England and Middle states for the treatment of inebriates, mental and nervous cases, over half of them being charlatan in their boasted specific cures and advertised nostrums. Such institutions are without organization or system, and appear and disappear continually. They are without state or local license or supervision, and are managed by unknown persons, and the public is unable to discriminate between them and reputable institutions. They claim exemption from all supervision from the fact that their patients suffer from alcohol, opium, and other drug poisons, which are not recognized as other than moral disorders. There is no restraint to prevent any who desire from opening homes and sanitariums for these cases. In nearly all these states, institutions for the treatment of mental cases with drug habits are licensed and come under the supervision of the authorities, and have some reputation and standing in the community to secure patronage. A large number of representatives of different asylums were present, and the following propositions were agreed upon as representing the objects of this meeting: 1. To promote the scientific study of alcohol, and other drug neuroses, and to encourage desirable and special legislation with reference to the care and control of such cases. 2. To isolate the chronic, pauper inebriate from the insane and criminal class, and secure the erection and maintenance by the several states of institutions for the segregation and special treatment of chronic, pauper inebriates, and to incorporate farm colonies or other forms of institutional relief which shall combine medical care with occupation, control, and discipline. 3. To secure in all states the special supervision and inspection of all institutions for the care and control of inebriates and other drug neuroses. 4. To discourage and prevent all efforts to treat alcoholic inebriety or the opium and the other drug addictions with secret drugs and so-called specifics and to prohibit the sale of all nostrums which claim to be absolute cures and which contain alcohol, opium, or its alkaloids, or other pernicious and harmful drugs, or which contain substances which are inert and are fraudulent impositions on the public. 5. To encourage as an association every individual and organized effort to study scientifically and practically all the various means and methods of both cure and prevention which are found valuable in the treatment of alcohol and other drug addictions. 6. There are many institutions in this country which treat the alcoholic and other forms of drug addiction associated with mental and nervous cases. These institutions should all be organized and follow some general principles and methods of practical work. By this means public opinion could be more effectually influenced and legislation secured, resulting in a great advance in the uniform scientific treatment of these cases. 7. We urge all asylums and institutions to unite with us in an effort to raise the subject of the medical treatment of these borderland cases out of the realm of quackery into that of exact scientific work, and in this way be able to treat these obscure, diseased conditions in a rational way and along rational lines.

These propositions were unanimously indorsed and another meeting was projected in October at Hartford, Conn. The Secretary, Dr. T. D. Crothers, of Hartford, Conn., solicits correspondence from those interested.

Registration of Yellow-Fever Non-Immunes.

Under date July 3, 1900, Major Francis J. Ives, surgeon U. S. Vols., chief surgeon of the Department [illegible]
Santa Clara, Cuba, ca[illegible] owing [illegible]
lished as a precautionary [illegible] inst[illegible]
fever in the Depa[illegible] p[illegible]

The mayors of the following cities, Matanzas, Cardenas, Colon, Cienfuegos, Santa Clara, Trinidad, Sancti Spiritus, Sagua la Grande, Caibarien, Placetas and Remedios should be required at once to prepare a list of all non-immunes, exclusive of the officers and soldiers of the United States Army, but including the families of the above, and all civilian employees. In order to obtain this list a proclamation should be issued by the mayor requiring every non-immune to be registered, stating in each case the full name and address, and whether an adult or a child, all persons over 16 years being considered adults. In this proclamation the necessary measures for securing this information should be embodied. It should be clearly stated that any adult failing to comply and be registered at the end of ten days after the date of the order would be fined at one dollar for every day that he or she remains unregistered, and the parent or guardian of any child will be fined an equal amount for all children not registered, in the same manner, and amount as above.

The term *immune* should be construed to mean all natives of the Island of Cuba, all foreigners who can establish a residence of at least ten years on the island, and all others who can produce a certificate from a reliable physician that they have had yellow fever. The term *non-immune* signifies any person who is not an immune, as above described.

The proclamation should be written in both Spanish and English, and conspicuously posted on the bulletin boards in front of each alcaldia; in addition it should also be advertised in the local papers.

2. Should yellow fever appear in any of the towns in this department to an extent sufficient to create apprehension of its being exported, the chief sanitary officer of the department will notify the mayor of the affected town to permit no non-immune to leave the town without previously notifying the mayor in writing of the date of such departure, and the destination. The mayor, upon being thus notified, will at once notify by telegraph the mayor of the town to which the non-immune is going. The latter mayor will, upon the arrival of the non-immune, ascertain his address, and cause his chief sanitary officer, or one of the municipal physicians, to investigate and keep the case under observation until the period of infection has passed. Should the non-immune be an officer or soldier, the commanding officer of the garrison from which he leaves should be required to notify the commanding officer of the garrison in the town where the non-immune is going, and the military surgeons be required to take the necessary precautions. Should a non-immune of the latter class be going to a town where there is no garrison, the commanding officer will notify the mayor of such town, who will take the same measures as in the case of those not connected with the military establishment. Should any non-immune arrive from an infected town at any of the seaport towns, the quarantine officer of the port should be at once notified of that fact by the local municipal authorities, or by the military authorities in case of an officer or soldier or a member of the family of an officer or soldier.

There should likewise be a punishment for all non-immunes failing to give the proper notifications to the municipal authorities, consisting of appropriate fines or imprisonment, or both.

Societies.

Coming Meetings.

American Academy of Railway Surgeons, St. Paul, Minn., Sept. 5-6.

American Association of Obstetricians and Gynecologists, Louisville, Ky., Sept. 18-20.

American Electro-Therapeutic Association, New York, N. Y., Sept. 25-27.

Medical Society of the State of Pennsylvania, Wilkesbarre, Sept. 18.

Bucks County (Penn.) Medical Society.—This Society held its midsummer meeting in Bristol, August 1.

Lehigh (Pa.) Medical Association.—The twelfth annual conversational meeting of this Association was held in Allentown on July 25. Among those present were Dr. John B. Roberts and Dr. Boardman Reed, of Philadelphia. The next meeting will be held in Reading.

Bar Harbor (Me.) Hospital Club.—The annual meeting of this Club was held on Wednesday, July 11, 1900. Dr. John B. Shober, Philadelphia, was elected president; Dr. E. J. Morrison, Bar Harbor, secretary and treasurer, and Dr. H. D. Averill, Bar Harbor, executive officer for the ensuing year.

Rock River Valley Medical Association.—This Association met in Dixon, Ill., July 25. The following officers were elected for the ensuing year: president, George Proctor, Coleta; vice-president, C. M. Cheadle, Lee Center; secretary, C. S. Murphy, Dixon. The next meeting will be held in Polo, December 26.

Southwestern Iowa Medical Association.—This Association will meet at Glenwood, August 16. Dr. J. A. Rawls will deliver the presidential address. Papers will be read by Drs. M. B. Reed, Charles E. Stevenson, F. B. Dorsey, B. F. Gillmor, J. P. Lord, C. B. Powell, B. N. Torrey, J. W. Reynolds, M. N. Voldeng, B. L. Eiker, Arnold Jolly, D. Macrea, Jr.

The Canadian Medical Association will meet in Ottawa, September 12, 13, and 14. It is announced that, in addition to Mr. Edmund Owen, of London, Eng., Dr. F. Shattuck, Professor of Clinical Medicine in Harvard, will address the meeting. It is also expected that Drs. Nicholas Senn, of Chicago; Allen McLane Hamilton, and A. G. Gerster, of New York, will be present. The address on "Gynecology" will be delivered by Dr. William Gardner, of Montreal.

Southern Minnesota Medical Association.—This Association held its annual meeting in Winona, August 1. The following officers were elected: president, E. D. Keyes, Winona; first vice-president, A. I. Baker, Byron; second vice-president, J. W. Scott, St. Charles; secretary and treasurer, W. T. Adams, Elgin. The secretary's report showed the society to be in a flourishing condition, having doubled its membership in the past two years.

San Francisco County Medical Society.

San Francisco, Cal., July 10.

President Dr. E. E. Kelly in the chair.

PREVENTION OF PULMONARY TUBERCULOSIS.

Dr. W. N. Sullivan presented a paper on this subject. He said that prophylaxis of tuberculosis includes the care of the individual predisposed to consumption, and embraces those general measures for the restriction of the dissemination of the bacilli among communities. The individual predisposed to the disease should be placed under auspices which will favor healthy development, such as correction of anemia, improvement of appetite and digestion, and proper hygienic treatment out of doors. Mouth-breathing should be corrected by removing obstructions in the nasopharyngeal tract. He advocated breathing exercises and the chest-weight machine as valuable measures in the development of the chest. The bicycle, by bringing the individual into the open air, has a distinctly beneficial effect. When tonics are necessary, he thinks that cod-liver oil and iron preparations would find their place in aiding the constitution to resist tuberculosis. He urged the necessity for a proper receptacle for sanitary disposition of the sputa, and recommended the use of the sanitary cuspidor constructed by Dr. Dettweiler, and modified by Dr. Knopf. All articles and utensils used by tuberculous patients in eating should receive the greatest care to prevent the infection of others. Public prophylaxis offers a field for work of the greatest usefulness. Institutions where large numbers of people are congregated, schools, prisons, insane asylums, workshops and factories, should have a close supervision with a view to limiting tuberculosis. The disinfection of rooms occupied by tuberculous patients should be made not only after their death, but should be carried out at frequent intervals during life. Much good has been done in the prevention of tuberculosis by societies formed for the purpose of distributing literature on the subject and giving lectures at intervals for the education of the masses in this respect. He thought that bovine tuberculosis is regarded as one of the chief sources for the infection of man, for the reason that milk, butter and meat constitute the most important and universally used articles of food, and considered that in the war against tuberculosis efforts should be divided equally between the bacilli that are ingested and the bacilli that are inhaled.

EARLY RECOGNITION OF TUBERCULOSIS.

Dr. Clark J. Burnham detailed the well-known signs of early tuberculosis, such as clubbed fingers, emaciation, the capricious appetite, and cog-wheel respiration, which he considers of very qualified value, for they may be due to other causes; whereas the tenderness on percussion over the apex of the lung, lessened movement of the chest wall, abnormally clear percussion-note, broncho-vesicular breathing, relative and absolute intensity of the heart-sounds over the affected apex, and accentuation of the pulmonary sounds, are signs of more value. He considered family history a very important factor in interpreting the value of these signs and symptoms, but a history of exposure to tuberculous contagion more important. Pronounced anemia, without apparent cause, early menstruation, dyspnea and pain in the thorax made worse by exercise, abnormal dwarfishness—not under weight, but a lack of symmetry and development—dyspepsia, intermittent albuminuria, and slight attacks of hemoptysis, produced by hyperemia, are apt to occur during the early stages. An early diagnosis, however, is not easily arrived at. The tubercle bacillus appears in the sputum at a comparatively late date. The general and local symptoms mentioned do not offer absolute certainty so long as no bacilli are detected, hence any additional diagnostic signs must be of considerable value if they are decisive and involve no danger to the patient. He considered the tuberculin test as one of the surest, as it gave positive reactions in 72 per cent. of more than 2000 suspected cases. There is no danger of rendering a patient tuberculous who is not already so, inasmuch as in tuberculin a bacterial toxin, and not an attenuated virus is used. The only possible risk is the aggravation of pre-existing symptoms as a result of the reaction in more advanced cases of phthisis. A sign of certain diagnostic value, he thought, was the one recently called to the attention of the profession by Dr. Thomas F. Harrington, Lowell, Mass., namely, the dilated state of the pupils. He urged the necessity of making careful and frequent examinations of the sputum, in the search for the bacillus tuberculosis.

TREATMENT OF TUBERCULOSIS.

Dr. George W. Fuller dwelt at considerable length on the prophylactic treatment. He thought that great care should be taken regarding the right kinds of food for these patients, and that specific amounts should be taken at particular intervals, care being taken not to give too large a quantity at first. When digestion is weak, he frequently orders some medicinal aid, resorting to any and all reasonable measures within his power to supply the system with nourishment. He favors the morning bath, given with warm or tepid water, the temperature being gradually decreased according to the patient's strength, until it can be taken cold. At night a light sponge-bath of tepid water and alcohol, equal parts, is often refreshing. As the patient gains strength he advocates swimming, in salt water, if possible. He thought that if there was a specific for the cure of consumption, it was fresh air, and the patient must be taught how he can best get it into his lungs, and therefore advocated breathing exercises as the most essential part in the whole treatment of pulmonary consumption. The author's experience regarding specific treatment was too limited to express an opinion for or against its efficacy. Two of the most valuable remedies for the treatment of this disease he had found to be iron and arsenic. Strychnin and quinin are also of value. Phosphorus is a remedy that is often forgotten in the treatment of tuberculosis; it stimulates the brain and circulation, the functions of the stomach, and aids digestion. He thought that chloroform stood at the head of the list of drugs for inhalation, the objection to it being the difficulty of its safe administration. It is his opinion that if, in the future, a drug or medicine will be found that will have a specific action upon pulmonary tuberculosis, that remedy will be administered by inhalation.

Second District Branch of the New York State Medical Association.

Held at Schenectady, June 28, 1900.

President, Dr. E. D. Ferguson, of Troy, in the chair.

THE PRESENT STATUS OF THE STATE ASSOCIATION.

This was the topic of the President's Address. He said that in 1884 the New York Medical Association was organized. The reason for its organization was the fact that the State Society had modified its Code of Ethics, and had placed itself outside of the pale of fellowship with The American Medical Association. The Code of Ethics is part of the organic law of the latter association, and up till 1883 was part of the organic law of the state society. At that time the alternative had presented itself of forming a new state organization or allowing the State of New York to be without representation in The American Medical Association. The result was the establishment of the New York State Medical Association. The law of The American Medical Association is that any one can become a permanent member through the subordinate state organization, but in order to retain their permanent membership they must continue their membership in the affiliated or subordinate body. Recently there had been a disposition to enforce that regulation, and consequently a good many men had been inquiring how they might become members of The American Medical Association.

Last winter the New York State Medical Association secured from the New York State Legislature a charter, and, so far as the legal representation is concerned, the New York State Medical Association stands on a par with any other similar organization either within or without this state. This charter requires a reorganization of the State Association, and this power was given to the Council of that Association. The Council had met and re-elected all of the officers of the association. The proposed plan of organization was to organize throughout the state county organizations, to be in affiliation with the State Association. Whenever there are ten members in a county in sympathy with the State Association they are to form a subordinate county association, elect their officers, and increase their membership as they deem fit. These members will be likewise members of the State Medical Association, for, membership in the one carries with it membership in the other. Already the New York County Medical Association and the Kings County Medical Association had unanimously resolved to become subordinate counties of the reorganized State Medical Association, thus bringing the membership in the State Association at one jump up to 1200 or 1400. In May last the Erie County Medical Association was organized, and last winter the Genesee County Association voted to become a county association in affiliation with the State Association. Up to July 1 of this year all who join the New York State Medical Association are charter members. The committee on by-laws is now preparing the by-laws, a copy of which would be sent to every member throughout the state for careful and deliberate consideration before action is taken thereon.

The speaker then urged those present to become members of The American Medical Association, pointing out the great value of The Journal, which, in itself, was well worth the sum paid for annual dues. A large membership, he said, in the national body was important, because of matters of importance in legislation which were constantly demanding the attention and exertions of a united medical profession, for example, the movement against vivisection, and the proposed national department of health.

Dr. George E. McDonald, in a few happy and well-chosen words, welcomed the branch association to Schenectady.

NEW INSTRUMENTS.

Dr. Ferguson then presented a new director, which he had found useful in connection with vaginal hysterectomy. The object of the instrument was to isolate the broad ligament completely and at once, on one side. After separating the peritoneum and tissues in front of the uterus, the curved director is passed around the broad ligament, and the latter is then quilted off.

Another instrument presented by him was a pair of forceps for lifting up the uterus in the operation of ventral suspension. In many stout patients, those who take the anesthetic badly, and in cases having many adhesions, the suturing of the uterus to the abdominal wall was not always easy of accomplishment. One blade of these long, slender forceps is passed behind, the other in front of, the uterus, and the blades are locked, just as is done with the obstetric forceps.

SOME REMARKS ON THE SO-CALLED WIDAL'S REACTION.

Dr. William Finder, Troy, said that Peffer had been the first to point out that serum might be introduced into animals which contained an antitoxin, and which produced immunizing effects. He pointed out that the toxin of the typhoid bacillus exists principally in the body of the bacteria, and is not demonstrable in the filtrate of a recent culture-fluid. He also pointed out that these antitoxins are very unstable. The serum of animals immunized with such a toxin contains antitoxins which possess a specific action against the typhoid bacillus, but have no such action on the colon or other bacilli. The great practical diagnostic value of the serum reaction was, however, first demonstrated by Widal. It was the part of prudence in performing this test to make sure that the typhoid bacilli of the culture-fluid are at the time in active motion, and that the dilution is at least one in ten. The test can be made with a microscope having only a magnifying power of 400 diameters, though it is much more evident when an objective giving nearly double this magnification is employed. Frankel, after an experience with two epidemics, believes the "hanging drop" the most rapid and accurate diagnostic method for use in connection with cases of typhoid fever.

The author then reviewed the literature at length. He said that Drs. H. M. Biggs and W. H. Park, of New York, had examined 200 cases. Of the 140 in which the final diagnosis was typhoid fever, the reaction was obtained in 100, and of the 57 in which the final diagnosis was other than typhoid there were 57 negative results. These observers claim that a positive diagnosis can be made from the Widal reaction in 50 per cent., and a probable diagnosis in about half of the remainder. J. M. Anders and McFarlane had reported on 250 soldiers supposed to have typhoid fever, in whom the Widal test had been made. Of this number, 219 gave a positive reaction, and 10 gave no reaction though tested repeatedly up to the time the temperature became normal. Of the 219 positive reactions, 128 were obtained before the appearance of the roseola; in 8 no reaction was obtained as late as the twenty-eighth day. In 2 the reaction was not obtained up to that time. The authors' conclusions were: 1. The agglutination is a phenomenon of infection which may be present in the very first days of the disease, and may not be demonstrable until toward the end of the first or second week of the disease, and in some very rare cases, has been absent. 2. It is a vital reaction of the microbe. 3. A negative reaction furnishes a probability that typhoid fever does not exist, but the positiveness of its non-existence should not be based on one test or on tests made a few days apart, but upon the examination of the case every other day up to the time of normal temperature. 4. A positive reaction obtained by the rules laid down should be considered a certain sign of typhoid fever.

Dr. H. C. Gordinier, Troy, said that during the past year three cases had come under his observation showing the great value of this diagnostic test. Two of the cases were acute tuberculosis, and one was a case of typhoidal pleurisy. The first case had come into the Good Samaritan Hospital in the second week of the illness, but several examinations for the Widal reaction had been negative. The whole course of the disease thereafter had been typical of acute miliary tuberculosis up to the time of death, but no autopsy had been obtained. The second case was seen in private consultation practice. This man gave a history of an undoubted typhoid fever three years before. No positive diagnosis had been made at that time. When seen about ten days later, there was great dyspnea, and a well-marked effusion on the right side of the pleural cavity. This contained an active motile bacterium, which was identified at the Bender Laboratory as the typhoid bacillus. The third case was one of acute miliary tuberculosis. He had first seen the patient with an enlarged spleen, tympanitic abdomen, and a temperature of 101 F., but no eruption. The temperature rose somewhat higher, but never excessively, and at no time did it resemble the typical range of typhoid temperature. Examination of the chest was absolutely negative. The Widal reaction was absolutely negative. Other physicians saw the patient, but no positive diagnosis had been made. After he had been ill about three months, he had developed the characteristic symptoms of an acute miliary tuberculosis. The case ended with symptoms of meningitis and death.

BLOOD EXAMINATIONS IN THE DIAGNOSIS OF TRICHINOSIS.

Dr. H. C. Gordinier made some interesting remarks on this subject, reporting illustrative cases.

Dr. William Finder said that these cases only emphasized in a very significant way the great value of blood examinations in disease in general. It was remarkable how one could differentiate between acute rheumatism and la grippe by one simple examination of the blood.

Dr. J. T. Wheeler, Chatham, said that this blood test for trichinosis was of exceptional value because before it was known the only other test available was one which could not often be applied in private practice. Comparatively few patients would consent to the removal of a piece of muscle with the harpoon.

Dr. J. C. Hannan said that while deeply interested in this new means of diagnosis, he was disappointed at not hearing of some efficient method of treating these cases.

Dr. Ferguson said that a piece of muscle could be easily secured at the present time with the aid of local anesthesia by the Schleich method, using a small quantity of a 1 per cent. solution of cocain. The harpoon method did not give a sufficiently large specimen of muscle.

Dr. Gordinier remarked that of the 21 cases reported since 1897, the diagnosis had been made in all by examination of the blood.

DEPRESSED FRACTURE OF THE LEFT FRONTAL BONE, WITH SYMPTOMS SHOWING DISSOCIATION OF MOTOR SPEECH FROM WRITING CENTER.

Dr. H. C. Gordinier made this report. He said it had been supposed by physiologists that there was a writing center. His former case had been trephined by Dr. Ferguson, but her condition had been so bad that the operation had been hastily terminated. She had died a few days later, and the autopsy showed the lesion to be at the base of the second left frontal convolution, and nowhere else. It was absolutely separated by a sulcus from the motor area of the brain. A careful histologic study of the brain had proved that it involved no other area. The only localizing symptom was loss of the power to write. Recently he had seen at the Good Samaritan Hospital a boy who had fractured the left frontal bone. Trephining had been done, and shortly afterward a considerable hematoma had formed, as shown by complete motor aphasia and paralysis of the right side of the face and slight weakness of the arm on that side. He had tested the patient, a boy of 13 years, three days after operation, and had found that his ability to write was not impaired, though he could not speak. Later on the boy had been able to say single words. This case did not prove the position of the writing center, but went far to show that such a center exists separate from the motor speech center. A photograph was presented showing the position of the fracture.

Dr. E. D. Ferguson said that the boy had been kicked by a horse just above the supraorbital ridge, extensively fracturing the bone, a portion of which was driven into the brain. He had removed the loose fragments, but from the condition of the wound he did not feel justified in closing the dura mater. Drainage was employed, and quite naturally a very large hernia cerebri had developed. Nothing had been done for the latter, and in time it had entirely receded into the cranial cavity. The boy seemed to be in very good mental condition. Dr. Ferguson said that some years ago he had seen a woman presenting the symptoms of embolism, and more or less motor disturbance, with absolute word-blindness. She could converse as well as ever, though printed words were absolutely without significance to her.

Dr. George F. Comstock, Saratoga Springs, presented a very perfect specimen of extrauterine pregnancy which he had recently successfully removed.

UTERUS BICORNIS.

Dr. E. D. Ferguson reported a case on which he had operated the day before for what had been supposed to be a chronic appendicitis and a retroversion of the uterus. After having removed the appendix he had found what appeared to be a band of adhesion running from the mesocolon across Douglas' pouch to the base of the bladder. Careful search showed that he was dealing with a U-shaped uterus bicornis. The woman had borne two children, and both uteri were retroverted.

THE RADICAL CURE OF HYDROCELE.

Dr. Crawford E. Fritts, of Hudson, presented this paper, which will be published in a future issue of The Journal.

Dr. William Finder supplemented the paper with some remarks founded on his own experience. In one case, under cocain anesthesia, he had made an incision and stitched back the tunica vaginalis, but the case had relapsed. The operation had been repeated twice since then, with the same result. He had then tried the method known as Wincklemann's. The scrotum is incised and the tunica vaginalis is separated from all adhesions. It is then opened, and the fluid evacuated. The tunica vaginalis is turned inside out, and finally the testicle and the distorted tunic are returned to the scrotum and sewed up. The wound healed by primary union, and in a week's time the man had returned to his work. There had been no relapse or other discomforts. In this case he had used a 5 per cent. solution of cocain, yet there had been no symptoms of poisoning.

Dr. Ferguson said that the bichlorid method was a novel one to him. Personally, he had always used the injection of iodin, adjusting the quantity somewhat to the capacity of the sac. So far as he knew there had been no failures. The use of the iodin he believed had not been responsible for the occasional occurrence of gangrene. One of his earliest surgical experiences had been the tapping of a hydrocele in an old man. This had been followed by gangrene and sloughing, but the man had ultimately recovered, and his hydrocele had remained cured. He believed it was not the iodin that caused the mischief, but the infection introduced by the surgeon. The results described in the paper were so exceedingly good that he felt disposed to try it. He thought it might be an advantage to dissolve the bichlorid of mercury in normal salt solution instead of in pure water. Some weeks ago he had seen a case in which a seton had been used for the radical cure of a hydrocele. The scrotum was much swollen on the affected side, and with the aspirator he had withdrawn a moderate amount of serum. He had been inclined to think that the bulkiness of the scrotum was largely owing to the presence of an omental hernia. The man had subsequently submitted to operation, and the correctness of this diagnosis had been amply verified.

Dr. George E. McDonald, Schenectady, said that he had operated a number of times by the old method, and, so far as he knew, with invariable success. In the last case he had left the fluid in and had simply injected a dram of iodin. The result in this, as in the other cases, had been a complete cure. He had treated a very large number of cases in this way.

IMPLANTATION OF URETER INTO THE BLADDER.

Dr. E. D. Ferguson spoke on the surgery of the ureters, reporting the following case: A woman had been delivered of her first child, and this had been followed by puerperal septicemia and pelvic abscess. The result had been destruction of the ureter and the formation of a uretero-vaginal fistula. After some weeks the case had come under his observation, and he had found the fistula to be located to the left side of the uterus at the line of the broad ligament fold. The ureteral sound could be passed up to the kidney and into the bladder, but it had been absolutely impossible to enter the ureteral opening on that side through the bladder. The fistula being so close to the bladder wall, he had felt justified in attempting to denude the tissues at that point. He had accordingly done a preliminary operation as for closing a vesicovaginal fistula, but the operation had failed. After an interval of two weeks he had passed a sound into the ureter, and dissected away about one inch of the ureter through the broad ligament. He had then formed a vesicovaginal fistula, and had approximated the vesical walls laterally so as to allow the ureter to lie freely in the bladder. The patient was put to bed and the implantation of the ureter was found to have been successful. It was now nearly three weeks since the operation, and the chances were that the remaining vesicovaginal fistula, being the result of operative interference, would close within a few weeks. This operation of implantation, the speaker said, was not very difficult in ordinary cases, and was an operation quite generally accepted at the present time. If the ureter could not be made to readily reach the bladder, a simple dissection would liberate the bladder anteriorly, and allow it to drop back a little, thus giving the operator an additional inch or two. The ureter could be handled quite freely with safety if no sharp instruments were used. The ureter could be conveniently seized and controlled by means of small alligator forceps, one blade of which protrudes beyond the other, and so easily enters the ureter. These forceps were invented by Dr. Kelly.

Dr. John T. Wheeler, of Chatham, was elected president, and Dr. J. E. Baynes, of Troy, secretary, for the ensuing year.

AMERICAN.

1. **Acromegaly and Giantism.**—From the facts of morphology, embryology, and pathology, Hutchinson concludes that the pituitary glands, third ventricle, and pineal tracts are the vestiges of the primitive mouth and gullet, around which the entire mass of the cerebral nervous system is arranged. He thinks that this throws a light over the fact of the pituitary body being a guiding center over growth, and says that if he were to be asked to locate the growth center of the entire body on embryonic and morphologic grounds, he would unhesitatingly select this region. The conclusions at which he arrived are as follow: 1. That the pituitary body is still functional. 2. That disturbances of its metabolism are the principal factors in both acromegaly and giantism, the difference between the results being simply due to the stage of individual development at which the disturbance of the function begins. 3. That the nature of the overgrowth in both these diseases is primarily on the order of a pure functional hypertrophy; later, however, losing some of the definiteness of its impulse, and either producing immature tissue of a mixed type or resulting in simple hemorrhagic exudation, with either cyst formation or complete breaking down of the tissue mass. 4. That it seems probable, although upon this head the evidence is still uncertain, that some part is played by this body in "dwarfism," rickets, and the dwarf forms of cretinism. 5. That a reflex disturbance of its function may possibly underlie the dystrophy accompanying pharyngeal adenoids. 6. That it would appear to be a sort of "growth center," or proportion-regulator of the entire appendicular skeleton.

5. **Neurasthenia and Syphilis.**—Kiernan calls attention to syphilitic neurasthenia as aggravating the infection when it occurs and as embarrassing treatment. He recommends gold as an alterative in these cases, as it has some advantages over other medication.

7. **Chorio-Epithelioma Malignum.**—The case reported was one that was examined in the pathologic institute of the University of Zurich. Talmey believes that it corresponds to those already recorded. The plasmodial syncytial masses are always characterized by three points: Absence of cell outline; deeply stained nuclei; and vacuolation. The numerous fibrous masses are, he thinks, due to coagulation in a late stage of the process.

10. **Amenorrhea.**—Dunning reviews the various causes of amenorrhea: Atrophy of organs; chlorosis; retarded growth; atresia; imperfect development of uterus and ovaries, which he thinks is not uncommon; atresia of cervix; inflammatory lesions; etc. The treatment is discussed in detail, but nothing especially novel is offered.

11. **Location of the Cardia.**—The variety of statements of anatomists as to the exact position of the cardia in the stomach is pointed out by McCaskey, who has devised an instrument consisting of a graduated rubber tube attached to a rubber bulb, and with a very small bag of thin rubber at its other end for its determination. It is introduced into the stomach, and can be inflated as much as desired by pressing the rubber bulb. With this he is able to measure the exact distance from the mouth to the cardiac orifice, reading it on the graduated tube. The information thus obtained has been of very great value to him in a number of cases, as regards both diagnosis and treatment. In certain anomalous cases it is also possible to gain by this means some information regarding the caliber of the upper portion of the stomach.

12. **Decussation of the Nerve-Fibers.**—Smith explains the decussation of the nerve-fibers in the medulla by assuming that the fibers that pass down on the same side act as inhibitory and the others as contracting fibers, so that the fibers proceeding from each half of the brain pass to muscles on both sides of the body and act in concert in controlling the muscles on one side, and simultaneously relaxing them on the opposite side.

14. **Gastric Peristalsis.**—A new apparatus for determining the volume of the stomach and contracting powers of the muscle cells is described in detail by Quinan, with the method of using it, and a case is reported in which it has been employed.

15. **Consanguineous Marriages.**—Irwell thinks from his study that consanguineous marriages are in a great majority of cases undesirable, not because they originate disease, but because they intensify existing disorders or diatheses. It is impossible at the present time to insure that a family is without some taint, and as we are constantly counteracting the process of natural selection, such marriages become more and dangerous. They should therefore be discouraged. Consanguineous marriages should not be thought of in families in which idiocy, insanity, epilepsy, congenital deaf-mutism, hare-lip, cleft-palate, or the phthisical or lithemic diathesis exist, as they may be handed down from one generation to another. It is not, however, essential that identical symptoms or identical diseases be repeated, as transmutation of pathologic conditions is a matter of every-day observation. As there seems to be a proclivity to cancer, it should also be a bar, and he would urge that marriages of persons whose environments have been similar are injurious to the race, and that extreme exclusiveness in marriage is not commendable. If the diseased and degenerate insist on getting married, it is their duty to consider the next generation, and mitigate their innate unfitness by the selection of suitable consorts. He says, let the feeble marry the robust, the neurotic the level-headed, but he does not advise the robust or level-headed to marry the feeble.

16. **Bacillus Aerogenes Capsulatus.**—Welch first notices the history and points out the identity of his bacillus with that of Fraenkel. Its gas-producing properties and the points distinguishing it from the bacillus of malignant edema are noticed at length. The conditions in which it is found in the human subjects are mentioned, and he says that he knows of no organism that has offered such difficulty in determining whether its effects on the human body have been produced before or after death. It is found that it may exist in the living blood, but in the great majority of instances in which gas bubbles are found in the blood and internal organs, the evidence is in support of the view that it is a post-mortem phenomenon. The great importance, however, of this gas bacillus lies in its production of emphysematous gangrene, and this subject is discussed at considerable length. We can not follow all the author says here, and the reader is referred to the paper itself for this as well as for remarks in regard to uterine infections and infections of the gastrointestinal tract. The article is a very valuable and interesting one, and comparatively exhaustive on its subject.

17. **The Function of the State Medical Examining Board.**—Memminger thinks that the examining boards should accept junior certificates as evidence of proficiency and limit their examinations largely to practical questions of medicine. He thinks that this would not lower the scale of medical education, but would tend to elevate and increase practical teaching and produce a better class of medical men.

23. **Headache from Eye-Strain.**—In 1892 [illegible] Wood endeavored to point out that h[illegible] could be distinguished from other fo[illegible] the different types of heada[illegible] ocul

weakness or defects. He excludes, however, all forms of discomfort that find expression in the lids, eyeballs or contents of the orbit. The most important, and perhaps the most obscure, type is that due to incomplete or unsatisfactory muscular effort. The commonest example is supraorbital headache, frequently met with in ciliary strain. He traces the reflex arc back to the ocular motor nucleus and adjacent trigeminus nucleus, from which it is reflected to the terminations of the fifth nerve. He thinks that the proportion of this element is large, and that 40 per cent. is within limits, while 80 per cent. of all frontal headaches are connected with troubles, generally functional, of the eyes. As to the site of headache, we have in order of their frequency: 1, supraorbital; 2, deep orbital; 3, fronto-occipital; 4, temporal. All sorts of combinations and variations of these, however, will be observed. He describes the symptoms. Pain is apt to be dull rather than neuralgic. The eye itself may appear to be perfectly healthy, but astigmatism is probably the most frequent cause, and its determination is of importance in the diagnosis. Weakness of the external eye muscles may be to some extent the cause of ocular headache, how much he does not pretend to say. The headaches that simulate ocular headaches are those connected with supranasal disease, supraorbital malarial neuralgia, certain forms of nervous headaches in neurotic men and women, and a class of incurable headaches associated with organic disease in connection with eye-strain, such as those connected with iritis, glaucoma, etc. The treatment depends largely on the removal of the causes. The cause of nervous irritation must be attended to, whether it be insomnia or dyspepsia, which is one of the most common causes, ocular defects of any sort, and troubles which may be commonly associated in women. As far as local applications are concerned, the simplest is the use of very hot or cold fomentation; the latter is likely to be the most grateful. He says to take a medium sized towel, fold it 12 inches long by 4 wide, dip it into a basin of cold—40 F.—or hot—160-180 F.—water; bend over the basin, pressing the dripping towel gently against the closed eyes, forehead and temples; change frequently and continue the application for five or ten minutes, stopping when it causes pain or discomfort. Do this every hour or oftener while the headache lasts. In conjunction with this he thinks the mixture of equal parts of spirits of lavender, alcohol and spirits of camphor, may be rubbed over the forehead and temples.

24. **Face Presentations.**—McLean speaks of the unfortunate accidents which may be due to face presentations and the difficulty of meeting them, and criticizes the text-books that say they will as a rule, be self-corrected in the progress of labor. The method which he believes most effective is thus described: The patient being under full chloroform anesthesia, the hand is passed carefully into the vulva, with the outside hand seizing the body of the child. In the entire absence of uterine contraction, the chest is pushed as much away from the pelvic brim as possible from the point toward which the chin is pointing in the direction of the occiput, that is, pushing obliquely from behind forward. At the same time the fingers of the vaginal hand are pushed up alongside the head in one or other of the oblique diameters of the pelvis, so that they can reach the suboccipital portion of the head. The thumb at the moment steadies the brow, and with a slight lifting motion imparted to the whole head, it is caused to rotate on its axis as described, the chin passing upward above the sacro-ischiatic notch as the occiput is drawn down below the pubis. Flexion may be considerably hastened by pressing down the occiput by the outside hand as soon as the face is dislodged from its wrong position. He reports cases in which this method was satisfactorily employed.

25. **Trional Intoxication.**—Coleman believes that trional is one of the safest and most efficient hypnotics we possess and has yet to see a really dangerous symptom follow its administration. In one instance he saw a case of trional poisoning, in which a woman had taken 9 drams in seventy-two hours. The patient was in a somnolent condition for some days, and somewhat ataxic and thick in speech. A large dose of saline relieved the symptoms. His statement does not apply, of course, to those cases where it has been used a long period, but he thinks that the case shows that the medicine does not have a depressing effect nor necessarily produce fatal or even alarming results.

30. **Conduction Aphasia.**—Pershing reports a case which he thinks illustrates the conduction aphasia of Wernicke and where there was found a spot of softening immediately above the fissure of Sylvius, 6 cm. back of the junction of its vertical and horizontal branches, and the dorsal half of the right cerebellar hemisphere was destroyed by softening. In this case motor aphasia was excluded by the large number of words correctly uttered; visual aphasia was excluded by the absence of hemianopsia and the large number of words read aloud correctly or otherwise. The case was one of auditory aphasia, but differentiated from other forms by the rapid disappearance of word-deafness without any change in the paraphasia, paralexia, and agraphia. The lesion was small and well defined and, according to the latest views, was so situated as to interrupt communication between the first temporal and third frontal convolutions.

35. **Islands of Langerhans of the Pancreas.**—In 1869 Langerhans published a description of certain bodies consisting of groups of irregular polygonal cells in the pancreas, the nature of which he was unable to determine. Kühne and Lea have described, in injected specimens, glomerular structures composed of dilated and tortuous capillaries which correspond in site with these islands, so-called, of Langerhans. Various conjectures have been made as to their function, that they furnish an internal secretion, etc. Lewaschew claimed that he was able to increase their number at the expense of the acinar tissue by repeated over-stimulation of the gland with pilocarpin or by continued over-feeding. In the human pancreas the interacinar islets are more abundant in the splenic end than elsewhere—three and one-half times as abundant as in the body and head of the organ. In acute inflammatory conditions, the various elements of the gland are almost simultaneously affected, but in chronic inflammations, the islands of Langerhans do not always show alterations corresponding to those occurring in the secreting tissue around them. In some sclerotic inflammations of the organ they seem to be little affected, and Opie distinguishes two types of interstitial inflammation of the pancreas: one which he calls interlobular, which brings out strongly the lobules of the gland with wide bands of sclerotic tissue separating them, the other, the interacinar, characterized by the presence of new interstitial tissue within the lobule. In the first-named, the islands of Langerhans persist unaltered, which he thinks possibly due to the very great vascularity of the parts. They are not affected in obstructive disorder to the organ, and as the ducts do not penetrate through them, micro-organisms reaching the gland by this route would not enter them. In the second form, which he has observed in only three cases, these bodies were generally affected. There is a proliferation of the interstitial tissue forming coarse strands between the columns of the cells. The cells become diminished in size and their nuclei are small and stain deeply. In one peculiar case he found these glands almost entirely destroyed and rendered indistinguishable by hyalin degeneration which was principally associated with these parts. The connection of lesions of the pancreas with diabetes is always of interest, and the relation of these islands of Langerhans to the disorder is especially discussed. In all the four cases of pancreatic diabetes which he has met with, they were more or less affected. In one, which was of the interlobular type, the sclerosis was far advanced. In two out of three instances of the interacinar type, diabetes was present, and in the third case the lesion was accompanied by a condition of general pigmentation known as hemochromatosis. In fact the condition is the bronzed diabetes of French writers, so-called on account of the dark color of the skin. In this particular instance the patient was carried off by typhoid before the lesion of pancreatitis had advanced enough to produce glycosuria. In the fourth case that was mentioned, the condition was accompanied with hyalin change.

36. **Influence of Defibrination on the Kidney.**—Pfaff and Vejux-Tyrode have experimented to improve if possible the technique and method of artificial circulation in the isolated kidney. They found that with the use of defibrinated blood the secretion of the kidney was greatly reduced and contained

albumin, blood and kidney debris, that is to say, the kidney had lost its normal function. When, however, the normal blood from a second animal was used, the kidneys resumed their function, and the pathologic products disappeared, thus proving that defibrinated blood caused a stoppage of secretion in the kidney or produced in the secreted fluid the chemical and microscopical appearances of the urine of Bright's disease. Whether the results of these experiments will throw any light on the cause of Bright's disease can be determined only by further investigations which the authors promise to attempt.

37. **Human and Other Mammalian Blood.**—The distinction between human blood and that of other mammals has been based upon the size of the red corpuscles, and it has been found that they have not been altogether reliable. A new method proposed by Walker is based first on the morphologic and microchemic characters of the granules of the polymorphonuclear leucocytes, and second, on the ability to recognize these conditions in the dried blood. It is well known that leucocytes of the human blood contain granules that are brought out by special staining methods. Disregarding the "mast-cells" these granules are of two kinds, differing in size and staining properties. About 97 per cent. of the polymorphonuclear leucocytes contain numerous, minute, irregular granules which stain in neither basic nor acid stain, but only with certain combination stains like Ehrlich's "triacid," and are therefore called neutrophile. The remaining 3 per cent. contain large spherical uniform granules that stain only with the acid stains—acidophile. Of the other mammals, apes are said to show neutrophiles, but all other species contain only acidophiles and non-granuliferous leucocytes. He describes the condition in different animals and gives a table showing the staining reactions of the granules in a number of species.

39. **Methods of Staining Flagella.**—The method recommended by Robey is summarized by him as follows: 1. Clean cover-glasses thoroughly. 2. Prepare and dry cover-glasses on a level table. 3. Fix in a water bath at 60 C. for one-half hour. 4. Place in Pitfield mordant cold for twenty-four hours or three minutes hot; wash thoroughly in running water and dry. 5. Use the Pitfield stain the same as mordant. 6. Mount in balsam.

41.—See abstract in The Journal, xxxiv, p. 1487.

44. **Rectal Alimentation.**—This is indicated as follows: 1. In conditions in which the passage of fluids from the mouth to the stomach or to the small intestine is impeded or made impossible—strictures, benign or malignant of the esophagus or cardia of a high degree, spasmodic or paralytic conditions of the esophagus, pyloric or duodenal stenosis. 2. In ulcer of the stomach accompanied by considerable hemorrhage, or when the usual methods of treatment have failed. 3. Incessant vomiting, no matter to what cause it be due. 4. In all conditions in which absolute rest for the stomach seems imperative—intense pains soon after ingestion of food; persistent hyperchlorhydria of a high degree; intense chronic continuous gastro-succorrhea. Pronounced ischochymia. 5. In typhoid fever and other severe lesions of the small intestine necessitating a complete rest of this portion of the bowel. How long a period it should be administered depends on the condition requiring it. In ulcers, or irritating affections of the stomach it may be relied on alone for a period varying from one to two weeks, when natural methods may be cautiously resumed. Where there is an organic obstacle in the esophagus or pylorus, rectal feeding must be carried on as long as it exists, and in operating cases until a few days after the operation—in inoperable cases indefinitely. After operations on the esophagus, stomach and small intestine, rectal feeding must be continued for a period varying from four days to a week or ten days. It should be preceded by cleansing injections of salt and water to thoroughly evacuate the bowel and the food enema given one hour afterward through a fountain or Davidson syringe, slowly, without much force. The amount may be from five to ten ounces and three to five such may be given daily. The substances which Einhorn gives are: 1. The different kinds of peptones and propeptones, the different beef juices dissolved in water. 2. Milk and eggs, six to seven ounces of milk, with one to two raw eggs well beaten up in it, with perhaps the addition of pancreatin. 3. Meat pancreatin consisting of five ounces of well chopped meat with two ounces of fresh pancreatin, one ounce of butter or fat with about six ounces of water. These may be altered for variety and in conjunction, injections of water are made to increase the amount of fluid absorbed. Usually saline solutions in quantities varying from a pint to a quart may be given twice daily.

47.—This article has appeared elsewhere. See The Journal of August 4, title 131, 319.

55. **Progress in Obstetric Practice.**—The special points mentioned are instruction of patients as to the best methods of getting through the process of parturition, and preparation beforehand; the hygiene of pregnancy; the question of diet as affecting the development of the fetus, in which matter Hoag thinks that Eichholz' diet method is worthy of further investigation as affecting the size of the child's head and facilitating labor, and the advantages of posture.

56. **Internal Antisepsis.**—Burr reports the results of experiments upon himself as to the effect of aminoform on the blood and urine which seem to show that, under normal conditions, free formalin is not found in the blood two hours after ingestion of an ordinary dose of aminoform. Aminoform is capable of preventing decomposition in both normal and acidulated blood and in both normal and alkaline urine. It must, therefore, be antiseptic and theoretically a valuable drug in infected conditions. He asks whether it may be possible to exhibit formalin or its salts under conditions in which free formalin may be found in the blood in bactericidal strength with immunity, just as it is found in the renal secretions. If this question can be settled affirmatively, its value in infectious disease will be greatly enhanced.

64. **Immunity.**—The ordinary theories of immunity are rejected by Reid, who thinks that the natural processes of immunization are as follows: The individual is infected by the micro-organisms and is poisoned by their toxins. If death does not ensue, these cells produce enzymes which digest the toxins and injure the micro-organisms. As digestion proceeds, a gradual scale of toxins is produced, and up that graduated scale the cells of the individual react until they become indifferent to the strongest toxins and are able to destroy the micro-organisms. Pasteur, he says, imitated this process in his rabies treatment, and Jenner did it unconsciously in vaccination. Immunization by snake venom is produced by attenuating the poison in the stomach, and it may be possible on the same lines to cure a disease by swallowing and digesting its toxins. All toxins, however, are not digested in the stomach, or at least are not rendered innocuous—morphin is an example. If it were possible to attenuate morphin in some way by altering it, this product might prove of curative value in acute morphin poisoning.

65. **Hysteria.**—Punton believes hysteria to be the result of a defect in the anatomical conformation or the physiologic functional activity and power of the higher cerebral inhibitory centers, leading to disorder in the mechanism in one or more organs dependent upon their specific influence, that is, it is due to disorders of the higher inhibitory centers which are the last to develop. He dwells also on the importance of avoiding the evil influence of suggestion and the necessity of control and removal from home influences as treatment for such patients.

66. **Transmission of Sounds.**—Outten has experimented with various animal membranes superimposed one upon another, and finds that sound can be transmitted in a much more perfect state than by simple, more rigid membranes such as are used by the graphophone. He says that in this way the human voice can be reproduced in all its qualities. In the transmission of sound moisture seems to be necessary to produce the best qualities. He suggests further investigation with the superimposed layers of various membranes to augment sound and interpret its quality.

71. **Bubonic Plague.**—Novy's article is a complete history of the bubonic plague from the earliest times until now. He traces the present pandemic by various routes back to Yunnan in China, but there are undoubtedly other foci like those of Gurhwal and the recently discovered ones in Uganda and

Kisaba in Central Africa. It is quite likely another exists in Arabia. The present pandemic seems to have reached nearly all parts of the world, South America, North America, and Europe, as well as Asia and Africa.

72. **Epilepsy.**—The principle point in Inglis' paper is the use of coal-tar derivatives in epilepsy. He has tried the different ones, but has come down practically to the exclusive use of acetanilid. He employs it in cases where the bromids have been thoroughly tested and failed. It is not necessary, he says, to use large doses, 5 gr. or even 3 gr. three times a day will often prove sufficient. He gradually decreases the dose if the fits do not appear while keeping up its regular administration. He says that its use is justified on purely empirical grounds, and it seems that we are more certain of the positive action with these than with any other drugs. The surgical treatment of epilepsy is not hopeful, and he does not speak highly of it.

73. **Administration of Drugs.**—The phase of the question considered is that of the relation of the administration of drugs to the meals, and this is sometimes difficult to decide. The drug may unite with some of the food or digestive fluids, or both, and produce an entirely new compound which may have effects absolutely different from those that have been expected. Certain drugs may need to be given at a fixed time before or after meals in order to have the expected effect. When, on the other hand, they are given on an empty stomach, absorption may be too rapid and irritation may be produced. As an instance of this he mentions quinin, which may cause gastritis if given in large doses on an empty stomach. The administration of iodin in the form of compound solution or tincture, if given during digestion, may unite with the starch and produce a substance as valuable for medicinal purposes as a glass bead or copper cent. The effects of lack of precision in the administration of drugs in reference to meals are not as bad as they formerly were. The first reason was the substitution of the simple prescription for the old polypharmacy. The second change was the adoption of other methods of administration than by the stomach.

77. **Pathology of Human Milk.**—One of the most common variations from the normal is that the proteids are very high in percentage and have little tendency to decrease. While, from experience with cow's milk, this should not make so much difference, we have learned that the high proteids of mothers' milk are almost invariably associated with marked dyspeptic symptoms in the infant, commonly called colic. Zahorsky thinks the explanation of this fact is that the high percentage of proteids favors the growth of gas-producing bacteria, such as the bacillus lactis aerogenes, or, more probably, the gas is produced from proteids, and the treatment must be to secure proper metabolism in the mother by restriction of animal food, water drinking, exercise, sleep, etc. The relief of the infant also must be attended to. He uses dextrinized gruel as a diluent, giving half an ounce to two ounces of the mixture immediately before nursing. This combination of feeding is excellent in many conditions. The second clinical picture caused by faulty mothers' milk is anemia, which occurs usually after the eighth or tenth month, when the breast-milk has become very weak in proteids, but sometimes it occurs earlier. The cure of this disturbance is supplementary feeding, the administration of iron and phosphorus compounds and attention to the nutrition of the mother. In some cases milk contains pathologic bacteria from some disease or lesion of the nipple or breast and toxic symptoms and gastroenteric irritability are prominent. In another class, besides inanition disturbances, nervous symptoms are very prominent. The question of psychosis as regards the mother is mentioned in this connection, but the etiology in many cases is obscure. In any case, when we can, it is of importance to preserve mammary secretion even if it be only in small quantities, as the child must be taken from the breast only as a last resort.

83.—See abstract in The Journal, xxxiv, p. 1003.

84.—Ibid., p. 1418.

86.—Ibid.

88. **Medicinal Vibration.**—This article by Adam is theoretical and based on the assumption that all physiologic and pathologic phenomena are due to vibrations of matter in the intermolecular and interatomic ether, and this idea is applied to disease conditions and their treatment.

92-93. **Plague in San Francisco.**—Pillsbury's paper is in substance the same as that abstracted before in The Journal on p. 320. The article by Power is simply its supplement, and both cover the same ground and express similar views.

100. **Rhizomelic Spondylosis.**—This disorder, which has been given the above name by Marie, is described by Frazier, with two illustrated cases. The ankylosis of the spine which is its characteristic, and also of the large joints and extremities, was well marked. The etiology has troubled the observers. Curiously enough nearly all cases have been in males. In the two cases reported there was a history of traumatism; in neither was there any hereditary predisposition to this or any rheumatic disorder. The disease begins primarily in the ligaments and in the articular cartilages of the periphery. Any lesions of the nervous system are unquestionably not primary, but are due to pressure on the nervous roots or by exostosis. The prognosis is not serious as to life, but recovery is not to be looked for. Treatment can accomplish little, except possibly to relieve pain.

101. **Phenacetin.**—The conclusions in this paper are as follows: 1. The moderate dose of phenacetin is without any distinct action on any vital organ. 2. Large doses lessen reflexes by a direct action on the spinal cord. 3. Doses of .5 gm. per kilo of body-weight—equivalent to a little less than one ounce for a 150-pound man—kill by arrest of respiration. 4. Doses even up to .5 gm. per kilo had no distinct effect on the circulation.

111.—This address has appeared elsewhere. See The Journal, xxxiv, p. 1445.

113. **Bromids in the Alcohol Habit.**—Fletcher offers a treatment which he says is not original, but was suggested by Dr. G. M. Schweig, in New York, in 1876, in his article on the "Cure of the Morphin Habit." It consists in giving large quantities of bromid and a rather rapid tapering off of the narcotic habit. In cases where this habit is of long standing and large quantities are used, say from one to two quarts of whisky, or 10 to 20 grains of morphin, he gives about 1 ounce of bromid with a somewhat reduced dose of morphin or alcohol during the first twenty-four hours. The next day he gives one-half the amount of bromid and one-half the habit dose. It is rare, he says, that they do not get over the exhaustive stage in less than forty-eight hours, and he has never known a case to fail to rally. They require, however, several weeks' careful nursing before they are able to attend to business.

115. **Typhoid.**—Heg reports the general results of his experience with typhoid at Fort Meyer, Va., in the fall of 1898, when it was the base hospital of the Second Army Corps. He thinks that only about one-half of the cases received were correctly diagnosed in the early months of summer, but that the diagnosis of mild forms of typhoid is often exceedingly difficult. The Widal test, which was made in all cases coming to the hospital, was sometimes the only positive basis for the diagnosis. He is inclined to believe, however, that so many cases of mild typhoid are liable to be unrecognized that he agrees with Prof. Dock that all cases of persistent temperature especially in the summer or early fall should be considered as guilty of typhoid until proved innocent. On the other hand, there are many cases which seem almost certain to be typhoid, but which do not react to the Widal test, and which are due to autointoxication or ptomain poisoning. These patients are apt to recover rapidly and are the cases that make the reputation of the quack as cures or abortions of typhoid. The different methods of treatment were tested at Fort Myer, and Heg speaks very unfavorably of the Woodbridge method. He does not believe the Brand method to be of the value claimed for it, and thinks that it is of most use in full-blooded, plethoric individuals with excessive temperature, and then mainly in the early stages. Reduction of the temperature by drugs is in all cases harmful. Intestinal antisepsis is undoubtedly useful, and he found salol rather the best drug as being the best for the stomach and as satisfactory as any. Strychnin proved it-

self to be the most valuable of all drugs when the heart was weak and delirium marked. It was recognized by all that the best results followed the old expectant plan, viz., as full a liquid diet as could be digested, as little medicine as possible, watching and meeting all symptoms, carefully supporting the heart and nervous system and reducing the excessive temperature in the least disturbing way. He was impressed by the following facts: 1. That while all cases are serious, with rare exceptions, they tend to recover, and will recover, barring accidents, under any conservative treatment. 2. While it is advisable to place all cases on a varied liquid diet, semi-solid or solid food does not do the harm that it is supposed to, excepting by disturbing digestion. 3. Relapses may follow all possible care and are mostly due to a new crop of bacteria rather than to solid food. He has not seen harm follow laxatives unless pushed too far, and he does not believe that temperature, unless excessive, over 104 F., is liable to do much harm. Hemorrhage may occur in any case, and he knows of no medicine that specially helps it. A number of cases of perforation were noted, but in no case was it advisable to operate. He afterward saw two patients who recovered after showing all the symptoms of perforation. The total death-rate up to the time he left Fort Myer was about 7 per cent., which he does not think was bad, considering the surroundings of the disease before being brought there.

118. **Opium in Infantile Diarrhea.**—While many practitioners believe that opium should have no part in the treatment of diarrhea, Crandall recommends its use in certain conditions. Its contraindications are, first: 1, in the first stages of diarrhea, before the intestinal canal has been freed from decomposing matter; 2, when the passages are frequent or of bad color; 3, when there is high temperature or cerebral symptoms are present; 4, when its use is followed by elevation of temperature or the passages become more offensive. It is indicated: 1, when the passages are frequent, with pain: 2, when the passages are excessively frequent, large, and watery; 3, in dysenteric diarrhea preceded by castor-oil or a saline; 4, in late stages, with small, frequent, nagging passages; 5, when the passages consist largely of undigested food, and the bowels act as soon as food is taken into the stomach. The method of administration is of importance. It should not be added to the ordinary diarrhea mixture, but should be given alone, which makes it easier to regulate the dose, and safer. The preparations are preferably paregoric and the deodorized tincture, morphin is very rarely required. The dose varies greatly, but should be as small as possible. The dose of paregoric for an infant three months old should be 2 minims; 1 year old, 8 minims; 5 years old, 30 minims. These doses are only approximate and vary somewhat according to individual needs.

119. **Gastrointestinal Infection in Infants.**—Babcock concludes that bacteria are not essential to digestive processes in the human subject, basing his opinion on experiments and clinical observation. The digestive action of bacteria is slight, and injurious compounds are frequently produced. The source of bacteria which cause gastrointestinal infection is chiefly cow's milk. He emphasizes the importance of avoiding contamination in milk, etc. Fortunately the organism has a power of resistance in a large proportion of cases, but this can not be depended on and undoubtedly many troubles are due to this cause. The methods of examining milk for this contamination are described and the details of sterilization given. Pasteurization is of value, but care should be taken that the milk is rapidly raised to the proper temperature, kept at that temperature for twenty minutes and then rapidly cooled. Some methods of so-called pasteurization are simple incubation of milk, and do not destroy some toxins that have been produced, and hence the child may be poisoned after the bacteria have been killed. This but emphasizes the need of securing the milk in as nearly a perfect condition as possible, and preventing contamination.

British Medical Journal, July 21.

Our Numbers and Our Work at the Close of the Century. George Eastes.—The presidential address of Eastes before the Metropolitan Counties Branch of the British Medical Association gives some interesting figures as to the distribution of medical practitioners in Great Britain. It shows that they are steadily increasing in their ratio to the population, and that in London at the present time there is about one doctor to every 800 persons, while in 1881 there was one in every 1000, and that a like increase has taken place in the provinces. The number of female physicians is also increasing, but the numbers are not formidable at the present time, there being only about ninety-two practicing in London. The increase of dispensary practice is also another matter of importance to the profession, it being authoritatively given out that the out-patient visits in London alone last year numbered 1,335,000. The conclusion of the whole matter is that the medical profession is becoming more numerous, and its paying work less in Great Britain, as well as in this country. The remedies for this condition are, he thinks, already in effect. The fifth year added in 1892 in the student's curriculum has reduced the number of entries nearly three hundred a year since that date, and Eastes believes that the English colonies will afford a resource for many physicians who are crowded out from Great Britain.

The Lancet, July 21.

Malaria and Malarial Parasite. Patrick Manson.—The author describes the morbid anatomy of malaria, the disintegration of blood, anemia, etc. As regards the latter he remarks that the parasite is not present in the peripheral circulation in the same proportion as the central; hence the unduly small number of them described in the blood tested as compared with the mischief they are doing. The periodicity of malaria, he thinks, is due possibly to the life stages of the parasites and in part also to the diurnal rhythm of physiologic processes. So far as known, the lower animals are immune to malaria, and there is a great variation in individuals in this respect in the human species. The clinical forms are described, and he considers especially the pernicious types, the most common of which is the pernicious comatose. When the patient is suffering from an ordinary attack, he suddenly becomes comatose, and may die unless skillfully treated. Another type is the hyperpyretic, often confounded with sunstroke, and in tropical countries, convulsions may initiate the attack in children. All these different types are explained by the brain sections, which show the capillaries crowded with malarial parasites. The practitioner in tropical countries should always suspect any sudden unexplainable attack to be malaria. The diagnosis should not be positive, but there is cause for suspicion. Black-water fever is a disease not recognized until within the last thirty or forty years, and its symptoms are described. Its mortality sometimes amounts to as much as 50 per cent.; only occasionally is it as low as 10 or 15, and it is almost sure to recur if the patient remains in the endemic area. As in other malarial diseases, the symptoms may appear after the patient has left the infected region. Manson calls attention to the popular fallacy of thinking that every one must have been exposed to its infection, or that malaria is constantly present in all tropical countries. There are some regions in the tropics where the disease is absent. There are few diseases so easily diagnosed. There are three pathognomonic tests: 1. The periodicity, not the diurnal, but the tertian and quartan periodicity. Quotidian periodicity should be absolutely ignored in diagnosis. Then there is the therapeutic test by quinin, which is not sufficient, however, to be entirely relied on, as we have not time to wait for it, and third and last, is the microscopic test. The treatment resolves itself into one thing, the use of quinin, which is as nearly a specific as anything we have in medicine.

Modern Methods of Amputating at the Hip-Joint. Thomas F. Chavasse.—The different methods of amputation of the hip-joint, as described by Chavasse, are: The method with the anterior and posterior skin flaps, and the muscles and vessels divided as high up and as close as possible to the pelvic bone by circular incision. The second method [illegible] t he calls the external racket method, t[illegible] steps differ somewhat, according to the [illegible] ea[illegible] sist in a circular skin incision, with a vertical incision joining it on the outer aspect of the limb from above the trochanter, and all the muscles and soft parts are cut through by circular incision reaching the bone. The femoral vessels are at once seized and ligatured, and steps taken for the disarticulation of the head of the femur. There is still another method which he mentions, that has been described by Estes, and is a modification of the German operation suggested by Professor Rose. The first step is the ligation of the common femoral vessels at Poupart's ligament, and division of the same between double ligatures. Short anterior and posterior skin flaps are then formed from without inward and the soft parts divided by gradual dissection close up to the pelvis, all known vessels being secured before they are divided, and the smaller ones being clipped immediately afterward. This is slower, but it can be carried out with one assistant, and the surgical apparatus is simple and slight. For obviating hemorrhage he thinks the Wyeth pins are the best means known, though in some cases he has used the compression of the abdominal aorta and digital compression by a skilled assistant. The questions of shock, age, pregnancy, etc., are considered in relation to amputation of the thigh. Chavasse believes that improving the technique makes the operation a less and less formidable one. The remarkable showing of Wyeth of a mortality of 12.3 per cent., is the best yet recorded.

Rupture of the Apparently Healthy Esophagus. E. J. McWeeney.—The author reports a case and analyzes previous records of similar accidents. From a study of the data, he concludes that the two main factors are softening of the coats, and sudden increase of pressure from within. The softening is due partly to the intra-vital digestion, and partly—at least in the case which he observed—to inflammatory infiltration. The intra-vital digestion is to be accounted for by circulatory disturbance, which in his case took the form of venous thrombosis, and by prolonged sojourn of peptic matters in the gullet from prolonged retching. The increased pressure from within is doubtless ascribable to the violent propulsion of the gastric contents into the lower part of the gullet, whilst its upper outlet is obstructed by the contracted state of the muscle—in other words, to want of co-ordination of the muscular action of the tube, probably due to exhaustion from prolonged over-activity. Whether a localized phlegmonous esophagitis—for that is the condition in the case now recorded—is a constant factor in these cases, it is, of course, impossible to assert in the absence of microscopical details of other cases. He thinks he is the first to establish the existence of this condition as a possible cause of rupture of the apparently healthy gullet.

The Varieties of Acute Pneumonia. Henry Handford.—The author reports a case of pneumonia with low temperature, though with typical physical signs, and reviews the etiologic varieties of the disease. One of the first examples of pneumonia is the influenza type, which he thinks accounts for many of the infectious cases that have been reported. Under ordinary circumstances, in good surroundings, pneumonia does not spread from one individual to another, but in these influenza cases there seems to be a direct contagion or infection. Another type which he mentions is what he calls "food pneumonia," due to eating poisonous food. Plague pneumonia, or the pneumonic type of plague, is noticed, and lastly, typhoid pneumonia, which he believes is only a special form of typhoidal poisoning.

Australasian Medical Gazette, June 20.

The Epileptic; His Treatment and Care. F. Norton Manning.—Epileptics are of interest from a social, medical and medicolegal aspect, and in this paper the author discusses their general character, number and treatment. The average epileptic, when the disease has become confirmed, is not, in Manning's opinion, an amiable character. He credits him with an ostentatious religiosity, with a very defective morality, and with general moral decadence. He thinks their number is underestimated, and he gives the figures for the various countries, but assumes that in New South Wales their number is perhaps not less than one to every 1000 of the population. Epileptics are often classed as insane and sane. This is hardly a definite distinction, as there is no marked dividing line between them. Even where there is no actual insanity, there is generally a certain degree of mental impairment. He calls attention to the automatism accompanying their attacks, which has a very important medicolegal bearing; we should be always on the watch in regard to this condition and its manifestations—the unexpected is particularly liable to happen. These cases are best treated in hospitals or asylums, where they may be controlled, properly dieted, and medically treated. For the large number, however, who are not actually insane, no due provision is made in Australia, and he pleads for special sanatoria for their care, and notices those of other countries. The moral treatment is important, and can be better managed in an asylum than among the patient's friends. There should be absolute prohibition of alcohol, only moderate use of tobacco, removal of possible sources of irritation, simple and well-regulated diet, and attention to the elimination. The medical treatment is largely bromids, but variations may be made which he points out. The treatment is almost always long and troublesome, and generally necessary for years, if not for life.

Hereditary Optic Atrophy. C. S. Hawkes.—The writer reports two cases in which optic atrophy seemed to follow in the *female line*, but *affected only the males*. Both are followed for four generations; in the first, the female had five children, all males but one, of two of whom the history is not known; the other two males became blind at the age of 30. The female child was not affected, married, and has nine children, five of whom are females and unaffected; three are unmarried, and one is married and has three male children, the oldest 19, none as yet affected. The two males became blind at the ages of 15 and 48, respectively; one, at present 28 years of age, is not blind. One female married and has two male and three female children; both the males and one female have become blind. The second family history is even more striking in some respects. A married B, who is said to have become blind. They had three children, two males, both blind, and one girl, who married and had five children, four males, all blind, and one female, not affected, who, in turn, had two children, both males, and both blind. The heredity in these cases is rather striking as showing the transmission of the defect through the female line, but involving males almost exclusively.

Bulletin de l'Academie de Medecine (Paris), July 3.

Circular of the Malaria Committee.—The committee of five, including Laveran, appointed by the Académie, has drawn up a comprehensive circular of instructions for the use of physicians, naturalists and travelers in malarial countries. It contains a detailed description of the parasite of malaria in all its phases, and of the mosquito, its host, with directions and suggestions for future research. The circular reiterates that neither the water, the soil, nor the air is directly the source of malarial contagion, and that the mosquito does not transmit the malarial germ to its young. Among the questions still pressing for solution are the age at which the system becomes accustomed to the malarial infection, and what type of fever determines it most absolutely. What becomes of the malarial germs inoculated in an immunized or "accustomed" individual? Do they propagate in the blood in this case or not? Is the immunity due to the fabrication of an antitoxin that neutralizes the toxic substances elaborated by the germ and poured into the circulation as the merozoites are liberated, or is the immunity due to a poison produced by the organism which kills the parasite? The study of similar parasites in animals is also of great importance. Adult mosquitoes can easily be raised from the larvæ for study, and can be caught by placing a test-tube over one. It flies up to the top of the tube, which is then corked, and the particulars written on a label pasted on the tube. A little water must be placed in the tube, and the insects can be kept alive by feeding them with a slice of banana or honey, or, if they refuse this, by allowing them access to a young bird still in the down, or a shaved portion of the skin of a small animal. The insects can be preserved in alcohol or pure glycerin, or mounted on pins. The committee will gratefully receive any information or answer questions on the subject. Address rue de l'Ecole de Médecine, 15, Paris.

Bulletin de la Soc. Med. des Hop. de Paris, July 5 and 12.

Permeability of the Pleura. J. Castaigne.—Widal and Ravaut report tests of the permeability of the pleura by subcutaneous injection of .3 sodium salicylate, followed by injection of the same amount into the pleura. The salicylate is eliminated more rapidly, and can be measured more accurately than methylene blue or potassium iodid, which have been used in previous tests. In one case of tuberculous pleurisy the pleural permeability was diminished, in one of pneumonic pleurisy the permeability was altered in respect to the length of time required, but not in the amount eliminated. In three cases of mechanical pleurisy of cardiac origin, the permeability was normal, but in another it was diminished. Castaigne communicates the results of further research in this line, which authorize the conclusions that when the permeability of the pleura remains normal, or nearly so, during the entire course of a pleurisy, its non-tuberculous character is established. Also that the stage of the pleurisy can be diagnosed by comparison of the serum and pleural fluid in respect to the freezing-point, and by study of the permeability of the pleura "from without," i. e., testing the passage of salicylate into the pleural effusion one hour after ingestion of 1 gram. The "augmenting period" of the pleurisy is characterized by pleural permeability from without inward, and by a difference between the freezing-point of the serum and of the pleural fluid. The moment when the inflammatory phenomena subside is characterized by the cessation of this kind of permeability, and by the appearance of isotony between the fluid of the effusion and the serum. The practical conclusion of his research is that a puncture should never be made during the "augmenting period," except as a last resort. At this stage the fluid forms rapidly again. When the fluid is isotonic, and the permeability from without is suppressed, if the pleura is absorbing well—showing "permeability from within outward" —puncture is useless, as the fluid will be spontaneously absorbed. On the other hand, if at this stage the pleura is not absorbing well, puncture is the only means to relieve the pleura of the accumulated fluid.

Pathologic Displacement of Mediastinum in Breathing. A. BÉCLÈRE.—Holzknecht recently called attention to the displacement of the mediastinum during respiration, which he had occasion to observe in a patient free from pleuritic effusion, and which he attributed to stenosis of the right bronchus of unknown origin. Béclère has encountered two similar cases, and carefully studied the conditions with the fluoroscope. He rejects Holzknecht's explanation, and asserts that displacement of the mediastinum during inspiration is almost invariably a sign of unilateral sclerosis of the lung, the mediastinum moving toward the sclerosed organ. It is a positive sign of sclerosis of the lung if the mediastinal displacement persists without change as long as the patient immobilizes his thorax in forced inspiration, and the variations in the transverse diameter of the image of the lung on the affected side during the two phases of respiration are scarcely perceptible. The diagnosis of sclerosis of the lung is confirmed by the lesser clearness and lesser extent of the pulmonary shadow, by the drawing in of the ribs, and the less open angle formed by their insertion in the spine, by the elevation of the diaphragm, and the shortness of its excursions. The displacement of the mediastinum is total or partial, according as the sclerosis involves the entire lung, or only one of its segments, and also according as the inspiration brings more or fewer ribs into play. This displacement might be due to sclerosis of a bronchus, but in that case it would not persist during the entire period of immobilization of the thorax in forced inspiration, but would vanish before the advent of the following expiration, while the shadow of the lung would enlarge in every direction.

Echo Medical (Lille), July 15.

Gynecology and Advertised Specifics. H. FOLET.—Several instances are related of the most serious results in various gynecologic affections, and especially cancers, from the use of remedies advertised in the lay press, some ridiculously useless, others directly fatal, by stimulating a latent neoplasm to malignant activity, and all baleful by the loss of precious time and opportunity. A typical case is that of a patient who had been operated on twice for the removal of a cancerous nodule in the mamma. When it appeared again, the patient, still in blooming health, refused another operation, and purchased an electric machine advertised as a cancer cure. In four months the nodule had become transformed into a vast, inoperable growth, with rapid cachexia and death. The electric treatment had been directly fatal by its stimulation of the neoplastic elements. The only remedy for such occurrences is to have suits for damages instituted promptly and without exception against the proprietors of the remedies. This would enlighten the public, and the firms would soon find the business unprofitable if the suits were properly managed, and if the damages awarded were presented to some benevolent institution. But in none of the instances related in this communication was Folet able to prevail upon the families to incur the notoriety of such a suit.

To Render Raw Meat Appetizing. P. CARLES.—Scrape a piece of beef with a sharp knife until nothing is left but the fiber. Press the scrapings through a fine sieve, and add to bouillon with a few spoonfuls of a purée of peas or beans, also strained. It is impossible to detect the taste of the raw meat in this combination. It should be served warm, and to heat it without cooking it is necessary to warm the meat slightly in a double boiler, and have the peas, the bouillon and the dishes hot.

[A correspondent writes to the *Progrès Médical* that the use of raw meat is a return to nature, that cooking is an arbitrary attempt to improve on nature, which cannot be justified. Cooking transforms a living into a dead thing, and it is these dead things, deprived of every vital principle, which we utilize to build up our tissues, contrary to all the examples furnished by nature. Raw-meat therapy is therefore a rational kind of organ therapy.—ED.]

Journal de Medecine de Paris, July 15.

Pumice Stone in Surgical Asepsis. MERIEL.—Instead of a brush, Meriel recommends a piece of pumice stone, boiled and kept in an antiseptic, as the most effective instrument with which to render the surgeon's hands aseptic, and "give him a new skin." Tests on dogs and rabbits, whose intestines and peritoneum were handled after the hands had been rubbed with pumice stone in soapy water, demonstrated the absence of pathogenic germs.

Infanticide with Umbilical Cord. DUFOUR.—This method of infanticide must be extremely rare, as only two are on record in France. Dufour relates a third case in which the cord was tied in a single knot around the throat, cutting deeply into the flesh.

Revue de Chirurgie (Paris), July 10.

Pneumotomy for Bullet Wound. M. CHRISTOVITCH.—A young man shot in the lung was immobilized for six days, when the threatening symptoms demanded surgical intervention. In an operation lasting only twenty minutes the fifth and sixth ribs were resected under a V-shaped flap; the hard point of the lung containing the bullet was seized with forceps, and the pulmonary pleura and the parenchyma of the lung were incised. A large amount of blood and pus escaped, and the bullet was removed, with three gangrenous fragments. Hemorrhage was arrested with gauze tampons; two drains were left in the pleura; the flap was sutured, and an aseptic dressing applied nearly encircling the thorax. Ether and 500 grams of artificial serum were injected, the latter repeated two days later. The patient was dismissed completely cured in two months, with not even a fistula left.

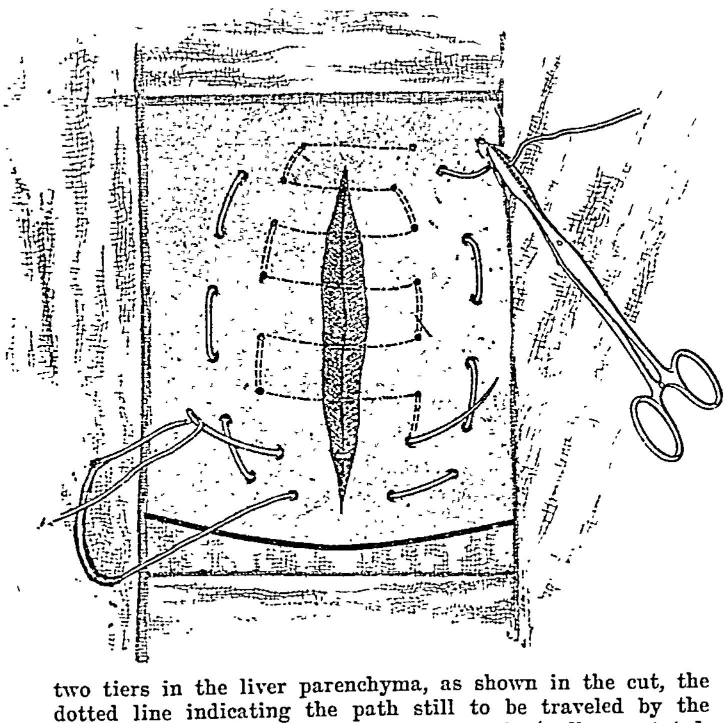
Interstitial Cells in Ectopic Testes. B. CUNEO.—Histologic study of two cases of ectopic testes, recently operated on, showed a remarkable development of interstitial cells in each organ, which seems to confirm the theory that these elements are of connective-tissue origin, and independent of spermatogenesis. From the pathologic point of view, it explains the frequency of malignant tumors in ectopic testes, and the predominance of sarcomata among these tumors. The practical conclusion is the necessity of abalation of every ectopic testis after puberty. The spermatogenic function is definitely abolished, and the testis in this case affords an excellent soil for the development of malignant tumors.

Revue Hebd. de Laryngologie (Bordeaux), June 30.

Best Anesthetic for Operations [illegible] Air-Passag MALHERBE.—The adv [illegible] position, [illegible] operations on the upper air-passages, are obvious, and it is possible and safe if ethyl bromid is used for the anesthetic. The bromid has no action on the heart, and no after-effects, while it is prompt and reliable, as Malherbe has demonstrated in 3024 operations. He urgently recommends it, and asserts that with a few simple precautions, there is not the slightest danger. It must be administered all at once, not fractioned, and with the least possible air. A very small amount, "the size of a five-franc piece," is first poured on a compress folded in four thicknesses and held over the patient's nose and mouth as he reclines on his back on the table. After twelve to fifteen seconds the left hand is slipped underneath, and 10 to 15 grams more of the bromid are poured on the compress, which is then held close over the mouth and nostrils with the right hand, the left sustaining the jaw. If the patient shows signs of suffocation, all that is necessary is to raise the compress, and allow a single deep inspiration of fresh air. Anesthesia is complete in forty to sixty seconds. It is indicated by a snoring respiration, a sensation of cold evaporation on the fingers holding the compress, as the expired air passes between them, and relaxation of the jaws and muscles. The patient can then be drawn to the edge of the table, and the head allowed to hang over, in the Rose position, supported by an assistant. If the operation is long, a small amount of bromid can be administered after five minutes, for a second and even a third time, thus obtaining as much as fifteen minutes for the intervention, and even ten minutes longer, as although the patient is waking, the analgesia persists for several minutes. It is not necessary to raise the patient's head for the secondary administration. There is no congestion after the anesthesia is complete.

Presse Medicale (Paris), July 11.

Method of Suturing Wounds in the Liver. F. P. Canac-Marquis.—The author of the method of suturing here described is a resident of St. Paul, Minn. It was first practiced on a young woodsman who had received an accidental wound in the side from a violent blow with an axe, cutting an incision in the liver 8 cm. long by 5 deep. With a long, round, curved needle, two double rows of U sutures were taken in two tiers in the liver parenchyma, as shown in the cut, the dotted line indicating the path still to be traveled by the needle. The lips of the wound were thus effectually coaptated, with no stitches near the edges. The wound was closed with drainage for twenty-four hours, and the patient made an uninterrupted recovery. The liver was sutured in the same way in another case, after ablation of a hydatid cyst on the upper surface, with equally favorable results. The catgut used was coarse, soft and flexible, and pulled through each time in the direction of the needle, with slow and gentle traction, never to right nor to left, for fear of injuring the parenchyma. The spaces left between the stitches were never less than 1½, nor more than 2 cm. long, and the lower tier was carefully taken below the deepest point of the wound, to avoid any dead space.



Constriction of Esophagus. J. Potarca.—Cicatricial constriction consecutive to ingestion of a caustic salt, in the observation reported from Bucharest, required catheterization. This caused perforation of the wall, purulent infiltration of the cellular tissues, ulceration of the bronchi, and rapidly fatal infectious pneumonia. The constriction was near the fourth dorsal vertebra, and the cadaver showed that the intramediastinal thoracotomy from the right side, advocated by the writer for such cases, would easily have reached and evacuated the pus, and afforded the only chance of safety. Quénu has advocated the left side for such operations, but the conditions showed that this route would have been far more indirect, tedious and dangerous. The operation in the observation related was postponed until the arrival of the surgeon-in-chief, when it was too late. This experience indicates that prompt, radical intervention is the only chance in such cases.

Semaine Medicale (Paris), July 11.

New Method of Treating Tubercular Osteoarthritis. C. Trunecek.—The aim of this treatment is to cure tubercular or other fistulæ by the application of a caustic that destroys the pyogenic membrane, induces an intense inflammatory reaction around the tubercular foci, and yet is not toxic for the tissues. The fluid used is a 20 to 25 per cent. solution of salts, with which the tissues are normally in contact in the serum, observing the following proportions: Sodium sulphate, 1.46 gram; sodium chlorid, 16.4; sodium phosphate, .5; sodium carbonate, .7; potassium phosphate, .94; water, 80. This fluid is injected into the fistula through a tube, at first gently, and then with great force, the opening plugged around the tube, and the sound skin protected with vaselin. The injection is continued until the fluid emerges clear and slightly tinged with blood. The cavities are then injected with 10 per cent. iodoformed ether; compresses are applied to reduce the inflammation, and the patient is kept in bed. There is smarting and pain on pressure, but these soon pass away, and this simple method of treatment cures without scars or hemorrhage. It is almost invariably effective, if the organism is capable of any inflammatory reaction at all. The serous discharge that follows usually brings out any sequestra. In one case of multiple tubercular caries in the humerus of an adult, a sequestrum .5 by 3 cm. in size was eliminated the third day after the caustic injection, and the cure was complete in three months.

Dermatologisches Centralblatt (Berlin), July.

Inunctions vs. Inhalation of Mercury. M. Saenger.—The idea has gained currency of late that the beneficial effects of mercurial inunctions are due to inhalation of particles. Saenger has been thoroughly testing his inhaler, invented for treatment of pulmonary affections with volatile substances, and finds that, with it, the mercury can be inhaled fully as effectively as when it is rubbed on the body. But he discovered that the therapeutic effects were not nearly so marked as with the same amount of mercury absorbed in inunctions, and consequently announces that the theory which assumes that inhalation is the essential factor in mercurial treatment is erroneous.

Muenchener Medicinische Wochenschrift, July 10.

"Milk Immune-Serum." V. Dungern.—In some recent experimental research at the new Frankfort Institute, guinea-pigs and rabbits were treated with cows' milk in the attempt to determine whether the products of epithelial secretion will produce a specific immune-serum, such as has been obtained for ciliated epithelium, spermatozoa, etc. The experiments were successful, resulting in the production of a hemolytic serum, which differs in its action from blood immune-serum, but so far no difference has yet been discovered between it and ciliated-epithelium serum. The milk serum is therefore an epithelium serum, characterized by its special hemolytic immune-body. This indicates that the same specific group is present in the milk as in the epithelium producing it, which coincides with the histologic observation that the protoplasm of the gland cells is directly applied to the production of milk. The specific epithelium serum thus obtained by preliminary treatment with milk suggests that human milk might be successfully utilized for purposes of immunization against carcinoma, especially of the mamma. All of the experiments with dogs and rabbits treated with human milk, however, have thus far failed to produce any hemolytic serum for human blood corresponding to that obtained with cows' milk.

Poisoning with Turpentin. H. SCHULZ.—Ten to twenty drops of pure oil of turpentin can be taken into the stomach in health without serious disturbances, but a small amount inhaled is liable to cause symptoms of poisoning. The minute particles which are inhaled are readily absorbed, and it is possible to induce poisoning with even a small amount taken into the stomach if finely emulsified, as was demonstrated by tests on a number of medical students. The central nervous system was always more or less affected, the spinal predominating over the cerebral symptoms, with muscular fatigue to exhaustion, cephalalgia, lowered pulse, digestive disturbances, constipation, and extensive acne in two cases, but no urinary nor respiratory symptoms.

Etiology of Fibrinous Bronchitis. OTT.—A simple catarrh in a man employed in grinding knives and scissors was aggravated by the metal dust, resulting in a fibrinous bronchitis, of an unusually protracted course. The association of staphylococci and pneumococci was probably responsible for the lingering course of the disease.

Tincture of Soap for Surgical Asepsis.—PAUL AND SARWEY.—Spiritus saponatus officinalis has been urgently recommended by Mikulicz and others as the simplest. least expensive, and most effective means of disinfecting hands and the field of operation. Their assertions are now authoritatively confirmed in respect to the effectiveness of the disinfection that can be obtained with it, by the tests instituted by the writers of this communication at Tübingen, scraping the hands afterward with a piece of hard wood, etc.

Passage of a Compress Into the Intestines. WUNDERLICH.—Another case is reported of a compress, 21 by 100 cm., evacuated by the anus three and one-half months after an ovariotomy. It had not caused any symptoms until a sudden diarrhea occurred, in the course of which it was discharged. In another case a compress was found in the peritoneal cavity, at the autopsy, thirty-six hours after a cholecystectomy, but it had probably nothing to do with the fatal termination. Wunderlich observes, "I always used to have my compresses and instruments counted, but since this occurred, I count them myself."

Wiener Klinische Rundschau, July 1, 8 and 15.

Latent Tubeculosis of Tonsils. L. RÉTHI.—In a hundred operations for ablation of hypertrophied tonsils on persons apparently entirely free from indications of tuberculosis, the writer discovered tubercle bacilli in the extirpated tonsils in six cases. The bacilli were found in the epithelium in one instance, and it was eroded, thickened, or knobby in most of the cases, affording favorable opportunities for bacillary invasion. He advocates removal of hypertrophied tonsils under all circumstances, without regard to clinical symptoms.

Splanchnoptosis. F. KRAUS.—Study of the pathogenesis of ptosis of the visceral organs shows that there are two varieties; one due to alterations in the general conditions of the intra-abdominal equilibrium, and the other to certain constitutional defects, of which the splanchnoptosis is merely the most prominent symptom.

July 8.

Pathogenetic Importance of Tonsils. E. ARON.—Two more cases are related which conclusively demonstrate the important part played by the tonsils as the primary lodging place of pathogenic germs. One was a streptococcus-pneumococcus infection, and the other abdominal typhoid, each following a typical follicular tonsillitis after the characteristic incubation period. The absence of glandular involvement in one instance suggests that the germs must have passed directly from the tonsils into the circulation. Aron is inclined to consider tonsillitis in its various forms, a disease *sui generis*, and in any event, the necessity of prophylactic measures is emphasized by his experience.

The Becquerel Rays. G. HOLZKNECHT.—The greater importance of the Roentgen rays has overshadowed the later discovery by Becquerel of the invisible rays emitted by uranium, and especially by pitchblende, a combination of the metal found in Bohemia. They differ from the Roentgen rays in being spontaneous and inherent, and by their far greater diffusibility, but most prominently by their property of rendering the air a good conductor for electricity. It is impossible to load a spectroscope or Leyden jar in the vicinity of the substance emitting the rays, and all attempts to break up the rays with prisms, to polarize them, to measure the light waves, have proved ineffectual. A bit of the black substance in the bottom of a test-tube will cause the fluorescent screen and other substances responsive to the Roentgen rays to shine faintly at a distance of 20 cm. A sensitized plate is blackened as by daylight, even in light-proof wrappings and when covered with other bodies—gold-leaf, aluminum, zinc, etc.—in certain thicknesses. According to its chemical reactions pitchblende is a combination of bismuth and barium, which are called "radioactive" in this combination, and certain scientists consider them two new elements, "polonium" and "radium." As days or even weeks are required to take a Becquerel radiograph, the process has as yet no practical interest.

July 15.

Serum Therapy in Septic Processes. HAEBERLIN.—Four cases of general pyemia, mostly puerperal, are described, all treated with antistreptococcus serum. There was slight transient improvement in one case, no effect in the second, but the morbid process in the third and fourth was arrested as if by magic. The difference in the streptococci evidently prevents any therapeutic action in certain cases, and a streptococcus serum, to be effective in all cases, must be derived from an animal immunized by means of all different varieties. The injections are harmless, and should always be tried as a last resort at least. Further tests of it as a prophylactic measure would be welcome.

Wiener Klinische Wochenschrift, July 5 and 12.

Colic Pains. R. LUCKE.—Colic is a pain from acute tension. This tension may be due to congestive processes, obstruction of the outlet, or other causes, and the effect is supplemented by the contraction of the circular muscles in the organs. The acute tension of a hollow organ in consequence of abnormally increased internal pressure does not cause colic pains if the tension has been gradually induced and the tissues yield. In case of organs with exceptionally developed circular muscles, remedies are indicated to relieve the cramp, but when the rapid increase of pressure is chiefly due to inflammatory processes, we endeavor to reduce the hyperemia. In this latter case we must not forget that we are neutralizing one of the internal processes for the expulsion of a foreign body. In cases in which the natural forces are manifestly inadequate to overcome the obstacles to its expulsion, our treatment of the colic is rational, but not in cases in which the natural processes have a prospect of success. Whether therapeutics should not have other aims than merely the relief of the pains in these cases, is a question for discussion.

Combination of Basedow's Disease and Myxedema. J. A. HIRSCHL.—A case was observed in Krafft-Ebing's clinic in which the patient, a woman of 33, previously healthy, had typhoid fever seven months before, and then immediately after a fright due to a severe fall, developed palpitations and the characteristic pulse. These symptoms subsided in two months, but the skin of the face and lower limbs became myxedematous, the uterus atrophied, and the memory became defective—the symptoms indicating a transition from Basedow's disease into myxedema. The struma was at first vascular, but later hard and fibrous. The skin was never moist with perspiration. This case suggests the possibility that the excessive and abnormal secretion of the thyroid gland may induce a series of symptoms caused by changes produced at certain points in the nervous system. These changes—and with them the corresponding Basedow symptoms—may persist even after the hypersecretion of the thyroid has ceased. The process may be cured, but the Basedow symptoms still persist. The changes in the nervous system might even continue past the period in which the hypertrophy of the thyroid is neutralized by atrophy. This conception would explain the occurrence of Basedow and myxedema symptoms in the same individual.

July 12.

Recurring Tetanus Gravidarum. C. Hödlmoser.—None of the stigmata of hysteria appeared in the case described, but the patient, a woman of 33, had experienced cramps and other symptoms of tetanus in each of her seven pregnancies about the time the first fetal movements were felt. They recurred about every two weeks from this until the end of the pregnancy. During the intervals she was completely free from any of these symptoms.

Zeitschrift f. Orthop. Chirurgie (Stuttgart), viii, 1.

Contraction and Ankylosis in the Knee-Joint. A. Blencke.—In all cases of ankylosis with tuberculosis, the writer's experience and study of the literature indicate that resection is the best method of treatment and also for ankylosis with considerable backward dislocation of the tibia, and genu valgum. Light cases of subluxation of the tibia can be treated by an arc-shaped resection. Helferich's method is preferable for angular ankylosis, as it does not shorten the limb nor interfere with its later growth, while it allows the gradual straightening of the member, and by the shape of the bony surfaces, guarantees their solidity. On the other hand, the best method of treating contractions in the knee-joint is by portable apparatus, severing the tense soft parts in certain cases. This does not require the patient to stay in bed, allows the contraction to be gradually and painlessly reduced, and avoids the dangers of *brisement forcé*. If the contraction is complicated with curvature of the femur or tiba, osteotomy is necessary for the latter.

Spondylitis Typhosa. M. Herz.—The wife of a physician in Dresden was recovering from an attack of typhoid fever, which had been complicated by suppurative choroiditis, when lightning pains and cramps appeared in the right limb with symptoms of paresis in the arm of the same side. By the fifth week the sacral region became the seat of intense pain, which radiated into the limbs, until the least movement of the spine and lower extremities was exquisitely painful. There was no fever, but the knee-jerk was excessive, and the dorsal muscles contracted. The patient was placed in a plaster bed with immediate relief of the pain and gradual recovery. Although no bacteriologic test of the spondylitis was possible, yet the typhoid origin was unmistakable. The case is the fourth on record.

Orthopedic Practice. A. Schanz.—In reviewing his experience, Schanz mentions that he has found a thick cotton bandage better than a plaster cast for the treatment of torticollis, care being taken to avoid too great pressure on the brachial plexus by compression of the clavicle. A correct attitude of the head is attained by having the child carry a light sand-bag on the head. In the treatment of coxa vara, he has always acted on the principle that the first and chief indication is the arrest of the deforming process. Anatomic correction is frequently found unnecessary when this has been accomplished. In one case diagnosed as congenital dislocation of the hip-joint, with Trendelenburg's sign, extreme painfulness and marked projection of the head of the femur on one side, the latter proved to be a myxoma on the neck of the femur, simulating the head in size and position, complicating double coxa vara. Another patient, a lad from a "bleeding family," and himself a "bleeder," in an advanced stage of coxitis, was completely cured in a year, which suggests that the lesion was hemorrhagic rather than tuberculous in origin. General treatment alone is considered sufficient for children under 6, with genu valgum or varum, and operative correction is attempted only in the severest cases. Supracondylar osteotomy is indicated for genu valgum, and below the epiphysis of the tibia and in the middle of the diaphysis of the femur in case of genu varum, always oblique and sometimes in as many as three places.

Gazzetta degli Ospedale (Milan), July 8.

Injections of Iodin in Surgical Tuberculosis. G. Mortari.—The unmistakable benefits derived from injections of iodin in fistulous affections are probably due to the neutralization of the toxins of the tubercle bacillus, rather than to any action on the bacillus itself, supplemented by the stimulation of the natural defensive processes. This communication describes a dozen typical cases of tuberculous fistulæ cured by injections of Durante's combination of iodin, .3 gm., and potassium iodid, 3 gm., in glycerin and water, āā 50 gm.

Hemorrhages in Influenza. V. Grossule.—The latest epidemic of influenza in Italy was marked in the writer's experience by a predominance of hemorrhages—epistaxis, bronchorrhagia, metrorrhagia and menorrhagia—in persons with no previous history of the kind, which frequently required extreme measures to arrest them. Another feature of the epidemic was the number of cases of malignant bronchopneumonia and the fact that none of the 400 children who had passed through an epidemic of measles the year before were attacked by the influenza.

Anaerobiosis. C. Fermi.—None of the culture-media hitherto used for anaerobic cultures have been absolutely free from oxygen, and Fermi has been testing some from which the last trace of oxygen was expelled by prolonged boiling under a layer of paraffin, or by other means. He announces that no cultures of the so-called anaerobes developed when the oxygen was rigorously expelled from the medium, and that consequently the complete absence of oxygen is probably incompatible with micro-organic life.

Queries and Minor Notes.

MEDICAL LAWS.

To the Editor.—Please inform me as to the law governing the practice of medicine in California, Oregon, Washington, Louisiana, and Iowa, and state the names and addresses of the respective State Board Secretaries.

Answer—California: A diploma, duly certified and sworn to from a recognized medical college. Secretary of the State Board of Examiners—regular—C. C. Wadsworth, M. D., 1104 Van Ness Ave., San Francisco.

Oregon: Examination by the State Board of Medical Examiners. Secretary, Byron E. Miller, M.D, Portland.

Washington: Same as Oregon. The secretary is either Dr. W. G. Tucker, Port Townsend, or J H. Hoxsey, Spangle.

Louisiana: Diploma from a medical college recognized by board, and examination. Secretary, Dr. F. A. Larue, 624 Gravier St., New Orleans.

Iowa: Diploma from recognized medical college and examination. Secretary of Board, Dr. J. F. Kennedy, Des Moines.

Lewiston, Ill., July 25, 1900.

To the Editor.—Will you kindly inform me through the columns of The Journal what is the law regulating the practice of medicine in the State of Arkansas? J. R. H.

Answer—In Arkansas there are county boards of medical examiners. Write to the county clerk of any county for details.

GOAT LYMPH AGAIN.

A few days ago one of the Chicago dailies printed a two-column article headed in big, bold, black letters: "Big Meet of Doctors, Great Conference of Physicians to be held in Chicago. Assemble in August. Three Days to be Given to the Study of Goat's Lymph Remedy. Doctors from All Parts of the Civilized World Will Make Reports on the Treatment." Then we are informed that one thousand physicians from the United States and Europe are to come to Chicago "on a peculiar mission," which is to exploit the goat-lymph business. We are told that the lymph "has been adopted by the medical director of the British Army," whoever he may be. "for use among the Queen's troops in India, and in this another great triumph has been scored by the Chicago scientists who have worked so hard to bring the lymph to public attention. When the British army medical authorities became satisfied that there was real merit in the lymph they expressed the fear that, being an animal derivative, it would not stand exporting to so hot a climate as that of India." Sic! "'You have undoubtedly got a wonderful remedial agent,' one eminent physician wrote, 'but I fear it will be useless to ship it to India. It will be better for you to come over here and show us how to prepare it.' But Dr. Hawley didn't go to India. He was too busy making lymph experiments for the benefit of American doctors. He just went to work and devised a means of preparing the lymph so it was climate proof and would retain its remedial qualities under all possible conditions of heat or cold, and it is now being used with miraculous effect in Hindostan."

The names of the "celebrated American physicians who will be in attendance" are also printed, and that our readers may not be kept in ignorance of those who are "celebrated" among American physicians, we print the names also:

Dr. Scott Stone, Cleveland, Ohio; Dr. H. W. Hartwell, St. Louis, Mo.; Dr. Ed. T. Smith, Buffalo, N. Y.; Dr. F. S. Holladay, Los Angeles, Cal.; Dr. C. S. Crandall, Utica, N. Y.; Dr. William E. Heisen, Denver, Col.; Dr. A. R. Rainear, Philadelphia, Pa.; Dr. O. K. Thompson, Detroit, Mich.; Dr. William W. Townsend, Rutland, Vt.; Dr. A. L. Flanders, Boston, Mass.; Dr. R. W. Steger, New York City; Dr. F. C. Holden, Brooklyn, N. Y.; Dr. A. W. Parsons, City of Mexico.

These are no doubt celebrated, for have they not paid $100 for the privilege of using the lymph and $25.50 for each ounce and a half of the stuff they use? Or if they are very celebrated, they have probably accepted this offer which we clip from one of the circular letters sent out by the exploiters: "We have a special lymph, the Roberts-Hawley lymph, which is very much stronger, that costs you $30.50 for each ounce and a half."

The Public Service.

Army Changes.

Movements of Army Medical Officers under orders from the Adjutant-General's Office, Washington, D. C., July 25 to 31, 1900, inclusive:

James A. Alexander, acting assistant-surgeon, from the Division of Cuba to San Francisco, Cal., for duty with troops going on foreign service.

David Baker, lieutenant and assistant-surgeon U. S. A., from the Department of Western Cuba, to San Francisco, Cal., to accompany troops on foreign service.

William H. Corbusier, major and surgeon, U. S. A., leave of absence granted, on the expiration of which to report for duty at Fort Columbus, N. Y.

Joseph J. Curry, acting assistant-surgeon, leave of absence granted.

Oscar F. Davis, acting assistant-surgeon, from Bloomington, Ind., to San Francisco, Cal., to accompany troops on foreign service.

Guy S. Dean, acting assistant-surgeon, from Kenton, Ohio, to San Francisco, Cal., for duty with troops en route to the Philippine Islands.

Albert W. Dumm, acting assistant-surgeon, from Columbus, Ohio, to the Department of California.

Julius A. Escobar, acting assistant-surgeon, from the Division of Cuba to San Francisco, Cal., for duty with troops going on foreign service.

John M. Feeney, acting assistant-surgeon, from Huntsville, Ala., to San Francisco, Cal., to accompany troops on foreign service.

Robert J. Gibson, major and surgeon, U. S. A., to report to the Surgeon-General for instructions.

Frank C. Griffis, acting assistant-surgeon, from Mt. Gilead, Ohio, to San Francisco, Cal., for duty with troops en route to the Philippine Islands.

Robert B. Grubbs, acting assistant-surgeon, from Washington, D. C., to the Department of California.

Philip F. Harvey, major and surgeon, U. S. A., leave of absence extended.

Edwin P. Hayward, acting assistant-surgeon, from the general hospital, Presidio of San Francisco, Cal., to duty with troops en route to China.

Joseph M. Heller, acting assistant-surgeon, from Washington, D. C., to duty at Fort Columbus, N. Y.

James W. Holland, acting assistant-surgeon, from Westfield, Mass., to the Department of California.

Thomas W. Jackson, acting assistant-surgeon, leave of absence granted.

Henry S. Kilbourne, major and surgeon, U. S. A., and medical superintendent, Army Transport Service, to proceed to Newport News, Va., to inspect the transport *Buford* and return to his proper station.

W. P. Lawrence, acting assistant-surgeon, leave of absence granted.

Wharton B. McLaughlin, acting assistant-surgeon, from the Division of Cuba to San Francisco, Cal., for duty with troops going on foreign service.

Lieven de Poorter, acting assistant-surgeon, leave of absence granted; relieved from duty in the Division of Cuba, to report at San Francisco, Cal., for duty with troops going on foreign service.

William M. Roberts, acting assistant-surgeon, from Baltimore, Md., to San Francisco, Cal., for duty with troops en route to the Philippine Islands.

W. D. Shelby, acting assistant-surgeon, leave of absence granted.

Thomas J. Strong, acting assistant-surgeon, from Burlington, Vt., to the Department of California.

William H. Tefft, acting assistant-surgeon, from Belmont, N. Y., to San Francisco, Cal., to duty with troops en route to the Philippine Islands.

Benjamin L. Ten Eyck, captain and assistant-surgeon, U. S. A., member of a board of medical officers at San Juan, P. R., to examine candidates for admission into the medical corps of the army.

Francis M. C. Usher, lieutenant and assistant-surgeon, U. S. A., from New York City, to San Francisco, Cal., for duty with troops en route to China.

Clement C. Whitcomb, acting assistant-surgeon, from Camden, Mo., to the Department of California.

Llewellyn P. Williamson, lieutenant and assistant-surgeon, U. S. A., from the Department of Western Cuba to San Francisco, Cal., for duty with troops en route to China.

William B. Winn, major and surgeon, Vols., from the Department of Western Cuba, to San Francisco, Cal., for duty with troops going on foreign service.

Alfred A. Woodhull, lieutenant-colonel, deputy surgeon-general, U. S. A., leave of absence granted.

Navy Changes.

Changes in the Medical Corps, U. S. Navy, for the week ended July 28, 1900.

Orders issued by Commander-in Chief of the Asiatic Station

Surgeon A. C. H. Russell, detached from the *Newark* and ordered to the Naval Hospital, Yokohama, Japan, for treatment.

P. A. Surgeon R. M. Kennedy, detached from the *Yorktown* and ordered to the *Newark*.

Asst.-Surgeon A. G. Grunwell, detached from the *Brooklyn* and ordered to the *Monocacy*.

Surgeons M. F. Gates and G. Rothganger, commissioned surgeons from July 7, 1900.

P. A. Surgeon R. Spear, commissioned passed assistant-surgeon from June 22, 1900.

Asst.-Surgeon M. K. Elmer, commissioned assistant-surgeon, from July 18, 1900

Marine-Hospital Changes.

Official list of the changes of station and duties of commissioned and non-commissioned officers of the U. S. Marine-Hospital Service for the seven days ending July 26, 1900.

Surgeon G. M. Magruder, granted leave of absence for fourteen days.

Surgeon C. P. Wertenbaker, to rejoin station at Wilmington, N. C., and upon being relieved by Surgeon T. P. Perry, proceed to New Orleans and assume command of the service, relieving Asst.-Surgeon J. W. Schereschewsky.

Asst.-Surgeon J. W. Schereschewsky, relieved from temporary charge of the service at New Orleans, La., and upon arrival of P. A. Surgeon C. P. Wertenbaker, directed to report to him for duty.

Acting Asst.-Surgeon Bailey, granted leave of absence for three days.

Acting Asst.-Surgeon A. W. Fisher, granted leave of absence for fifteen days during month of July.

Hospital Steward W. L. Stearns, granted leave of absence for twenty-three days from August 6.

Hospital Steward B. E. Holsendorf, granted leave of absence for thirty days.

PROMOTION

Junior Hospital Steward B. E. Holsendorf promoted and appointed Senior Hospital Steward.

Health Reports.

The following cases of smallpox, yellow fever, cholera, and plague have been reported to the Surgeon-General, U. S. Marine-Hospital Service, during the week ended July 26, 1900.

SMALLPOX—UNITED STATES.

Alaska: Cap Nome, June 20-July 10, 5 cases on vessels.

District of Columbia: Washington, July 14-21, 1 case.

Indiana: Michigan City, July 14-21, one case.

Kansas: Wichita, July 14-21, 1 death.

Kentucky: Covington, July 9-15, 3 cases.

Louisiana: New Orleans, July 14-21, 8 cases, 2 deaths.

Massachusetts: Fall River, July 14-21, 2 cases; Lowell, July 14-21, 2 cases.

Minnesota: Minneapolis, June 30-July 14, 23 cases.

New Hampshire: Manchester, July 14-21, 3 cases.

Ohio: Cincinnati, July 6-20, 7 cases; Cleveland, July 14-21, 20 cases.

Utah: Salt Lake City, July 14-21, 4 cases.

SMALLPOX—FOREIGN AND INSULAR.

Austria: Prague, June 23-30, 10 cases.

Brazil: Rio de Janeiro, May 19-June 22, 18 deaths.

China: Hongkong, June 8-23, 1 case.

Egypt: Cairo, June 3-10, 5 deaths.

England: Liverpool, June 30-July 7, 3 cases, 2 deaths; London, June 30-July 7, 17 cases.

France: Lyons, June 23-30, 1 death; Paris, June 30-July 7, 4 deaths.

Gibraltar: July 1-8, 1 death.

Greece: Athens, July 30-July 7, 2 cases, 2 deaths.

India: Bombay, June 12-26, 12 deaths; Karachi, June 10-24, 8 cases, 5 deaths.

Mexico: Vera Cruz, July 7-14, 4 deaths.

Russia: Odessa, June 23-30, 5 cases; Warsaw, June 23-30, 7 deaths; St. Petersburg, June 23-30, 3 cases, 3 deaths; Siberia: Vladivostock, May 1-31, 9 cases.

Scotland: Glasgow, July 6-13, 68 cases, 2 deaths.

Straits Settlements: Singapore, May 26-June 16, 1 death.

YELLOW FEVER.

Brazil: Rio de Janeiro, May 18-June 2, 34 deaths.

Colombia: Cartagena, June 30-July 7, 9 cases, 7 deaths; Panama, July 9-16, 3 cases, 1 death.

Costa Rica: Port Limon, July 17, 1 suspicious case.

Cuba: Cienfuegos, July 21, 1 case among soldiers; Havana, July 4-11, 21 cases, 5 deaths; Sagua, July 5, 2 cases.

Mexico: Vera Cruz, July 7-14, 4 deaths.

CHOLERA.

India: Bombay: June 12-26, 179 deaths; Madras, June 2-22, 2 deaths.

Japan: Osaka, June 23-30, 1 case.

PLAGUE—FOREIGN AND INSULAR.

Arabia: Aden, June 23-30, 1 case, 1 death.

China: Hongkong, June 2-25, 297 cases, 185 deaths.

India: Bombay, June 12-26, 185 deaths; Karachi, June 10-17, 17 cases, 16 deaths.

Japan: Osaka, June 19-30, 3 cases; Sakai, June 19-30, 1 case; Shidzuoka Ken, June 19-31, 1 case; Tamsui, June 1-14, 76 cases, 65 deaths.

Korea: Seoul, June 8-16, endemic.

Philippines: Manila, May 26-June 7, 4 cases.

Change of Address.

Dr. G. A. Bachman, from Burnips Corners, to Hopkins Station, Mich.

Dr. J. C. Blume, from Benton Harbor, Mich., to Mishawaka, Ind.

Dr. R. W. Bemis, from 2603 N. Fifth St., to 2512 N. Fifth St., Philadelphia, Pa.

Dr. C. W. Baker, from Trempealean, Wis., to Blanchester, Ohio.

Dr. S. B. Bennett, from Galesburg, to Canton, Ill.

Dr. J. R. Bradford, from Boulder, Colo., to Sanitarium St., *Battle Creek, Mich.*

Dr. J. M. Byne, from Waynesboro, to Augusta, Ga.

Dr. Alice Bennett, from Huntsville, Ala., to Wrentham, Mass.

Dr. B. L. Clary, from Sun Prairie, to Edgerton, Wis.

Dr. E. O. Church, from 591 W. Congress St., Chicago, to Watertown, S. D.

Dr. W. B. Coakley, from Virginia Hotel, to 297 N. State St., Chicago.

Dr. W. S. Carnes, from 22 Third St. N. E., Washington, D. C., to Box 47, Pierce P. O., Ohio.

Dr. J. A. Ascher, from Cherry Creek, to Lovelocks, Nev.

Dr. J. M. Asher, from 1527 Girard St., to University Hospital, Philadelphia, Pa.

Dr. W. A. Dickey, from 227 Twelfth St., to 1703 Jefferson St., Toledo, Ohio.

Dr. A. M. Earel, from Alma, to Lincoln, Neb.

Dr. W. W. Fox, from Atlantic City, N. J., to Orthopedic Hospital, Philadelphia, Pa.

Dr. E. S. Goodhue, from Kailua, Hawaii, to Honolulu, Oahu, H. I.

Dr. N. P. Grensel, from 42 Butternut St., to 440 Lincoln Ave., Detroit, Mich.

Dr. B. P. Goode, from 2012 Baymiller st., to 1812 Baymiller St., Cincinnati, Ohio.

Dr. F. E. Gibbons, from Mattoon to Eagle River, Wis.

Dr. I. B. Hayes, from Northampton to Florence, Mass.

Dr. C. P. Hayden, from Woburn, Mass., to St. Agnes Hospital, Raleigh, N. C.

Dr. W. A. Hickman, from 1409 Wood Ave., to 1319 N. Nevada Ave., Colorado, Colo.

Dr. C. C. Hummell, from Iowa Falls to Dike, Iowa.

Dr. J. A. Hart, from Colorado Springs, Colo., to Geneva, N. Y.

Dr. C. P. Judkins, from Seventeenth and Race Sts. to Rose Hill Park, Station I, Cincinnati, Ohio.

Dr. W. Johnson, from 1940 Fifteenth St. to 1414 U St. N. W., Washington, D. C.

Dr. A. C. Karsten, from Haricon to 584 Seventh St., Milwaukee, Wis.

Dr. A. E. Klein, from Washington, D. C., to Elmhurst, L. I.

Dr. I. P. Lyon, from Buffalo to Camp Wilmurt, Tarnesda, N. Y.

Dr. E. E. Levers, from Red Cannon to Almy, Wyo.

Dr. W. T. Liggett, from Colorado Springs to Cripple Creek, Colo.

Dr. C. W. Leonard, from Dotyville to St. Cloud, Wis.

Dr. H. F. Langhorst, from Aurora to 58 Evergreen Ave., Chicago.

Dr. J. A. Miller, from Beddow to Farmington, Mich.

Dr. H. G. Patillo, from Charlottesville, Va., to Milton, Ala.

Dr. L. E. Powell, from English American Building, Atlanta, to Lanier House, Macon, Ga.

Dr. W. M. Phelps, from Chicago, Ill., to Lincoln, Kan.

Dr. B. J. Read, from Charlottsville, Va. to Blackwell's Island, care M. T. S., New York.

Dr. H. Randles, from 648 Minnesota Ave. to White City, Kan.

Dr. J. L. Stewart, from Loomis, Neb., to San Pedro Mex.

Dr. H. T. Summersgill, from Wilmington, N. C., to University of Virginia Charlottsville, Va.

Dr. S. Smith, from New York to Skaneateles, N. Y.

Dr. S. M. B. Smith, from Fort Atkinson to 315 Third St., Wausau, Wis.

Dr. J. C. Steven, from Three Springs to Huntington, Pa.

Dr. A. J. Sibley, from Creedmore to S. E. Hudson, Austin, Tex.

Dr. L. Tibbitte, from Rockport to L. Tibbets, Rockport, Ill.

Dr. J. S. Troutman, from Fourth and Broad Sts. to 1711 Meyers St., Paducah, Ky.

Dr. L. C. Vincent, from 101 W. Fifty-second St. to 151 W. Eighty-fourth St., New York City.

Dr. R. T. Van Pelt, from Wabash and Twenty-second Sts. to 167 Dearborn St., Chicago.

Dr. H. W. Wellner, from 183 E. 117th St. to 10 E. 115th St., New York City.

Dr. H. Wilson, from Pittsburg to Somerset, Pa.

Dr. J. A. Williamson, from Mineral Wells to Dallas, Tex.

Dr. C. Vander Veen, from 331 Grandville St. to 77 Canal St., Grand Rapids, Mich.

THE JOURNAL OF THE
AMERICAN MEDICAL ASSOCIATION

61 Market Street : : Chicago, Ill.

Cable Address: "Medic, Chicago"

Subscription price: Five dollars per annum in advance

Postage in the United States and Canada, Mexico, Hawaii, Guam, Porto Rico, and the Philippines, free; foreign postage, $2.50. Subscriptions may commence at any time. Volumes begin with the first issue of January and of July.

MEMBERSHIP IN THE AMERICAN MEDICAL ASSOCIATION.

The qualifications for membership require that the applicant be a member, in good standing, of a state or local medical society entitled to send delegates to the annual meeting of the American Medical Association. A list of these societies will be sent on request. Applications must be accompanied with a certificate showing that the applicant is a member of a recognized society, and should be sent with the annual dues—five dollars—to the treasurer, Dr. Henry P. Newman, 100 Washington Street, Chicago. Members receive The Journal free. Subscribers to The Journal may become members of the Association without additional expense if they are members of medical societies recognized by the Association. Those desiring to have their names transferred from the subscription to the membership lists should send certificates as above, with a receipt for their subscription to The Journal, covering the current fiscal year.

FISCAL YEAR.

The fiscal year of the American Medical Association is from January 1 to December 31; and the annual dues paid by a new member cover only the fiscal year, no matter at what time of year the membership is obtained. Those who pay their dues and join the Association at the annual meeting in June, for instance, pay only for the fiscal year which ends with the December following, and the annual dues for the following fiscal year are payable the succeeding January, at which time the treasurer sends a statement to each member. Such members, however, are entitled to The Journal for the full year, even though the membership be not continued.

PAPERS READ AT THE ANNUAL MEETING.

"Every paper received by this Association and ordered to be published, and all plates or other means of illustration, shall be considered the exclusive property of the Association. . . The Board of Trustees shall have full discretionary power to omit from the published transactions, in part or in whole, any paper that may be referred to it by the Association or either of the Sections, unless specially instructed to the contrary by vote of the Association." (From Article V of the By-laws.)

NEWS.

Our readers are requested to send us items of news of a medical nature, also marked copies of local newspapers containing matters of interest to members of the medical profession. We shall be glad to know the name of the sender in every instance.

ORIGINAL PAPERS.

Articles are accepted for publication with the understanding that they are contributed solely to this journal.

COPYRIGHT.

Matter appearing in The Journal of the American Medical Association is covered by copyright, but as a general thing, no objection will be made to the reproduction of anything appearing in its columns if proper credit be given.

CONTRIBUTIONS TYPEWRITTEN.

It will be satisfactory to all concerned if authors will have their contributions typewritten before submitting them for publication. The expense is small to the author—the satisfaction is great to the editor and printer. We can not promise to return unused manuscript.

Half-tones, zinc etchings and other illustrations will be furnished by The Journal when photographs or drawings are supplied by the author.

ADVERTISEMENTS.

Advertising forms go to press eight days in advance of the date of issue. Therefore, in sending in copy, time should be allowed for setting up advertisements and for the sending and return of proofs. Advertising rates will be made known on request.

CHANGE OF ADDRESS.

In ordering a change of address it is important that both the old and new addresses be given.

REMITTANCES.

Remittances should be made by check, draft, registered letter, money or express order. Currency should not be sent, unless registered. Stamps in amounts under one dollar are acceptable. Make all checks, etc., payable to "Journal American Medical Association," except those for annual dues. These should be made payable and sent direct to the Treasurer, Dr. Henry P. Newman, 100 Washington Street, Chicago.

Original Articles.

THE SURGICAL TREATMENT OF CONICAL CORNEA.[*]

ROBERT SATTLER, M.D.
CINCINNATI, OHIO.

Surgery in the treatment of conical cornea has a limited application. The various surgical measures which have from time to time been advised and practiced are justifiable only in certain progressive or confirmed expressions of this congenital deformity of the eye.

In the main, the purpose of surgical intervention concerns itself with attempts: 1. To arrest an inexorable advance of a deformed central area of the cornea by converting this region—in part or altogether—into an opaque scar or a series of cicatricial lines, thereby affording a more or less effectual check to an otherwise hopeless progression. 2. To effect a betterment of vision in confirmed cases which have been rendered helpless in consequence of hopelessly reduced sight, after all other methods of treatment, including every kind and combination of lenses, stenopaic appliances, etc., have been discarded as useless.

ARREST OF ADVANCING DEFORMITY.

In taking up the first proposition, it must at once be stated that this tendency to progression again, declares itself only in a limited number of cases of this class. For the latter alone it is justifiable to attempt through the aid of surgery to bring about an arrest of this progressive advance of a conical deformity of the cornea, which, since birth, or for many years, has been known to be present, but which throughout a longer antecedent period has remained stationary. What starts it, or whether it is due to inherent local or general causes, remains a mystery. Furthermore, it must be added that the deformed region of the cornea is not in the exact center, but rather involves the paracentral regions, and of these again, that just below the mathematical center. It is also observed that this progressive advance commonly begins between the twelfth and twenty-fourth year. It is so slow in some cases, and the aid which corrective lenses afford is not infrequently so satisfactory—particularly if successive changes are made as the needs for failing vision demand—that, for a longer or shorter period, this progression is either not recognized at all or is assigned to a not unnatural increase of the complicated error of refraction which is present. The fact that the refraction in most cases is myopic makes this oversight during the earlier stages of advance not only a possible, but a common one.

It is also not infrequently observed that, whilst this increase of conicity affects both eyes, it is almost invariably more rapid and destructive in one eye, and leads in this eye to complete suspension of function, whereas, in the fellow eye, progress is retarded, or may even be entirely arrested.

It is, indeed, then, an important, as well as a difficult, question to decide whether in cases in which the progression has unmistakably begun, but is not rapidly destructive to vision and the comfortable use of the eyes is not too seriously interfered with—whether in such cases it is at all justifiable to interfere during the early stages of advance, or whether surgical interference should be deferred until vision falls below a standard of less than 0, and a person so affected is rendered helpless in consequence of his reduced sight.

The indications which may suggest whatever surgery is considered justifiable or necessary are not clearly defined. This congenital lesion is a rare one, and for this reason both common and individual experience are necessarily limited. Among the accepted disclosures recognized as clinical facts, it is not infrequently observed that in certain cases which have remained stationary for years, and in which suddenly and mysteriously a marked and progressive advance of this congenital deformity shows itself, this is again, after a variable period of time, lasting in most cases, months, and often even years—spontaneously arrested, leaving the patient a fraction of available vision for the most necessary practical needs. Another equally established clinical fact is that this progressive increase of the deformity is more rapid and more pronounced in one eye, and in this hopeless reduction of sight takes place, but in the fellow eye, the same process either does not advance so rapidly or terminates more fortunately in spontaneous arrest, leaving the patient a fraction of available sight. It is not easy to decide whether in such cases it is justifiable to practice interference, which, even in the most favorable instances, is beset with dangers and is extremely tedious, so long as a fraction of useful vision belongs to the fellow eye.

We must not lose sight of the fact that a spontaneous arrest may take place in any case at any stage of progression. By keeping this in mind, too great haste of surgical interference in cases belonging to this class is avoided. This is to be the more remembered in those cases in which the fellow eye is either defective or altogether blind from the same or some other cause.

For these and other reasons to be referred to, the indications for interference can only be settled along lines which apply to the cases in question, and which only the judgment and experience of the surgeon can determine.[1]

---

[*] Presented to the Section on Ophthalmology, at the Fifty-first Annual Meeting of the American Medical Association, held at Atlantic City, N. J., June 5-8, 1900.

[1] The first purpose of surgical intervention also bears directly upon that which was long a mooted question: whether the conical protrusion of the central region was solid and due to an actual increase or thickening, or, rather it was rarefied and due to an excessive or abnormal thinning of the layers of the cornea at this point. Clinical and anatomical studies of typical cases of conical cornea since then have established certain facts which were misinterpreted by the older German and English ophthalmologists. For instance, Himly—*Handbuch der Augenheilkunde*—regarded this excessive conicity as a solid growth or a morbid thickening, and selected for it the name of hyperkeratosis. Sir William Adams—*Journal of the Sciences and Arts*—shared this view and

This brings up questions of practical importance in every case in which operative treatment may be not only justifiable, but indicated. Foremost among these are: Can the surgical methods which have been practiced, singly or combined, in those cases which show an inexorable advance of an existing congenital deformity of the cornea, really affect an arrest of such progression? Are those methods successful which are directed to the cornea alone? Do they involve serious risks? Are they attended by a fair share of success? How explain the good they accomplish, granting that they really bring about a cicatricial flattening with increased resistance of the ectatic region?

The last is perhaps the most important question. It would indeed be an achievement worth striving for, if, in these cases we could verify, in part and in a certain proportion of cases only, the cherished theoretic conclusion that if we substitute opaque scar-tissue, the result of a carefully guarded traumatism, cauterization—galvanocaustic, especially—excision or abscission of the prominent cone for the relaxed and thinned tissues of the ectatic region—we would fulfill the most essential requisite toward bringing about a check to an otherwise hopeless and uninterrupted progression. If this could be brought about with reasonable safety, a supplementary iridectomy would add greatly to the betterment of sight and the purpose of surgical interferences be accomplished.

Unfortunately, however, this is not easy of attainment. It will not be denied that, in some instances, brilliant returns attend operative treatment on the cornea alone, undertaken with the specific purpose to reduce through cicatricial contraction the central deformity and its progressive activity so mysteriously and insidiously aroused. Experience with these cases will soon demonstrate conclusively that such attempts are fraught with exceptional risks. Either reaction out of proportion to the traumatism inflicted is excited, which may even terminate in loss of the eye, or, subsequently the scar-region undergoes repeated necrotic changes, and instead of offering greater resistance, the opposite takes place and the ectasia is more pronounced.

It can only be claimed for the surgical methods which are concerned with the cornea alone, that they are uncertain in their results in affecting an arrest of progression, and that they involve exceptional risks. This brings up another question: Is the central region of the normal cornea more vulnerable to traumatism, and, if so, is this tendency increased in a congenital deformity such as is present in these cases, with thinning, and doubtless also more precarious nutrition of the central lamellæ of the cornea? That this is the fact is the conclusion which has come to me from a limited experience with these cases.

They recall to mind other surgical experiences, such as the sudden starting up—after a long period of inactivity—of a violent and destructive endocapsulitis, in old and confirmed cases of partial or anterior phthisis of the globe with ectatic leucoma of the cornea. In such cases, a slight traumatism—a blow or abrasion of the central region of the cornea—sets up a lesion which in rapidity of progress and destructive tendency is exceptional, and can be averted only by prompt enucleation.

Occasionally also we see, especially in strumous children of African parentage, a fatal expression of pustular keratitis if it happens to localize itself in the very center of the cornea. In spite of every method of treatment, a hopeless infective lesion of the globe results, with loss of the eye.

So also in cases of common traumatism, such as the lodgment of a foreign body. If this is imbedded in or near the center of the cornea, it may, in exceptional cases, be followed—even if promptly removed, and with every caution—by violent and sometimes fatal reaction, taking on the expression of endocapsulitis. If meddlesome or careless interference is practiced, as is done by some mechanics, who, in certain shops, gain a reputation for dexterity in removing particles of emery or steel from the eyes of their fellow workmen—if the foreign body is imbedded in the center, the attempts at removal, which, in other parts, cause little or, at least, no serious reaction, sometimes result in a violent disturbance.

Several years ago a mechanic came to me with the history that on the preceding day a fellow workman had removed a piece of steel from the cornea with a penknife. I found a small infiltration in the very center of the cornea and a dusky, or rust-like, discoloration. It was assumed that an infection had occurred, and an unfavorable prognosis was given. The epithelial layer of the cornea was rough; chemosis of the ocular conjunctiva and proptosis were just beginning. In spite of heroic measures, in a few hours the cornea became hazy and an extraocular infection—endocapsulitis—developed amidst symptoms of intense severity. To anticipate prolonged suffering, as the eye was lost, on the third day it was enucleated. It may be said that the mechanic used a dirty knife, or that its point was rough and conveyed infectious material, or that infection was subsequently conducted along other channels. The most careful inquiry, however, failed to develop more than that the same service had been rendered to others on the same day. Since then I have had several opportunities to confirm this conclusion—that the central region of the cornea is more vulnerable to traumatism and is followed by reaction out of proportion to the injury inflicted Another and more common experience is that if a violent reaction follows in these cases, it

---

held "that the lesion was the effect of a morbid growth and that the short sight of the patient was to be attributed to the increased refractive power of the part which together with that of the crystalline lens brought the rays of light to a point far short of the retina, etc." For this reason he advised and practiced the removal of the lens, and in the case which he reports, and which Mackenzie—*Text-Book of the Diseases of the Eye, p. 659*—considered of sufficient importance to quote extensively, a brilliant success was achieved.

Wardrop—*Anatomy of the Human Eye, p. 819*—however, held to the opposite view, which since then has been generally accepted, that an abnormal thickening of the protruded region was not present, but that, on the contrary, the ectatic region was rarefied. In support of this view, he mentioned a case in which a slight blow upon the eye caused rupture of the cornea at this point.

takes on a fatal expression of endocapsulitis, or extraocular suppuration, conclusively showing that pyogenic infection traveled along the lymph-spaces—capsule of Tenon—and here has excited, first, an extraocular suppuration, to which is added later on an intraocular infection. Or, perhaps, it is only that the symptoms of the extraocular complication—capsule of Tenon—overshadow those of the intraocular for reasons which are well known. A recent experience again confirmed this statement. An eye with adherent leucoma and phthisis anterior had been blind for twelve years but absolutely free from all irritation or pain. As the result of a slight traumatism, the central ectatic region of the scar was abraded eighteen hours before I saw the patient. At the time of his visit the lids were edematous; the ocular conjunctiva chemotic; the globe dislocated forward and rigidly fixed; excessive pain; no discharge. The cicatricial area was abraded in the center but with no deep pitting; the remaining portion appeared dry and the entire region of the scar showed a peculiar leaden discoloration.

Vomiting had occurred several times and nausea was constant. The eye was at once removed. The capsule of Tenon and the tendons of the muscles showed advanced plastic inflammation, and when the globe was removed the internal surface of the entire capsule was covered with a distinct, pyogenic membrane. The globe was opened, and under the choroid, intraocular plastic inflammation was only in its inception.

To this may be added a case of conical cornea published in the Transactions of the Ophthalmological Society. In this case, for the relief of rapidly increasing keratoconus in a young woman apparently in the best of health, I proposed as a first surgical or exploratory interference, the excision of a narrow, wedge-shaped piece of tissue from a little below the center of the cornea. This simple excision of a narrow strip was followed by paracentesis, amidst the strictest aseptic precautions. Forty-eight hours subsequently endocapsulitis developed with such rapid and violent symptoms that enucleation was the only remedy.

Similar cases have been reported. One mentioned by Mackenzie as occurring in the practice of Adams, bears evidence that this complication was known even to the earlier English surgeons.

It must be admitted that disastrous complications may attend the most carefully planned and executed surgical measures, directed in the main with a specific purpose to the cornea. Experience also sufficiently upholds the fact that repeated paracentesis, cauterization, excision or abscission of the deformed region—in cases in which serious complications do not follow—effect in exceptional cases only an arrest and reduction of the central ectasia. It is a question even with these successful ones, whether the good which is accomplished is not brought about through the central opacity of the cornea, for it is this which aids the supplementary measures on the iris and lens, which almost without exception are necessary to improve or raise vision to a higher standard. For this reason those operative measures which involve a major amount of surgical traumatism to the deformed cornea should be avoided. Surgical treatment must be undertaken with no other prospect than to render opaque the central regions, but with no reliable hope that it will bring about greater resistance of the ectatic region. For this reason the simplest surgical measures should be chosen, and these, as is well known, consist of cautious cauterization and tatooage.

SECURING BETTER VISION.

The second proposition concerns itself with attempts to bring about a betterment of sight in confirmed cases of this ocular deformity, in which vision has been hopelessly reduced: either, as the result of extreme conicity of the central regions of the cornea following a mysteriously started progression, but which was spontaneously arrested or was favorably influenced by the treatment practiced—adjustment of lenses, etc.; or 2, because of an excessive congenital deformity; but in which there can be discovered no evidence that the progressive tendency referred to has ever taken place. In the largest number of cases of this class it will be found that an excessive congenital deformity is present without tendency to fatal progression.

The cases which belong to this class are often greatly and permanently benefited through the selection and faithful use of proper corrective lenses. Sometimes stenopaic appliances are of great aid, but as often not. Strong crossed cylinders, or any combination of lenses which after repeated empirical tests has been found to aid vision, may prove of great service, and such lenses decentered placed or held by the patient in certain positions in front of the eye may even afford an increase of vision over the same lens in exact position directly in front of the eye in the test-frames.

For this certainly smaller class of cases of an excessive deformity, but in which lenses afford a fair amount of vision, should surgery be advised? If vision falls below a standard which implies helplessness, this must be considered a measure of justifiable expediency. If progression has not taken place, such cases offer far better returns from surgical treatment than those already referred to. With these, however, the same statements hold good, though they apply with less force to these cases: to avoid all unnecessary surgery with the cornea, limiting it rather to cauterization, followed by tatooage of the ectatic regions, relying for the restoration of better vision mainly on the supplementary measures—iridectomy and removal of the lens, or both.

Surgical experience and clinical observations uphold two expressions of conical cornea.

The first is more frequent. It is more amenable to the measures ordinarily employed as well as to surgery. The second is less frequent and also less amenable to non-surgical treatment and fraught with more danger if surgery is resorted to.

In the first expression of conical cornea, the entire structure participates in the deformity, but the conicity of the central region is without exception more pronounced. If progression starts, it again finds its chief declaration in the central regions.

The apex of the central cone is generally sharp. Neither involuntary pressure of the lids nor that which is voluntarily exerted, affects, disturbs or alters the conical shape. The apex of the cone is not easily indented with the blunt end of a probe. Surgical experience, furthermore, discloses that the apex region of the central cone, in most instances, is abnormally thin. It may happen, however, that the affected region in this more common expression, may even be increased in thickness. Vision is generally correspondingly reduced, but can, in most cases, be benefited, even with advanced progress or excessive deformity.

The second expression of conical cornea is less frequently observed. The conicity of the central region comprises a larger area. Implication of the peripheric regions of the cornea, though pronounced, is not so marked as in the preceding form. In other words, the entire cornea is less conical, but a larger portion of the central area is more ectatic. In this form, abnormal thinning of this ectatic region, and, in particular, of the apex of the cone, is met with without exception. The normal pressure of the upper lid, in marked or advanced cases, is sufficient to distort the shape and outline of the conical protuberance. Forcible contraction of the palpebral fissure produces flattening of this region. Pressure against this ectatic central region with a blunt probe readily confirms that this region has a lesser resistance and is easily indented. Surgical experience also fully corroborates the rarefaction of texture at this point. Clinical experience also confirms other points, and that is that visible pulsation of the thinned area is noticed.

The surgical methods for the relief of conical cornea are many and have long been practiced.

The obliteration of the conical protuberance by repeated cauterization with nitrate of silver and other escharotics, led eventually to surgical measures which accomplished this same object of cicatricial contraction and opacity with a lesser amount of painful reaction and danger and in a shorter period of time. For this reason, the use of the thermocautery, and in particular, galvanocautery, has superseded the older methods, and this procedure is justly entitled to preference. More than this, cauterization carefully practiced in selected cases is at present considered one of the safest and most useful surgical methods. Even if undertaken for no other purpose than to transform the deformed but clear central region into an opaque one without any definite hope that a reduction of the conical deformity may be brought about, a very desirable aim is accomplished.

The observation that after an accidental rupture of the thinned central region, the scar which followed reduced the deformity, led, especially on the part of French surgeons, of which Desmarres was a prominent advocate, to repeated paracenteses, followed by compress bandage and rest.

Early in the history of the surgical treatment of conical cornea, supplementary interference on the part of the iris and lens was found necessary even in cases in which the primary object was realized. On account of the large opaque area which followed, and not infrequently anterior synechiæ, it was found almost without exception necessary to perform a small iridectomy.

The view current for a long time that the central ectasia was a thickening of this portion of the cornea, led to the suggestion, and also to the practical surgical experiment of abscission of the prominent cone, excision of wedge-shaped pieces of tissue from or near the apex region, splitting of the cone by crucial incision, with or without paracentesis, cauterization, tatooage, etc. All these methods, however, were found to have a limited application only. They were all fraught with great dangers, and the returns from such treatment, always tedious and painful, were so unsatisfactory that such surgical procedures were only practiced infrequently and with the greatest hesitation.

In the early history of the surgical treatment of conical cornea, the suggestion was made that removal of the lens was a practical venture and accomplished a most desirable benefit for the patient. This suggestion was made and acted upon by Sir William Adams[2] as early as 1817. He had, in a case of successful cataract extraction, in a woman with high myopia, observed that she could see better without any, or required much weaker convex lenses than are ordinarily worn by persons who had undergone an operation for cataract. He recognized the high myopia so uniformly present in conical cornea and suggested and successfully practiced the removal of the lens in a typical case. Useful vision was restored in this case.

During a long interval of time, little or no progress was made either in the perfection of old or the discovery of new methods. Some surgeons condemned operative interference entirely and others practiced it only in extreme cases. For iridectomy, iridotomy and iridenkleisis were substituted by some surgeons.

The knowledge gained from surgical experience and careful clinical studies of conical cornea enables us to summarize briefly: That the surgical treatment of this uncommon deformity of the cornea is attended by uncertainty and danger even in the most favorable cases. Also, that it is without exception tedious. If it is undertaken with the hope of improving vision by reducing the central ecstasia through cicatricial contraction alone, it will prove in most cases an unsatisfactory venture.

The simplest and least risky surgical method consists of the discriminate and cautious use of the galvanocautery, supplemented, if necessary by an iridectomy, iridotomy, or iridenkleisis.

Abscission or excision of the central ectatic region, repeated paracenteses, are one and all most uncertain in their final results. The most vicious resentment may follow the most cautious attempts of such surgical interferences and for this reason they should not be too hastily resorted to.

Experience with the more desperate cases suggests as the most rational plan of surgical interference: 1, the removal of the lens by discission or extraction; this is followed by superficial cauterization with the galvanocautery and tatooage—simply to render the ectatic region opaque, but not with the hope or object of bringing about greater resistance on the part of this locality, or, what is less likely to occur, a better restoration of shape and curvature of other parts of the cornea. This accomplished, it may be expedient to perform a small iridectomy, placed in the locality in which it may furnish the greatest possible good.

It must be remembered as an inviolable fact of surgical experience that the most carefully guarded traumatism to the deformed or central region of the cornea may be followed by fierce, and at times by fatal, reaction. In conclusion, it may be stated that surgical treatment is justifiable in a certain number of cases, and while not often one of imperative necessity, may be one of practical expediency, which, however, only the judgment and experience of a surgeon must determine in every case.

THE TREATMENT OF KERATOCONUS WITH GALVANOCAUTERY.*

HERMAN KNAPP, M.D.
NEW YORK CITY.

In 1892, I published five cases of keratoconus[1] which I had treated with galvanocautery.

Case 1.—Operation was performed on both eyes. On the left eye the apex was cauterized with a fine loop in an area of 2x3 mm. and then pierced, so that the aqueous spurted out. Healing was free from dangerous reaction, but slow. The chamber closed and opened seven times. Before the operation patient read J. 1 at 1″ and with —7D. 20/200: eighteen months after the operation he read J. 1 fluently at 10″, and with —4D.

---

[2] Adams, Sir Wm.: Journal of the Sciences and the Arts., vol. ii, p. 403, London, 1817.

*Presented to the Section on Ophthalmology, at the Fifty-first Annual Meeting of the American Medical Association, held at Atlantic City, N. J., June 5-8, 1900.

[1] Arch. of Ophthalmology, Vol. xxi, p. 540.

20/40. The right eye, on account of the slow healing of its fellow, was cauterized cautiously and repeatedly until I saw the aqueous just begin to ooze out. There was a good deal of reaction, and the lens having become cataractous—by overheating the aqueous—had to be needled. Recovery favorable. Vision with +12D. +4cyl. 20/70. The recovery has remained permanent. The young man went through Yale College, stood high in his class, and is now a lawyer.

Case 2.—One eye only was markedly affected. Sn. No. 6 at 1″. To avoid an irregular cauterization I had electrodes made with a convex, slightly oval end-plate, which I placed on the well-cocainized cornea, and withdrew it the moment it became red. After this I pierced the center of the eschar with a fine-pointed electrode. Undisturbed and rapid recovery. Read No. 2 at 3″; with —4D. 20/70.

Case 3.—One eye presented a very slight cone, but the other a marked one with a dense patch in the center, so that vision was particularly abolished. Operation, July 18, 1891, as in the preceding case, piercing eschar in center. No reaction for eleven days, when the anterior chamber was restored. Repeated attacks of glaucoma followed, which pilocarpin relieved. A telangiectatic adherent leucoma developed. August 30, a violent attack of glaucoma, partially relieved by eserin and morphin. September 1, downward iridectomy, immediate relief, permanent recovery in a week. A year later patient reads J. 1 at 4″ and with —9D. 20/70.

The severe reaction in this case, and in the second eye of the first, determined me to operate on the two other patients without piercing the cornea.

Case 4.—L. E., J. 1 barely at 1″. Operation Feb. 29, 1892. No reaction. Improvement of sight considerable; at the beginning of April, J. at 1¼″. Cauterization repeated in the same way in the same place. No reaction. Semitransparent scar in ophthalmoscopy. September 17, 1892, I was told that her eye had given her no more inconvenience. She read with the naked eye J. 1 at 10″. V. 20/50. Glasses no improvement.

Case 5.—The sixth eye is almost a repetition of the previous one—L. E., J. 1 at 1″—and with —15D. 20/200. Two cauterizations, one March 10, 1892, the second March 23, 1892. Permanent visual result, J. 1 at 10 to 12″; with —3D. —1cyl. ax. 25°, 20/30.

To study the effect of the galvanocautery on the eye I made experiments on eight rabbits (loc. cit.), which showed that the reaction and the subsequent scar are proportionate to the extent and intensity of the cauterization. Moderate burnings, with or without perforation, healed kindly and left circumscribed scars. Extensive and prolonged cauterizations were followed by intense iritis, suppuration, and even sloughing of the cornea. To the six eyes of keratoconus published before and here given in short abstracts I can add eight new ones.

Case 1.—Miss Edna D. had marked conus in one cornea. J. 1 at 1″, 2/200 for distance without glasses, i. e., about 15/200 with glasses. Galvanocautery with disc-like electrode, June 16, 1893. Some pain the first twenty-four hours; none later. November 1, second cauterization. November 11 upward iridectomy on account of central opacity. November 16, reads No. 2 at 6″. V. 20/200; with —3.5D. —2.5cyl. 20°, 20/70. No discomfort since.

Case 2.—Both eyes. Mrs. Mary F., Cohoes, N. Y., Keratoconus on both sides, with speck in right cornea. September 20, 1895, right J. 1 at 3″; left at 1½″; operated on both eyes. Undisturbed recovery. Small optical iridectomy on temporal side. October 8 and 31, 1895, R. Sn. 2 at 4″, 6/200; with 5 D. 17/200. L. Sn. 6 at 4″, 4/200; with —10D. 10/200.

Case 3.—Mrs. Robert B., Oceanic, N. J., aged 25. Keratoconus progressive in both, R. J. 1 at 3″, L. J. 1 at 1″; with her own glasses, R. —5 D. about 15/200; L. 4 cyl. 30° 20/50. Operated on R. E. November, 1897. No noteworthy reaction. Re-examined May 22, 1900. R. —8 D. —2 cyl. 30 ° 20/70.

Case 4.—Mrs. Bertha S., New York City. Keratoconus, R. more than L. Came May 16, 1898. Thinks that L. has been greatly worse after childbirth, three years ago. Now R. J. 1 at 1″, with —9 D. 20/200; L. 20/70, with —3 cyl. 45°, 20/50, J. 1 at 5″. Right cornea, two small maculæ at apex. Is positive that L. formerly was excellent. June 16, 1898, apex touched with galvanocautry, perforated with pointed electrode. Some secretion and pain. Slow healing. July 17, wound closed with anterior synechia. Soon afterward great pain occurred in eye, nausea, vomiting. Pilocarpin and morphia gave relief. July 19, iridectomy upward; no reaction, no pain, opacity smaller. Tn. and S. better, 20/70. Examined in May 1900. Eyes quiet. Right, adherent leucoma downward, large artificial coloboma upward.

The following four eyes have been operated on according to the method of Mr. Anderson Critchett, of London. He burns at low heat a large area superficially; then with a little more heat, a smaller area more deeply, and lastly with a smaller point at a dull maroon heat somewhat deeper still stopping short of perforation. He thus creates two zones and a small central spot, the whole bearing some resemblance to a concentric target. Over the area of the outer ring, where only the superficial layers are touched, the cornea in almost every instance regains its former transparency. In only two cases out of ten, on which Mr. Critchett has operated by this his latest plan, has he found it necessary to perform an optical iridectomy. The improvement in vision has, of course, varied in degree, but in every instance it has been very encouraging; in one case raised from 6/60 to 6/9, without any glass correction.[2]

Case 5.—Both eyes, Miss A. M. A., Watertown, N. Y. Eyes formerly very good. Now keratoconus, left more than right. R. 20/200, L. 10/200, with crossed cylinders. R. =J. 1 at 4″. L. at 2″. Point and opacity slightly below and down from center of cornea.

The left eye was operated on November, 1899, as follows: With a convex, disc-like burner at dull-red an area reaching from the center of the well-holocainized cornea down and outward about 4 mm. in diameter, is superficially singed. Holocain is dropped in again. After a few minutes a smaller zone within the former is treated the same way, and holocain dropped in again. Lastly the disc is placed cold on the cornea opposite the outer-lower quarter of a moderately dilated pupil, the current is closed, and the disc withdrawn the moment it is red. These three areas differ distinctly in color, according to the intensity of the effect. The center appears like a dirty brown depression, as if in it the whole corneal substance were destroyed, and the aqueous humor kept back by the eschar. I was careful not to let the upper limit of the cauterization go beyond the center of the pupil, in order to obviate the necessity of a subsequent optical iridectomy.

The young lady immediately after the cauterization saw 20/100 without glasses. This primary effect of the cauterization is known. It may be owing not only to the flattening of the cornea which we notice at once, but also to the diminution of the aqueous humor. The recovery was undisturbed. The sight was 20/100 (from 10/200).

The right eye was then operated on in the same way. It recovered without disturbance like the other. Its sight was raised from 20/20 to 20/70 with —2D.

Case 6.—Miss R. N., Bergen Point, N. J., keratoconus slight, non-progressive in R. eye, L. marked and progressive. R. =20/40; L. fingers at 6; reads J. 1 at 1″; with —20D. =10/200, cylinder gives no improvement. Galvanocautery February, 1900. Recovery smooth. Sight good, namely, June 2, 1900, with glasses =20/70. Reads J. 1 at 6″. Nevertheless, the cornea shows again a slight conical prominence, which may make another simple cauterization desirable.[3]

---

[2] From communication made at the Ninth International Congress at Utrecht, August, 1899.

[3] Done in June, 1900, without reaction, and good result.

Case 7.—Alcie A., New York, reads R. No. 1 at 1″, and has with —2D. S. =12/200. L. not impaired. January 17, 1900, galvanocautery. There was mild reaction from the cauterization, which soon subsided. Patient was discharged in eleven days; has not been seen again.

This makes a series of fifteen successive operations, all of which were more or less improved, as the subjoined table shows at a glance. I should not omit to mention that vision was noted as determined by glass-corrections before and after the operations.

FIRST SERIES—VISION.			SECOND SERIES—VISION.	
	Before.	After.	Before	After.
1.	20/200	20/40	15/200	20/70
2.	20/200	20/40	6/200	17/200
3.	7/200	20/70	4/200	10/200
4.	1/1000	20/70	15/200	20/70
5.	15/200	20/50	20/200	20/70
6.	20/200	20/30	10/200	20/100
7.			20/200	20/70
8.			10/200	20/70
9.			12/200.	Unknown. (Did well.)

The improvement of vision is not the only gain; the greater gain is the arrest of the progress of the deformity and degeneration. Though we know that keratoconus may become stationary at any stage of development, we commonly notice that, at least in one eye of the patient, the cone not only increases, but the cornea on and around the apex becomes patchy.

In my attempts at relieving keratoconus cases, I have not had to deplore the loss of a single eye, but in many cases the treatment by cauterization with silver nitrate has been inadequate.

The superficial galvanocautery is not much better. Seeing this, I, for a time, have thought that perforation was a necessary factor in securing the desired effect. The perforation in some cases was followed by bad consequences: slow healing, repeated openings and closures, anterior synechia, glaucoma. The cautious and progressively deeper cauterization with the galvanic current has obviated these prejudicial consequences and proved efficaceous. I am not unaware that my own cases, and I dare say those of other ophthalmic surgeons, are not numerous enough to warrant us against the occasional loss of an eye, but feeling our way cautiously and supplementing insufficiency of experience on man by experiments on animals will make our practice safer and more and more beneficial. In the manner of executing galvanocautery in keratoconus I shall endeavor to observe these two rules:

1. Never cauterize too deeply, and if the result of the first operation be imperfect, apply the convex disc electrode again to the place in which you want the subsequent cicatrical contraction to have the greatest effect.

2. Spare, if in any way possible, at least half of the pupilary area. If we operate early, even in restricting as we should our interference to the progressive cases, we have to deal with a clear cornea, the reaction will be least, and the visual result as well as the operative effect greatest.

I need not say that we should not operate when the least septic condition is present in the conjunctiva or in the lids and surroundings of the eye, in particular in the lacrimal sac.

DISCUSSION ON PAPERS OF DRS. SATTLER AND KNAPP.

Dr. S. D. Risley, Philadelphia—There is probably no topic in ophthalmology about which I feel like being less dogmatic than the subject of keratoconus. My own management of this affection has always been very conservative. Very early in my professional career I conceived the idea that it was one of those affections that belonged to diseases of the anterior segment of the ball and was primarily dependent upon a diseased condition of the uveal tract.

I think the treatment should depend on the stage of the disease in which we find the eye. If still progressive, which will be indicated by the fact that the eyes are painful and the patient is suffering with severe headaches, we shall find more benefit by insisting on a prolonged rest of the eye and enforcing this by the use of mydriatics, using them alternately with weak solutions of eserin or pilocarpin, and the use of a compress bandage in the earlier cases. With the idea of the disease that I had, that we were having a stretching of the anterior segment of the ball instead of the posterior segment, as occurs in the eyes of young myopes, due to a lack of nutrition, I have made much use of the bandage, filling up the spaces over the closed lids with cotton, closing them for twenty-four hours and when the bandage was removed using gentle massage through the closed lids. At night the bandage might be removed to put in a solution of eserin, as strong as will be borne without causing pain, and then renew the bandage after an interval of rest. This was my early management of cases of progressive conicity of the cornea, until such time as the headache and tenderness of the ball disappeared, and then while the pupil was still dilated I made careful measurements of the cornea by the Placedo disc and then through the stenopeic slit and otherwise gained the best visual results I could. I would then allow the pupil to contract and go over the optical study of the cornea again to pick out the best glass, often getting the best results with the crossed cylinders. It is usually a matter of pure empiricism as to what glass will give the most benefit.

I think conservatism in the treatment of these cases is in the majority of instances better than surgical measures, especially if we consider that it is a pathologic condition of the cornea which is apt to be progressive and due to an impaired nutrition of the eye itself. If time permitted I could present a considerable group of patients that had been thus managed, some of whom have been under my care now for a good many years, having been among my earliest patients.

I may say I have been greatly pleased with the visual results that Dr. Knapp has just rehearsed in our hearing, for they exceed the results that generally come from optical correction, but the cases I have referred to have been greatly improved by the conservative treatment, One young man has just concluded a college course and another is passing through his college course now. Another man I recall at this moment is the principal of a large educational establishment in the central part of Pennsylvania. He was absolutely unable to use his eyes at all when he first came to me he passed through the mydriatic and myotic treatment with compressed bandage, and when he at times found the bandage intolerable he would take it off for a while to reapply it when he felt better. His treatment ran over a period of four or six months, and he has had no trouble with his eyes, no asthenopia for years, but he drops in occasionally to let me see him. During the past year there occurred a slight change in the principal meridian of his left eye, and I had to change the axis of a cylinder he had been wearing for twelve years, a few degrees. He has gone back to work again with comfort.

Dr. Burnett—I would like to ask Dr. Knapp as to whether the visual acuteness he announced was taken without the use of glasses, or whether there was an optical correction.

Dr. Knapp—It was taken with glasses.

Dr. Sattler—I would like to emphasize the point Dr. Knapp made in reference to cauterization, that it be limited to bare perforation of the cornea. It may be repeated as often as necessary.

Gelatin in Hematuria.—Schwabe reports in the *Therap. Monatsh.* for June a case of hemorrhagic nephritis that was unmistakably benefited by subcutaneous injections of a solution of gelatin below the clavicle on each side, supplemented by a pint of a 10 per cent. solution of gelatin ingested during the day. No red corpuscles were to be found in the urine by the end of a week.

THERAPEUTICS OF TRAVEL AND CHANGE OF SCENE IN NERVOUS AND MENTAL DISEASES.*

RICHARD DEWEY, M.D.
WAUWATOSA, WIS.

This paper is suggested by the experience I have had in seeing a large number of cases in which travel or change of scene has been employed without resulting in benefit, or with apparent injury; also, to a less extent, in seeing patients improve or recover for whom travel had been recommended after they had received all the benefit they could be given by home, hospital or sanitarium treatment. Other patients have been observed who were incurable from the start, e. g., victims of paresis, who were sent traveling with the fallacious hope of benefit or palliation—in some cases the disease not being recognized—with useless trouble and sometimes disastrous results—explosion of maniacal excitement in public places, death in a foreign land or other distressing occurrences. Again, I have encountered cases of melancholia with suicidal impulses, or patients with delusions of persecution, who have made suicidal or homicidal attempts while traveling, to the great distress and confusion of all concerned. It is undeniable that great benefit may result from travel, when the conditions both of the patient and of the journey are favorable; and there are undoubtedly many cases where recovery results—of these latter we are less apt to hear, because they no longer seek medical aid. The relative proportion of benefit and injury is, therefore, difficult to estimate, but the inquiry seems worth while: In what cases is travel or change of scene likely to be beneficial, and in what cases, contraindicated?

Both nervous and mental diseases are included in this discussion, and properly so, for there are many patients with nervous disease pure and simple, or, at least, where no question of mental integrity arises, whose mental state is, nevertheless, a most important element, and may or may not be benefited by travel, while, on the other hand, there are many cases with pronounced insanity, for whom, however, travel can be made decidedly beneficial, if not curative.

I will here cite some cases illustrating the above remarks, confining myself for brevity's sake, to the bare outline of each case:

A woman, aged 60, of neurotic temperament, with some senile changes in the heart and blood-vessels, who had had a severe attack of neurasthenia some years before, suddenly developed insane jealousy regarding her husband, with whom she had lived happily for forty years. Her propensity to irritability and violent anger, with loss of self-control toward her husband and children, was so great that a change of surroundings was found necessary. She was sent to a Southern seaside resort, but grew constantly worse from day to day. She was then brought home, but could not be kept at home, as her conduct bordered on the maniacal, though she remained rational in everything except her jealousy. She was placed in a sanitarium, and after about three months' treatment regained her health. This same patient, in a previous attack of neurasthenia, was sent to California, and constantly grew worse there, being under the obsession of the idea that she would never reach home alive; that there was some incurable uterine disease, and no one but her home adviser could do anything for her. She was, accordingly, taken to her home again, and I was informed that on her arrival she was anesthetized and told that she had been operated on, though there was no condition requiring operation. She then went on to a fair recovery, being usually well for some years.

A patient suffering from neurasthenia was sent to Europe, with the expectation of cure from travel. While she was abroad a member of her family died; she hastened home; the obsession seized her that this relative was enduring endless punishment in the other world because not orthodox in his beliefs, and insomnia in aggravated form developed. Prolonged and rigorous rest-cure was tried, without avail; then a trip to a watering-place, but all her symptoms grew worse. Finally three or four months' systematic treatment in a private hospital for nervous and mental diseases resulted in such improvement that the patient was recommended hon where her convalescence was completed. In this case the trip abroad might possibly have been beneficial but for the death of the relative, but such events as this must be taken into account in sending a patient abroad. Another feature of the case deserving note is that the full completion of convalescence was best attained by a change to her home from the hospital at the right time.

Another patient, a woman of 50 who suffered from extreme insomnia and "phobias" of various incurable diseases, visited numerous European health resorts and traveled extensively at home without benefit, but improved very decidedly when treated for six months in a suitable hospital, and has been for a year at home in better health than at any other time since she broke down.

A patient with puerperal mania was sent into the country and temporarily improved, but grew worse at once on her return home. She was then again sent away on a trip, but became delirious. When she came under my care an acute delirious mania had developed, which proved obstinate and protracted, and for a time threatened death from exhaustion, but resulted in perfect recovery after five months' treatment.

A young man was twice under my care who on two occasions became insane while traveling, having been sent from home with the idea of benefit when in the prodromal, depressed and melancholy state of a psychosis, which would have been labeled "acute mania" under the usual classification.

I find on looking over the histories of a series of forty-six cases in which the patient was sent from home for recreation, that there were thirteen instances of unmanageable mental state, in which compulsory care or legal commitment became necessary. The remainder of the forty-six were cases of neurasthenia, hysteria or mild psychosis, in which, as no improvement was experienced from travel and change of scene, my advice was sought. Patients in numerous instances were taken to the *Mardi Gras*, to some large city for a round of amusement, to some fashionable watering-place with the same idea, and injury, rather than benefit, was the result. It was evident in some cases that the friend or nurse accompanying the patient was enjoying the diversions of travel and sightseeing more than the patient, and could not, or would not see that the ostensible object of the trip—the improvement of the patient's health—was not being furthered.

One patient who came under my care suffering from primary dementia had evidently broken down as a result of the strain of taking an epileptic brother for a European tour, during which constant difficulties and disagreements arose.

---

*Presented to the Section on Nervous and Mental Diseases, at the Fifty-first Annual Meeting of the American Medical Association, held at Atlantic City, N. J., June 5-8, 1900.

Five cases I have noted in which the effect of taking a patient suffering with neurasthenia or mild melancholia from the country to a general hospital in a large city was to precipitate a mental or physical crisis. The strange and unwonted sights and sounds of such an establishment and the contrast to a quiet country home were naturally unfavorable for a patient of this description.

Another patient, who was for many months under my care without benefit—a case of paranoia of long standing—illustrated in her earlier history the evil of sending patients who are undergoing rapid changes where they can not be under constant medical observation. This patient, a brilliant, accomplished young girl, by the direction of an eminent neurologist was kept under the care of a nurse and given frequent changes to the various health resorts and cities of the Atlantic seaboard. There had been no suspicion of mental disease entertained by the physician named, or, if there had been, it had not been communicated to her family, and their first knowledge that she was insane came from finding her at a hotel, where she had been for weeks, almost wholly refusing food under the influence of delusions, while the nurse allowed her to stay in bed with total disregard of all hygienic conditions. Her friends always believed her subsequent development of confirmed insanity was largely due to her neglectful management, though it is, of course, probable nothing could have prevented the ultimate appearance of mental disease.

Some experiences in sending "paretics" traveling which have come under my notice are here worthy of mention. Palliation is in such cases all we can expect from any treatment, but aggravation of the symptoms, exposure of the patient to unfortunate and serious annoyance, trouble and expense, have been the results in the large majority of such cases, judging from my own observation.

One patient was sent from Colorado to California last summer to visit friends. He attempted to engage in business there, became maniacal, wasted a large amount of money, and was finally brought across the continent in a violent and unmanageable state by two attendants, to be placed under my care.

Another, whose condition was not recognized by the medical man in attendance, was sent to Scotland, where he grew rapidly worse, and was brought back only to die in a few weeks. When the true condition became known to the family in this distressing manner there was sever censure of the ignorance, or lack of care, shown by the doctor in charge.

Another paretic, whom I saw at a hotel at the time of the World's Fair in Chicago, came from an Eastern city for recreation. He had been in a comfortable remission for about five years. After a few visits to the fair he developed a series of violent epileptiform convulsions, which lasted forty-eight hours, causing great alarm and distress to a large circle of friends. After being cared for for some time at the hotel he was removed home in a special train. His deterioration was somewhat more rapid after this seizure.

Another paretic, taken to a summer resort upon one of the great lakes, caused endless trouble before he could be brought home and committed to a private hospital, where he rapidly improved. He returned home in a few months, and remained quite comfortable for a year, when another threatened maniacal attack was cut short by his going to the same hospital for a few weeks only, and he has now been at home for some months.

Another case of this kind was recently sent from a Southern state to a large general sanitarium. The plain symptoms of paresis had not been recognized, or at least, no such diagnosis was communicated to the family, who had endured serious anxiety and expense they could ill afford in the hope of cure, when the patient was placed under my care. I could only advise the family that the condition was incurable and recommend a state hospital.

Similarly, I have been consulted in the cases of patients who had been sent to Colorado, to Japan and to the Pacific coast. Many other cases might be mentioned, but their main features would be the same.

What has been said above militates largely against travel as a method of treatment. Now, on the other hand, I would state from my own experience that I have seen much benefit from travel, especially in the convalescent stage. A recital of cases of this kind would be mostly the record of uneventful recovery, and yet I find that I have a comparatively small number of cases to report. Of seventy-six of my own cases in which travel and change of scene had been previously employed unsuccessfully, there were thirty-two cases of recovery while the patients remained under my care, and five for whom a further change of surroundings was later secured, and who subsequently recovered; four of these were cases of melancholia, and one a case of morphin habit, not of long standing.

One patient, a melancholiac with senile changes, who had been suicidal, and on a certain day expressed a wish to throw himself under a moving train, and attempted to do so, was taken on a long journey the next day by his daughter, much against my advice, but arrived at his journey's end alive.

Aside from cases in which cure has resulted, I have seen a large number of cases in which travel and change of scene were of great service, mostly in chronic conditions where nervous erethism was relieved by the diversion of thought to new and interesting objects. The old maxim, *cœlum non animam mutant qui trans mare currunt,* does not apply to cases of nervous and mental disease, for it is constantly evident in such cases that the suggestive influence of new objects does produce a change in thought and feeling. This change may be for the better or for the worse, according to the internal and external conditions in each case which I will briefly discuss at the close of this paper.

The essential elements of travel in general are quaintly described by Baedeker in a quotation from v. Sittewald, who wrote about two hundred and fifty years ago:

> Wer reisen will
> Der Schweig fein still
> Geh, stetem Schritt
> Nehm nicht veil mit
> Tritt an am frühen Morgen
> Und lasse Heim die Sorgen.

I venture to translate this freely as follows:

> When traveling your own counsel keep,
> Go onward with a steady step.
> Get every night a good night's sleep,
> Rise early on the morrow.
> Take little load
> Upon thy road:
> And pray, no trouble borrow!

The essentials of the above are: Suitable reserve in meeting crowds of fellow travelers, steady progress, a definite plan or itinerary steadily carried out, good sleep, small luggage and a care-free mind.

Certain of the above are, on their face, important for a nervous invalid. Such a one who can not secure for himself or have secured for him, freedom from outside impertinence or annoyance, a well-ordered plan of journeying, free from capricious change, a good sleep each night, and who can not travel without burdensome baggage and appliances, and enjoy a mind at ease and free from care, will hardly be able to benefit by mere divagation from place to place upon the earth's surface. The ordinary plan, the good sleep, the light luggage and the untroubled mind, are especially valuable for any invalid, and we see how difficult of attainment these are for neurotic individuals. A garrulous and capricious person, as so many of our invalids are, would become constantly involved and confused. A sufferer from insomnia would, as a rule, soon be worn out. A dyspeptic or over-particular person, or one ailing physically, as is the case with so many, would meet annoyances and trials which would nullify all good of the journey, and one given to worry and anxiety would grow worse instead of better. Of course, exceptions might occur to all these rules. A suitable companion, who had the confidence of the invalid, might overcome many of these difficulties, especially with a passive, easily-influenced patient.

There may be mentioned the bearing upon this question of certain mental states. Of course the acute stage of mania, melancholia or dementia would preclude travel. In chronic cases, suicidal tendencies and delusions of persecution and suspicion would contraindicate travel. All paranoiacs who are capable of becoming dangerous or homicidal under their delusions should be prohibited from travel. Paretics vary enormously in different stages of the disease and in their individuality. There are certain exceptional conditions under which such a patient may travel, but, as a rule, such patients, where the disease is active, are liable to fall into the hands of the police.

In considering travel for neurasthenics, hysterical patients and victims of hypochondria, it is especially important for the two classes first mentioned to determine whether rest is not more important than any other condition. Often the inclinations or wishes of the patient can not serve to guide us in the least; such patients crave change and novelty, and will evidently enjoy it, but may be all the while increasing nerve-exhaustion, while an unnatural excitement may impel them onward to the verge of collapse, or beyond it. Hypochondriacal patients, too, in some cases, have their morbid ideas confirmed, in others dissipated.

It may be broadly stated that the stage of convalescence from most nervous and mental maladies is the one in which benefit may be obtained from travel. Here a reservation should be made for those in whom profound prostration, both mental and physical, develops on the cessation of acute symptoms and the setting-in of convalescence.

I have spoken in my title of "travel and change of scene" considered as therapeutic measures and, in some cases it is necessary to discriminate between the two. There are many patients who could not travel from place to place with advantage, but who imperatively require a change of scene. A single change and remaining in new surroundings would often be beneficial, while repeated change would be injurious. Such single change, according to the state of the patient may be either a visit to congenial friends, a sojourn at some pleasure resort, a stay in the country, or the change may be combined with treatment by selecting a medical institution.

In studying this subject I have gone over the literature to some extent and made extracts. I quote here a few opposite sentences:

Esquirol says—quoting Seneca:—"Travel is of very little use in emotional disorders, hysteria, many cases of neurasthenia and affective insanity." He mentions Socrates' answer to a melancholiac who complained he had no benefit from travel—"I am not surprised. Do not travel with yourself." Esquirol proceeds: "Nevertheless the ancients prescribed journeys. They sent their patients to take hellebore at Anticyra and to make the leap at Leucate. The English send their melancholiacs to the southern parts of France and Italy, and even to the colonies. I have always observed that the insane are bettered after a long journey, especially if they have visited distant lands, the location and views of which have seized their fancy; if they have experienced the difficulties, the annoyances, the *contretemps* and the ordinary fatigue of travelers. Travel acts also by exciting the assimilative functions. It produces sleep, increases the appetite and the secretions. Convalescents who dread to reenter society, where they fear having to talk of their disease, are less discomposed after a journey, which is the subject of their conversation with their friends and relatives." Allowing for certain exceptions, the words of Esquirol are very wise.

Dagonet says: "Among the means that have been recommended we find walking and travel. But the value of this last agency has been strangely exaggerated. Hardly have the first signs of insanity declared themselves than the patient is advised to travel. Harmful at the beginning, this agent produces good results when employed at a later period, and especially during convalescence."

Marce, in his practical treatise, says: "Journeys are highly recommended in the treatment of insanity. They renew impressions, excite interest by the sight of new objects and may cause a healthful diversion from morbid preoccupations, but they are impracticable with disturbed (maniacal) cases, and full of danger with those who have ideas of suicide. They should be reserved for quiet cases, whose delusions tend to become fixed and to always revolve in the same circle."

Griesinger remarks: "Immer soll der Kranke den schädlichen Einflussen, die bisher auf ihn wirkten, entzogen, und es sollen ihm neue, wohlthätige zugeführt werden. In vielen Fällen debarf es hierzu einer durchgreifenden Umänderung aller Aussenverhältnisse; Ortsveränderung, kleine Reisen namentlich Fuss—und vorsichtig gewählte Badereisen, wenn die ausseren Vehältnisse solche gestatten (niemals aber Reisen in Grosse Städte, wo Hirn und Sinne des Kranken aufgeregt werden), sind hier oft vom besten Erfolge."

Says Regis: "Travel is an efficacious therapeutic agency in mental derangement, and at the same time is a salutary means of diversion. By removing the patient from his usual surroundings, it corresponds, indeed, to the very principle of treatment isolation, while at the same time it causes moral and physical distraction that reacts favorably on the mind of the patient. Specially recommended by Esquirol and some of his students, who had obtained good results with it, it is less utilized at the present on account of the inconveniences and the dangers to which it may give rise. We may employ it, also, in some chronic insanities with subjects more or less inoffensive, but in these cases it is only a means of diversion capable at the most of producing a relative sedation. Whatever the morbid form and the end proposed, the physician ought never to advise or permit an insane person to travel, except on condition that the patient should not be accompanied by any of his nearest friends; that the direction of the trip should be by an experienced person, in preference to a young physician; finally, that all precautionary measures should be taken to prevent, as far as possible, any disagreeable events or accidents."

Bucknill and Tuke say: "Should the threatened man travel? We think not often. Change of scene may do much good, but not constant change of scene with its labors, irritation and trials, especially if undertaken in foreign countries. This constant change of scene, which we call travel, easily suggests itself to friends and physicians. It is so obvious a method of getting a man away from places and people and circumstances which are irritating and obnoxious, and of removing him out of sight for a while that it is an expedient adopted with far more frequency than wisdom. We have known most disastrous results from it. Men threatened with lunacy who have been sent on their travels we have known to *commit suicide in foreign hotels and in mountain solitudes*, to have outbursts of raving mania in railway stations, and in city streets, and to get into the hands of the police for outrageous conduct. The friends of such a man who send him on his travels without sufficient watch and ward, commit a flagrant breach of private responsibility and of public decorum. As far as cure is concerned they might as well throw their friend from the house because a lunatic is said to have been cured by pitching accidentally on the right cranial spot. What they do, and know what they do, is to hide their friend for a while from the eyes of their own immediate public and to postpone the responsibility of taking proper steps for his care and treatment. . . . If he be attended by a medical man instructed in his case, by a trustworthy body servant and a good courier, and has 'put money in his purse,' there is no reason why the efficiency of foreign travel should not be tried under proper advice. . . .

"Travel within the four seas is quite a different measure, and with due provision for care and protection, for the right admixture of rest and fatigue, of change and repose, is a very fair and proper thing to try, not only in threatened yet undeveloped insanity, but also in many chronic conditions of mental disease, and especially also in the state of convalescence."

Clouston remarks: "A sea voyage, that favorite recommendation of despair, often does far more harm than good, and is attended with many risks. How many suicides I have known to result from this cause!"

Says Kellogg: "As a means of psychotherapy travel and change of scene in certain cases are unsurpassed. This form of treatment has been greatly abused by the sending of acute cases of insanity on a rampage from one country to another. The remedy is suitable in occasional cases in the initial stage of mental disease, but it is chiefly important when acute symptoms are at an end, and there is need of novelty and change to hasten and complete the mental restoration. In intelligent patients convalescence is often marked by mental depression, due to surging memories of the painful causes of the insanity, and to a certain conscious feeling of loss of social standing and of the confidence of friends. Instead of return to old surroundings and a host of disagreeable recollections, travel and change of scene are of the utmost benefit in confirming the cure in these cases. The rich insane, partially recovered with permanent defect, and without dangerous tendencies, should be allowed such pleasure in life as can be derived from travel. The view that all mentally unsound should be confined is grossly unjust, and hundreds of thousands of such persons are living in enjoyment of perfect freedom and comparative happiness. Such insane patients have a veritable mania errabunda, which should be checked rather than indulged."

I will now briefly present some results of the tabulation of cases encountered in my own experience when travel and change of scene were tried. The statistical method, so fallacious at all times, is perhaps of even less value here, but a few points may have some interest.

In five years' experience, out of more than 600 patients treated by me, 110 had been sent from home with the object of benefit or cure before coming under my care. Of these 51 had been sent with the double object of change and of medical treatment, nearly all to medical institutions, springs, etc.; 16 had gone for visits to friends; 23 to resorts of various kinds for recreation; 8 to the Pacific Coast; 12 to Europe, Japan and across the seas. None of these had recovered; most of them had grown worse; a few had improved, but still needed care and treatment.

Of the total of 110, 38 were practically incurable; 9 of paresis, 13 of paranoia, 11 were confirmed habit cases, 2 senile, 1 ataxic, and 2 epileptic. Of the 73 possibly curable cases, 36 recovered after an average of three or four months' treatment; 10 of these were depressed and exalted forms of psychosis; 7 neurasthenics; 5 had hysteria; two were habit cases. In the 73 cases there were 18 suffering from delusions of persecution, and of these 10 were cured, but I have not known a case of this kind to improve by travel.

In conclusion I may summarize my remarks as follows:

Travel and change of scene for mental and nervous maladies can not be judiciously prescribed except by careful consideration of the individual case. Travel may be good in one stage, and bad in another of the same disease. If the patient grows worse by travel, this does not prove the treatment bad, for some cases will grow worse whatever is done. It may even be necessary to make a careful experiment before the question can be settled. Another fact regarding travel is that a great deal depends upon the manner of its regulation. Patients who can command every facility for comfort and safety and an experienced medical escort, could travel where such a course would be injurious and dangerous for one of moderate means.

Again, we must discriminate between cases in which a curative result may be expected and others in which palliation is all that is attainable.

Certain symptoms may be said to raise a strong presumption against travel. In nervous diseases the real weakness of neurasthenia and hysteria—often masked by an excitable and irritable state—require rest rather than motion, though the patient outwardly appears strong, and is himself incapable of knowing or judging the limits of his strength.

Certain self-centered patients who are incapable of giving attention to any external object can gain no benefit from travel.

In mental diseases, delusions of persecution, the presence of elements of danger to self or others in the mental state, suicidal or homicidal tendencies, active and changing mental conditions, especially with visual and auditory hallucinations, will generally forbid travel.

In the convalescent stage of all these diseases, travel may be expected to prove most efficacious.

In sending a patient for travel or change of scene, some suggestions may be offered:

In most cases where a neurotic patient is sent from home, safety and welfare will be best consulted bv combining treatment with the change of surroundings. The patient should have access to a well-qualified practitioner, or, perhaps better, enter a medical institution capable of giving the recreation and supplying the diversion without the risks of travel, and with medical supervision otherwise not attainable unless a physician accompanies the patient.

Visits to friends by a nervous invalid except when convalescence is well established, are of little use, and may be very injurious.

Long journeys to Europe, to the Pacific Coast, etc., should be very carefully considered in all their bearings before undertaken.

DISCUSSION.

Dr. E. G. Carpenter, Columbus, Ohio—I wish to say a word with reference to one class, and that is in regard to the cases of melancholia, because there is a general vagary, even among the profession, that diversion and getting the patient away from home will tend to convalescence in melancholia. The reader has cited cases which show that it meets with failure. Those people that are interested in themselves and self-centered find it annoying to see things, be entertained, and be where many people are. It irritates them and does them absolute harm, and above all, they are cases which should be kept quiet until convalescence. When that is established it will be time for diversion and travel to be brought most effectively in play.

Dr. H. A. Tomlinson, St. Peter, Minn.—The chief essential to success in the care of cases of this kind that are traveling as a part of their treatment, is the caretaker, and I believe many of the failures resulting are due to the fact that the person taking care of the patient is not competent. The first element that enters into the failure of nervous health is loss of self-control, accompanied by morbid self-consciousness, and unless there is some one with the patient who has the character and strength of will necessary to control the patient, it does not make any difference what he attempts to do, his efforts will almost surely fail. Another point is the necessity to discriminate as to the attitude of the patient toward his surroundings; whether he wants to seclude or exploit himself. It is well to recognize that the patient will as a rule want to adopt a line of conduct which will feed his morbid self-consciousness in the direction of his mental perversion. Therefore he must be firmly and persistently antagonized and compelled into the proper attitude toward his environment. It is my experience that the importance of these tendencies is not sufficiently recognized; consequently the caretaker is inclined to follow the line of least resistance and accede to every whim of the patient that does not interfere with his own comfort or convenience.

Dr. J. H. McBride, Los Angeles, Cal.—Neither in cases of incipient insanity nor in those cases in which the disorder is fully developed is travel advisable. In certain exceptional cases in which there is danger of the development of insanity the diversion of travel may be beneficial with proper companionship. Travel is mentally and physically taxing for the well, and it is very liable to be harmful to those who are insane or as yet imperfectly recovered from an attack. A very important part of the management of the insane and of those who are convalescent is that they have a quiet, undisturbed, even monotonous, life, with, however, a certain amount of variety, but without excitement. The proper adjustment of interests to their needs demands the nicest discrimination and excludes novelty or anything that tires or excites. As the recently cured morphinist is weak in self-control and incapable of enduring stress, so the recently recovered insane person is weak and is mentally unstable, and to send such person home or traveling before the normal stability and resistive power of the brain is regained is as unwise as to dismiss a fever patient as cured when the temperature drops to normal. There may be occasions when travel is a choice between that and the patient going home too soon. When the insane person has given up his delusions and talks sanely he is liable to think he ought to go home, and it may not be easy to convince him and his family that he should remain away from home for a long period. In such cases one may find it advisable to have the patient travel. The redevelopment of the mental stability of the recent insane is a slow process, is in fact a re-education, a growth, and the friends should understand that months or a year may be occupied in getting back the normal mental vigor after the active symptoms of insanity are gone. When these cases travel they should go about it in the most quiet way and thus avoid hurry and tire. The cases, too, should be carefully selected, for intelligent and cultured people can travel under such circumstances with greater safety than those who lack the interests of such people and to whom travel is more of a dissipation, and therefore an excitement. It is difficult, however, to lay down rules. The question must be decided upon the conditions of each case. The question of travel is one about which the alienist can easily make mistakes, and when there is any doubt any proposition for travel had better be vetoed.

MORPHINISM FROM THE STANDPOINT OF THE GENERAL PRACTITIONER.*

T. J. HAPPEL, M.D.
TRENTON, TENN.

A practitioner of medicine in a large city, as a rule, has not as intimate a knowledge of his patients and patrons as his confrère in the small country town of two or three thousand inhabitants. In the cities, unless it be an exceptional case, the statement of the patient must be accepted as our basis upon which to draw conclusions; but in the smaller towns, nearly every one is personally known to the physician, who may have had, in a long life, a personal knowledge of three generations. It has been my own experience in several cases to have had a knowledge of as many as four generations of several of the families for whom I have practiced, and in cases referred to in the subsequent portions of this article, frequently three generations have been my intimate acquaintances. It is just such a condition as this that will make statistics honestly furnished by general practitioners in the country of fully as much value as hospital records; for it is a well-known fact that the morphin habitué will both lie and steal, if it become necessary, at any time to get a supply of the drug.

INCREASED CONSUMPTION OF OPIUM.

The alarming increase of the amount of opium imported into this country, far exceeding the legitimate demands brought about by an increase of population, gives one a slight idea of the rapidity with which we are becoming a nation of opium-eaters. In 1860, the United States imported 72,000 pounds of opium; in 1880, 372,000 pounds, and in 1893, nearly 1,000,000 pounds, an increase of sixteenfold in forty years, with an increase of about twofold in population.

If 72,000 pounds was sufficient for all medical uses in 1860, certainly it has been used largely in other ways since that time. A druggist in a town of 2500 inhabitants, laid in forty-eight ounces of morphin as a supply for his drug store for three weeks, and yet there were three other drug establishments in the same town. The vice grows rapidly, and the end of the course is not yet. We inveigh against the use of liquor. Prohibitionists grow eloquent in declaiming against the evils resulting from drink, and overlook an evil which is poisoning the very sources of all that ought to be good. Women, as a rule, do not indulge in the use of alcohol, especially those in the upper strata of society; would that I could say that they are equally free from a more blighting vice. High living, the demands of modern society, and efforts to keep pace with those more able physically and financially, soon produce such a state of the system as to demand a stimulant, and a dose of morphin is used for the relief of some real or imaginary trouble. The relief once obtained is again demanded, and in a short time the confirmed morphin habitué is the result. It is not my intention to attempt to trace the development or progress of morphinism, but to present some facts connected with morphinism with which I am conversant as a practitioner of medicine in a small city.

EFFECTS OF OPIUM ON FERTILITY AND ON CHILD IN UTERO.

In a article written some years ago, I detailed the histories of several patients, showing that the morphin user does not become sterile, or lose all sexual appetite. In that paper cases were cited where the users of the drug continued to bear children, in several cases three, in another four, and in yet another two—though in this last case the mother aborted—and in another one. These cases were all in families under frequent observation, for all of whom I practiced. From statements made to me by habitués themselves I am satisfied that the sexual appetite is not destroyed; in one case, a young man of 25 years, whose grandfather was a drunkard, his grandmother a neurotic, his father a user to excess of both whisky and morphin—dying finally from the effects of the opiate—and his mother ending her days at about forty years in the same way, the sexual appetite is claimed to be as vigorous as ever, while he uses not less than twenty grains of morphin, hypodermically, every day. Where the father is a user of morphin the children begotten have not been many in a family. In the case of the mother, abortions have seemed to me to be more frequent; and where the children have been brought at full term, I have found many cases in which the children have died cyanosed from non-closure of the foramen ovale. In the case of one mother, one child was born, which within forty-eight hours became restless and cyanotic, and in spite of simple remedies, died before the end of the third day. At that time I did not know that she was a morphin user. Two years later another child was born, which in every respect duplicated the history of the preceding one. About two years later a third was born, which died as did the first and second. The mother at the time was using increasing doses of morphin. Two years later, a fourth child was born, which showed all the effects of morphin that the three before it had, but knowing at that time that the mother was using two drams of morphin a week—about seventeen grains a day—I began the administration of full doses of paregoric to the infant, and after gradually increasing the doses to about twenty drops every three hours, I found a steady improvement; the cyanosis disappeared on the fifth or sixth day, and after one month I was able to discontinue the use of the opiate. At no time was the child quiet during that period, except when under the influence of the drug. The digestion of the child was poor, and it had an aged, withered, pinched look. At the age of five months it died. In another case, a mother with no hereditary taint, with an excellent family history, suffered from periodic attacks of sick-headache. She had menstruated scantily all her life. She gave birth to a vigorous, healthy boy, who at the age of 18 years is strong mentally and physically. Between the birth of this one and the second child, she began using morphin, though not in large doses; but she was constantly under the influence of the drug during the whole time of the second pregnancy. The child was born at full term, but had an aged appearance, was nervous, restless and fretful, with, at times, cyanotic attacks. Dover's powder in half-grain doses was given every two hours; then on the second day it was increased to one grain, and repeated *pro re nata*. The babe became quiet; cyanosis gradually decreased, and the opiate was then diminished. The child is now living, and at the age of 12 years is not as large as he should be at 8 or 9, nor is he vigorous otherwise, physically or mentally. This same mother gave birth two years afterward to a female child at full term; and again, two years later, to another female, both of which died with every symptom of an open foramen ovale. This mother is still living, but has not been pregnant for eight years; she still uses morphin, but not in increasing doses. She has always denied any sexual appetite.

MORPHIN RETARDS DEVELOPMENT.

I have been persuaded, in reviewing the work of my earlier life, that in many of these cases of death among infants where no reason could be assigned for them, the opium curse accounts for the trouble. The rationale of the non-closure of the foramen ovale in such children is easily understood. We know that opium in any of its forms delays all changes in the human economy, and hence in the pregnant woman who is a morphin habitué, the nutrition furnished the child in utero is vitiated by the drug; the full and perfect development of the fetus is delayed, and at the last moment labor begins before the closure of the foramen has been properly advanced, hence the child's circulation after birth is the same as that in utero, and cyanosis follows, because a proper supply of oxygen is not furnished the blood, as it should be during respiration, the blood being diverted by the open foramen in the direction of the fetal circulation. If the child be kept alive for a few days, by careful management, the foramen closes and cyanosis ceases. To keep this child alive, it is necessary, as has been shown frequently, to give it some one of the many preparations of opium, gradually reducing the dose until the drug-habit has been eradicated.

FIRST DOSE PRODUCING HABIT.

In some cases it has been clearly and conclusively shown that with the first dose of the narcotic, the child becomes a confirmed opium-taker. Such a case has been reported by Dr. Crothers, and I have had a similar experience with a patient who is now using twenty grains of morphin per day. This person did not get his first dose until he was several years old, and from the time that was administered, he reports that he has not been able to restrain his desire for the drug. One forcible detention for a few weeks in a "Cure," and several efforts to withdraw the drug gradually, have proved complete failures. He now reports that he has no desire to leave off the drug, yet he knows that both his father and mother ended their days as confirmed users of it. He calls the drug his medicine, and he believes that he can deceive even the elect in regard to his using it. I have never yet seen a confirmed opium user whose assertion could be depended on in regard to anything.

CYANOSIS AND MORPHIN.

Returning again to the question of cyanosis, I desire to impress one point, learned from experience drawn from many cases of children born of morphin-using mothers, viz., that when an infant that has been unusually quiet, resting sweetly, reported by mother and nurse as a "good baby," for from twelve to twenty-four hours, begins to fret and grow restless without any apparent cause, and when, in addition, the nurse reports the child as "looking blue," then it becomes important to inquire into the family history of the child. Not only should inquiry be made of the mother, but of the nurse and father. Then, if no light can be gained in the matter, the mother should be watched. If the drug is used it can soon be determined. She can not do without it after labor, and if deprived of it, the after-pains may cause, as they did in one of my cases, puerperal convulsions. In this case the mother died before she could be gotten under the influence of the drug, of which she had been using seventeen grains a day. The child was saved by administering opiates and afterward gradually withdrawing them.

CURE BY GRADUAL WITHDRAWAL.

Another point has been established in the work of the general practitioner, viz., that if a patient honestly desires to abandon the morphin habit, it can be gradually withdrawn without much discomfort to the patient, sometimes with the aid of some substitute for the morphin, such as papain, and sometimes by means of the gradual withdrawal of the morphin, substituting enough of strychnia, as the morphin is lessened, to stimulate the patient to the point that the "gone feeling" does not develop.

In another case, where I found a prisoner using thirty grains of morphin *per os* a day. I had no trouble in rapidly reducing the dose, beginning with eight grains morning and night, combining each dose with five grains of quinin, and leaving off one grain of morphin out of each dose every day. The patient never suspected the reduction until the dose reached one grain twice a day, but no nervous symptoms supervened until the dose was reduced to one-eighth grain twice a day. Then, discovering what had been done, he became unruly, but in three days the storm had passed and the appetite disappeared. We have all found that those who use morphin hypodermically on themselves, are managed and reformed with more difficulty than are those who use the drug *per os.* I have had one patient who abandoned the hypodermic use of morphin, which she had kept up for years, by substituting, *per os,* some patent preparation of opium. She seemed to suffer not at all while withdrawing and decreasing the hypodermic. I would by no means advocate the home treatment of morphin habitués, except for such cases as are sometimes met with where the patient must either continue a slave to his or her appetite, or be treated at home. The habit can be eradicated much more rapidly under changed surroundings than it is possible to do at home, where everything brings the morphin habit so forcibly before the patient.

MANY PHYSICIANS ACQUIRE THE HABIT.

On still another point I am prepared to go on record authoritatively in regard to morphinism. In glancing over some records in my office I find, in a list of the names of one hundred and fourteen physicians, almost all of whom have been personally known to me, eighteen who became addicted to morphin—nearly 16 per cent.—five who used whisky to excess—three of them dying of chronic alcoholism, and three who became addicted to the excessive use of chloroform, one of the three inhaling it to stupefaction as a substitute for whisky, and all three dying from its effect. These records show that twenty-three, or about 20 per cent., were unfitted for the practice of medicine by reason of their habits.

MORPHINISM AND HEREDITY.

As to the question of heredity in its relation to morphinism, my own observations are fully in accord with those of many other writers on the subject. The morphin habit is not transmitted, except in the few rare cases already referred to, where the offspring of the morphin-using mother demands the drug from its birth to preserve its life; but a certain dyscrasia, or peculiar state of the nervous system, results that in the course of time demands either alcohol or opium, and when the first portion of either is taken, the ruin and wreck has begun. In the family of a morphin-eating, whisky-drinking physician, I have seen one son die a perfect wreck from the use of both these drugs, and another son worse than dead, a vagabond upon the face of the earth. In this family the mother had no bad habits, was unusually bright mentally, and her characteristics, both mental and physical, were transmitted to the girls. In another physician's family a son and daughter have developed the morphin habit. In another, where alcohol was the curse, one son is a wreck. In two patients, not physicians, the children born to them—one father being a morphin habitué, the other an alcoholic—have no mental acumen. In another family where for three generations whisky and morphin were both used, the third generation is almost extinct, without offspring; the one representative has never used either drug, but suffers for the sins of his ancestors.

Our almshouses and asylums are being rapidly filled with degenerates; even in our country counties and towns, where many of the vices of "higher civilization" such as syphilis, sexual debauchery, etc., are unknown, and where the history of the case can be traced without doubt to the excessive use of some of the derivations of morphin. Whisky has slain its thousands, but a vice of a greater magnitude, because it can for a long time be indulged in secretly, and one that is seizing hold upon the mothers and daughters of the day, will have to be faced and fought in the twentieth century. We as physicians owe it to the nation to keep this subject plainly before the people.

MEDICOLEGAL RELATIONS OF OPIUM INEBRIETY AND THE NECESSITY FOR LEGAL RECOGNITION.*

T. D. CROTHERS, M.D.
HARTFORD, CONN.

How far is a morphia or opium habitué responsible for his acts? Will the use of opium or other narcotic drugs diminish or destroy the sense of right and wrong, or of duty and obligation? Will opium and allied drugs whose physiologic action is most prominent on the sensory centers disturb the reason and the higher moral centers and encourage crime and criminal acts? Practically the opium inebriate is uniformly untruthful, particularly regarding himself and his use of drugs. Like the alcoholic, when under the influence of drugs he resorts to intrigue and deception, often coarsely or skilfully executed. Thus secrecy, deception and disregard of all questions of ethics and duty are the common symptoms. Obligations of honor and respect for society and for those having claims upon him have little influence compared with his morbid impulses and feelings.

---

*Presented to the Section on Nervous and Mental Diseases, at the Fifty-first Annual Meeting of the American Medical Association, held at Atlantic City, N. J., June 5-8, 1900.

In some instances in the earlier stages but little change is apparent in the higher brain function, but when subjected to pressure or strain of temptation the real condition appears in weakness and failure, which was unsuspected before.

CHARACTER OF CRIMES COMMITTED BY THE HABITUE.

The action of opium on the brain and nervous system is that of a narcotic and depressant, hence crimes of violence are rarely committed. Crimes against property and character, and crimes associated with selfishness, scepticism and credulity are more common. Some of the illustrative incidents of these classes are the disinheriting of the only son in a will because he has incurred his father's displeasure. Another man forges a note to procure money for opium. Another enacts a scheme to defraud his father. In another case a swindling operattion is engaged in. In still another a printer goes about the country marrying in every town that he lives in, disappearing in a short time, changing his name, and seeking new acquaintances for the purpose of marrying again. These are crimes of selfishness and impulse, and are often associated with cunning and design, but they lack the essential features of calculating criminals.

WHY MORPHINISTS ARE IRRESPONSIBLE.

There are many physiologic reasons for the assertion that opium inebriates are irresponsible for their acts. Continuous narcotism and blunting of the sensory centers impair the power of reasoning, by obscuring and narrowing the impressions of the senses. The opium inebriate has always diminished and deranged powers of seeing, hearing, taste and smell. The objective world is not correctly seen. The subjective functions of the brain and nervous system are slowed up and their activity and acuteness lessened. In addition to this the waste products are increased, and the power of elimination is retarded. Favorable soils are formed for the growth of toxins and poisons which in themselves are sources of depression. Anemia and disturbed nutrition are common symptoms of this condition. It would be impossible for such persons to have a clear recognition of the nature and consequence of acts and conduct. Practically, persons suffering in this way act automatically, repeating what has been done before, showing some recognition of duty and obligation, but if confronted with a new set of facts and new conditions, would be unable to recognize the relations of right and wrong. All opium inebriates are controlled by the impulse to procure and to use the drug at such times as they may think best for their comfort, and every consideration must be subservient to this impulse. The comfort or discomfort which comes from the use or absence of the drug is always attributed to objective conditions, hence, the reason is perverted and sense activities are deranged. Pessimism associated with egotism grows so rapidly that the relations, both of the subjective and objective conditions and events, are confused and misunderstood. Where the quality and nature of conduct and acts come into question this defect is very apparent if along unaccustomed lines of thought and action; and often it will vary widely with the physiologic condition of the person and of his surroundings.

LEGAL RESPONSIBILITY IN DISPOSITION OF PROPERTY.

Recently these questions of responsibility have come into prominence concerning the disposition of property by persons who use opium.

A recent instance is that of a merchant who had used morphia for five years, and was forced by persuasion of his sons to undergo treatment in an asylum; he made a will disinheriting them. He urged that he could recover at home, and that it was a hardship to go away under special treatment. The morphia was withdrawn, and he returned apparently cheerful, and continued in former pleasant relations with his sons. One year later he died from an accident, and a will was found giving all of his property to his daughters. This will was drawn up after the return from the sanitarium, when he was not using morphia, and was apparently in full possession of his senses. He explained to the lawyer who drew the will that this disposition had been resolved on for a long time and grew out of want of confidence in his sons. In a careful study of the case I found that morphia had been given for insomnia and neurasthenic states some years before and had been continued in increasing doses up to the time of entrance into an asylum. Soon after he began to use morphia, mild delusions of losing his property and fears of loss by fire and burglars grew constantly. At times he was excited because unusual efforts were not made to avoid these dangers. After returning from the asylum he was more irritable and depressed than ever. The strong probability was that he began the use of morphia again although this was concealed. His delusional egotism and continued denial of using the drug when it was in his possession were prominent symptoms. From this and other facts I was convinced of his irresponsibility and mental perversion at the time of writing his will. The result was a settlement out of court.

Example 2.—A morphinomaniac who began the use of morphia eight years before for relief from neuralgia following an attack of malaria, continued the doses, gradually increasing them until he was using twenty grains a day. Except occasional somnolence and short periods of excitement, he seemed in no way changed. Suddenly, without cause, he sold out his business and property to a clerk for a very low price. His family applied for a guardian, and a commission was appointed to examine him. His changed mentality and extraordinary care of his business at times, followed by periods of great excitement or indifference and disregard of any business considerations, were the most prominent symptoms. He had delusions and fear of violent death, and would not ride in a public conveyance. He thought his family was opposed to him and wished to have him die. At times he was very credulous and emotionally religious; then he would become skeptical of everything and doubt every statement made. The commission decided that his mind was impaired to the extent of being unable to judge of his property and of his relations to his family.

These examples are given to show that in the care and disposition of property an opium eater is most likely to have an impaired mind and mentality, and is unable to reason sanely and to understand the relations and duties to others. His impressions are unstable and his reasoning changeable; hence he is not likely to act consistently or rationally.

RESPONSIBILITY IN SWINDLING AND FRAUD.

In criminal acts the morphinist and opium-taker is often seen in swindling operations, deception and frauds. A very few cases have been contested on the ground of irresponsibility of the criminal. In most of these cases the facts of the history were not studied with sufficient minuteness, and the court preferred not to enter upon the fine distinctions or to permit innovations in the ordinary rulings. One such case preferred to go to prison rather than to have a defense made on the ground of opium-taking. The circumstances were these:

A manufacturer, 54 years old, in good health, and of excellent character, was given opium for some digestive troubles. The effect was so pleasing that its withdrawal was followed by insomnia, and hence opium was continued. It was changed to morphia, which was used by the needle secretly. Six years after, he was tried and sentenced to prison for forgery. He had used the names of his friends on bank notes, and became involved, although not bankrupt. The forgery was unreasonable, and without special motive or purpose, and wanting in the usual cunning of this class of crime. His embarrassment could have been relieved without resorting to this crime. For two years he had forged papers and notes, taking them up before the forgery was found out. He was not a poor man and did not seem to make anything by these efforts. He could not explain why he had done this, and did not seem to realize the nature of the act, but excused it in a childish way as "business methods." His mind was feeble and he manifested religious delusions, carrying on a correspondence with relatives who were dead. To his family he was reticent and suspicious, rarely irritable but always melancholy. There was unquestionably mental impairment in this case, and a degree of insanity which was not recognized. The man is now serving out his sentence, his mind seriously affected. Had he been sent to an insane asylum and properly treated, there might have been recovery.

RESPONSIBILITY FOR EXTREME SELFISHNESS.

Other cases of opium inebriety exhibit symptoms of intense selfishness which merge into dishonesty and crime. Often such persons show a veritable delirium of acquisitiveness. Their relations to others are those of grasping selfishness and contant efforts to borrow, beg, and appropriate everything of value which may or may not add to the comfort of the individual. Such persons are always slanderous, deceitful, and untruthful. They commit crimes of minor character and show extraordinary ability in denial and explanations of their conduct.

Recently, a morphinist of several years' indulgence died. An inventory of his property showed a large collection of miscellaneous articles which had been both borrowed and stolen. An effort was made in the courts to identify these goods and to distribute them to the rightful owners. It was found that for years he constantly begged, borrowed and finally stole, everything he fancied. The foremost thought of his mind was to procure something for nothing. He was shunned by his neighbors and friends, and on several occasions was arrested, but was always able to prove an alibi. There seemed to be no object in life except to procure morphia and to go about gathering up things. He seemed to possess cunning enough not to steal openly or to go about at night, and when confronted with his theft always explained that it was borrowed, to be returned at a certain time. This mania was a degree of irresponsibility which should have been recognized as clearly as if it had been homicidal. He possessed a certain amount of intellectual capacity, talking about events outside of himself, and showing a perception of the relation of the surroundings and conditions common to ordinary men.

It is not intended to imply that this peculiar symptom of delirious selfishness is of itself insanity, but when it springs up associated with the excessive use of opium it may naturally be regarded as evidence of irresponsibility. In all these cases there may be surface indications of sanity which may be purely automatic, associated with defects of reasoning and sensory impression, which will not bear the test of critical study.

REPRESENTING TWO TOTALLY DIFFERENT CHARACTERS.

In a paper read before this section last year I pointed out a form of crime following morphia-taking, which apparently had for its object the representation of two different characters. In such instances the leading desire is to be recognized as an honest, innocent man, and at the same time act out the part of an adroit swindler. Under the influence of morphia, both these parts were acted with skill and a degree of judgment. When the morphia was withdrawn singular confusion and childishness would appear. These cases are called by detectives the most adroit and dangerous because of their low cunning, audacity, and utter absence of all consciousness of right and wrong.

PETTY, STEALTHY CRIMINAL ACTS.

Another class is becoming more apparent, whose petty criminal acts are confined to thefts, perjury, and disgraceful conduct. The shop-lifters and the sneak thieves who seldom do anything boldly, who study to keep up the appearance of honesty, but always fail with every temptation and opportunity, are common examples. Many seem to lack the boldness of criminals, but excel them in deception and duplicity. A certain number of these cases are recognized by their friends and are sent to asylums for treatment. The withdrawal of the morphia reveals their real condition, and their constant intrigue and slanderous conduct make them very difficult patients.

CAN THE OPIUM INEBRIATE BE TRUSTED AS A WITNESS?

The question has been asked and answered differently in several important suits, namely, how far can an opium inebriate be trusted as a witness in matters in which he has or has not an interest. I think there can be no question that all statements of such persons on the stand should be considered worthless, unless confirmed by other facts and strong circumstantial evidence. In a recent case an opium-taking woman swore to an assault which she witnessed. In reality, no assault took place. Her statement was either a misconception or a wilful perjury. In another case an opium-taking lawyer swore that he had witnessed a certain will. It subsequently appeared that the will was written and witnessed a long time before. In criminal cases the question of the reliability of the witness is often very important, but the fact of taking opium should always increase the supposition of the possibility of error. The opinion held in courts at present is that the use of opium in any form does not impair the degree of responsibility unless the drug has been used a long time, and stages of chronicity have been reached. It is also asserted that the opium-eater is responsible except at periods when the opium is removed and the mind is in a state of delirium and intense irritation due to this cause. While crime may not be committed during this latter stage, there are always phases of insanity and delirium which can not be mistaken showing the irresponsibility of the acts. The conduct during this period is so clearly that of insanity that no question or doubt can be raised. In disputed cases it is a reasonable procedure to show that the criminal was not using opium at the time the crime was committed, or was not in a condition of opium delirium owing to its withdrawal, but was in a state of opium saturation. In all these conditions, the principal fact that opium had been used a long time previously would be good reason for inferring mental change and unconsciousness of the nature of conduct and acts. The fact should be recognized that the use of opium either in large or small doses for a long or a short time, depending upon the man and his condition always changes and alters the reasoning powers and sensory activities, and is always followed by intellectual weakness with diminished moral sense and consciousness of right and wrong. In many instances this disability is very prominent and apparent from the early use of opium. In all cases this damage to the higher brain centers is persistent and progressive. In some instances it is precipitate and intense. In others it is slow and concealed. In one case under my care a man who was previously of a good character suddenly dropped to very low levels of intrigue and moral paralysis; both his talk and conduct showed marked irresponsibility. This damage from morphia appeared within a year from the time of the first use, indicating both accumulative and concentrative action on the higher brain centers. His intellect in other respects was not much changed. In the case of a printer who was a bigamist, marrying with every opportunity, the injury from morphia was manifest in the same direction. His mind and body seemed not to suffer much change, the insanity of his case developing in this direction. In a noted case of the abduction of a child, the criminal was a morphinist, and the crime was without motive or purpose. Most opium cases coming under legal notice show defects of both reasoning and consciousness, which are usualy concealed by egotism and delusions of free will and power to do differently.

THE CLINICAL HISTORY IMPORTANT.

Wherever the fact of opium appears in a disputed case, the most careful investigation should be given to the clinical history. The first condition and circumstances in which the drug was used will often throw great light on the direction of the degeneration and the pathologic changes which are most active from its use. After the drug has been used a long time, certain local injuries and impairments of functions are always present. From this general study the progressive march down through successive stages is noted by certain localized disabilities and dissolutions, bringing out the fact of irresponsibility without question. Such a study will aways dispel the common delusion that opium-takers are not injured but are responsible and perfectly sane in thought and conduct. It will also clear up the mystery which has gathered about cases where frequent narcosis is produced without the appearance of any serious damage. Crimes and questionable acts by narcotic habitués are always open to suspicion and in most cases the certainty of coming from disease and diseased brains.

The question in most cases whether these perversions and changes are indications of permanent organic changes can only be settled by an appeal to the clinical facts which may be gathered with the same accuracy as those of any other disease. It is perfectly clear that opium-takers should be classed among the insane, and morphinism should be studied as a member of that family of diseases. It is also absolutely clear that all use of opium or of other narcotics is followed by organic change and limited responsibility and impaired degree of health.

NEED OF MEDICOLEGAL STUDY OF MORPHINISM.

The necessity of legal recognition and study of these disputed cases is growing more urgent every year. Questions of partial or total irresponsibility, and failures to realize right and wrong are coming into prominence constantly. When alcohol is used alternately with opium the complexity of the symptoms increases. In reality the degree of unsoundness also increases, and with it irresponsibility, until it is doubtful if anyone can use both long and be sane and rational. The use of opium alone may be continued some time without attracting attention or creating suspicion of mental change. The following cases show that the use of opium was unknown before the commission of crime. A woman killed her infant child and was unable to recall or explain the motive for the act. She became a maniac soon after conviction and sentence to prison. It was found that she was a secret opium-taker and committed the crime in some delusional stage after a larger dose of the drug than usual. A man convicted of incendiarism proved to be a morphia-taker. In prison he suffered from collapse following the withdrawing of the drug, and became insane. He had a mania for the use of morphia, also to set fire to property, and concealed his acts. In another case a man suddenly traded his property for mining stock which was worthless, thus impoverishing his family. An examination revealed the fact that he was a secret opium-taker and had for years committed strange acts. In another case a man invested all his property in a machine for perpetual motion. He was a morphinist, and his use of the drug became known after this event. Another case of a man who became an accessory to a murder, was known to use opium, and although strange and eccentric in his conduct, was considered to be sane. He had been using opium for years and never manifested any violent symptoms, although associating with low company much of the time. A leading specialist swore that he was sane and responsible for his acts and conduct. It is difficult to understand how any one can use opium and be continually narcotized even in a slight degree and retain health and mental integrity. An examination of such persons shows that they are largely neurotics and degenerates. Many of them have inherited states of nerve and brain exhaustion, and from neglect and bad living have injured the brain and nervous system; such persons have defects, with feeble and unstable brain centers, and the use of opium increases and intensifies this instability. In all the disputed cases which have come under my notice, the first use of opium was found to precede or follow some organic and functional change. These departures from health might have gone on to serious disease in some other direction, but from opium they became concealed, intensified, and turned in certain definite directions. The fact that it was a most grateful sedative at the start indicated a diathesis and predisposition which was significant of further changes. Given a heredity to exhaustion and prediposition to seek relief from psychical and physical pain, and to this add neurasthenic states and the use of opium for years, and it would be impossible to have a clear rational brain and consciousness of right and wrong. In all such cases strange conduct, unusual erratic acts, uncertain, unstable brain functions, morbid impulses, failures of reason and judgment, and inability to recognize right and wrong, and duty to others, followed by crimes, would be the most common sequelæ. Such cases, if studied with the same critical accuracy as that of typhoid fever, insanity and nerve diseases, would appear as irresponsible beyond the slightest shadow or question. The rule should be to examine these cases, beginning with the commission of the crime and going backward, finding the character and extent of the opium addiction, and its physiologic action on the body and mind, tracing this condition still further back to the first use of the drug, and ascertaining all the causes and circumstances associated with its use and the heredity and predisposed states of ill health and disease, to this add the study of the injuries and physiologic changes which have profoundly affected the vigor and growth of the body.

From all these facts very clear conceptions can be drawn of the capacity or incapacity to realize the higher ethical relations of life. Going beyond this, the psychologic question of to what extent any impairment of the brain has destroyed the knowledge of right and wrong may be studied in the act committed. In all these, authorities and courts will differ, often depending upon the theories of the relation of the mind and body, and also on the facts of the case and their meaning. As medical men, we can never be mistaken in claiming irresponsibility for all these cases where the facts indicate an addiction of long continuance. An almost infinite combination of conditions and circumstances will, of necessity, vary and change the minor conditions of each case, but the general facts will remain true, namely, that the use of opium continuously always impairs the responsibility and consciousness of right and wrong.

The conclusions from this study may be grouped as follows: 1. An increasing number of cases where opium addiction has preceded, and is associated with, crime calls for a medical study with some authoritative legal rulings. 2. Both medical experts and judges hesitate to recognize irresponsibility from opium-taking alone and attempt to explain the phenomena by other theories and conditions. As a result, much confusion and injustice follows. 3. Any general study of these cases brings out the fact of disability, and often the crime itself is purposeless and indicates the disorder of reason and control. 4. The use of opium falls most severely on the higher brain centers of consciousness and right and wrong. The derangement of the senses reacting on the reason still further separates them from sanity and health. 5. There should be no question of the incapacity of opium-takers to execute bills and contracts, or to understand the relations of conduct and duty in all relations of life. This should be asserted theoretically, and a study of the cases will practically sustain it. 6. The medical profession should insist that a degree of insanity and irresponsibility exists in all these cases; then legal recognition will follow. 7. Already in several states legal rulings have been made recognizing a limited and impaired responsibility in certain of these cases. Still the theory prevails that the reason is able to discern the conditions and realize the penalties of failure. 8. The pressing need is for a wider study of the facts of the addiction in these disputed cases. Such a study must be made above all theories, statements or appearances, and entirely from the facts and conditions present. 9. Medicolegally, this is a new field awaiting research, in which the number of cases is constantly increasing and the questions of responsibility and degrees of insanity are submitted to the profession more urgently than ever.

DISCUSSION ON THE PAPERS OF DRS. HAPPEL AND CROTHERS.

Dr. Kenniston—I have had a good deal of experience with insanity, and I agree with what Dr. Crothers has stated, that the prolonged use of opium produces not only a moral but also a mental degeneration. Of course, every one is familiar with the class of cases of Coleridge and de Quincy, and how an opium-eater will lie; and a man who has become a confirmed liar is apt to be sooner or later mentally unsound. I have seen a great deal of mischief caused by the reckless prescription of opium by physicians. Opium is often the lazy physician's remedy. I know of at least six cases who are mental, physical and moral wrecks, because of the prolonged and excessive use of opium.

Dr. W. S. Watson, Fishkill-on-Hudson, N. Y.—I heartily agree with the points made by Dr. Crothers in relation to the action of opium on the higher senses. The drug habit unquestionably favors the production of toxins in the system, and a secondary autointoxication is very frequently indirectly, if not directly, due to the drug habit, consequently, mental diseases are not infrequently due to the use of drugs, such as morphia and the other derivatives of opium. I have met with many instances similar to some of those which he pictures. There is no question that the physician is often responsible for the introduction of this habit.

Dr. T. J. Happel, Trenton, Tenn.—The general practitioner has to bear his burden, but he is not responsible for all of these cases. The teaching upon the effect of this morphin habit is not what it should be. Our people should be impressed with the curse of it. We have many people agitating against the use of liquor, and many clergymen preach against it; but it does seem to me that some of these efforts might be profitably employed in the direction of an extension of public knowledge on this important subject, the dangers from the use of morphin.

Dr. T. D. Crothers, Hartford—The question of the mental capacity of opium-takers has come into prominence during the past few years, and while no leading decisions have been made concerning the responsibility or irresponsibility of users of opium or morphin, there is evidently great confusion in the minds of experts as well as judges concerning the facts. At one time there were two cases in which the capacity to devise large estates was the point of issue. A number of medical men gave conflicting opinions as to the meaning of the facts in the case. The adjudication of both cases was unsatisfactory, due largely to the want of clear apprehension of the mental condition of the testators. I think any careful study of a number of cases will convince the student that morphinism means irresponsibility and diminished ability to distinguish between right and wrong. The constant narcotism which comes from morphia must of necessity impair both the senses and reasoning, and while each case is a law to itself, we must admit impaired mental ability. My aim has been in this paper to bring out this fact and to attempt to rouse greater interest in this subject, which is becoming prominent in courtrooms.

TREATMENT OF MORPHINISM.

THE NECESSITY OF A MORE UNIVERSAL KNOWLEDGE THEREOF: REPORT OF CASES.[*]

A. J. PRESSEY, M.D.
CLEVELAND, OHIO.

The medical profession may be divided into three classes, with reference to their different views of morphinism and its treatment: 1. Those who consider that the addiction has produced a diseased condition of the nerve-centers and that by a well-directed, scientific treatment the patient may be restored to health. 2. Those who believe that the continuous use of morphin produces such a pathologic condition of the nerve-centers that treatment is of no avail, that is, "once in morphin always in morphin." 3. Those who look with little sympathy on those unfortunates who have become accustomed to the use of narcotic drugs, and who seem to consider the use of the hypodermic a mere habit which could be as readily discontinued as could a physician cease toying with his watchchain or mustache while talking at the bedside of his patients. In other words, they think that if the person desires to discontinue the use of the drug, why does he not quit it?

In regard to those in the first division we will say that morphinism has long been known, by those who have given it the most attention, to be a curable disease. Of course, there have been many relapses, after the best known plans of treatment. There always will be some relapses, but these, I believe, will grow less and less as the disease is better understood and treated. There are many other diseases which frequently relapse, but that is not a sufficient reason why they should not receive treatment. I have never heard of a physician refusing to treat a case of appendicitis because of its liability to recur.

---

[*] Presented to the Section on Nervous and Mental Diseases, at the Fifty-first Annual Meeting of the American Medical Association, held at Atlantic City, N. J., June 5-8, 1900.

In regard to the second division, I wish to relate a few experiences. About five years ago a young man came to consult me regarding his case. He was using 60 grains of morphin per day hypodermically. Every portion of his body which he could reach to use the hypodermic was covered with abscesses produced by the needle. I counted fifty on one arm between the shoulder and the wrist. He was in a deplorable condition both mentally and physically. He had been advised that day by a physician to go to the hospital and have the abscesses cured, be taught how to use the hypodermic so as not to make more, and continue to take as small doses as possible, for he could never be cured of the "habit." He, however, decided to take treatment, was finally cured, and three years after was free of morphin; since that time I have not heard from or of him. Four years ago Mrs. N. came to me for treatment, and said she would have been treated two years previously had not her physician told her she could not be cured. She decided to make the effort, took treatment and was cured, and I believe she is yet free of the addiction. Mrs. D., who had arrangements nearly completed to come to my place for treatment, received a voluntary visit from her family physician urging her not to attempt treatment, and stating that she could never be free from the use of opiates and that she had better continue their use. However, after further correspondence, she came, took treatment, and was cured. Mrs. B., a widow who is at the time of writing this paper under treatment, came to me a physical wreck, using 20 grains of morphin per day hypodermically. She was very much emaciated; her appetite was very poor, digestion bad, bowels very much constipated; she got little sleep, and was compelled to stay in bed one or two days every week on account of headache. Her physician, who was formerly a partner of her husband and is now a personal friend of hers, urged that she could not be cured. She is now using only 1 grain per day. She has increased in weight eight pounds. Her appetite is good; she sleeps well; the digestion is improved; the bowels are in better condition, and she has had no headaches in several weeks.

I might recite many other cases, but the above are sufficient to show that at the present time there are some physicians who do not believe in treatment of morphinism. This condition can be only detrimental to the physician and doubly so to patients, for there is no doubt that many patients are discouraged from taking treatment and continue in the most wretched condition, when with better advice they might be restored to health and useful lives.

The third class, or those who look upon the addiction as a mere habit, probably have seen little or nothing of the abstinence symptoms which follow within thirty-six hours of the time that abstinence begins, such as vomiting, diarrhea, cramps in the legs, arms and abdomen, profuse perspiration, extreme nervousness that is varied and indescribable, prostration with possibly collapse and death. It would seem from a physician's knowledge of opiates that he should be able to reason that the long-continued use of so virulent a narcotic poison as morphin in doses sufficiently large to produce the death of fifteen or twenty persons not accustomed to the use of the drug, must of necessity have produced some pathologic change in the nerve-centers. Any change from the normal must mean disease. A diseased condition is entitled to our consideration and to treatment.

I now wish to give a very brief report of some cases for the purpose of demonstrating what I have previously said.

In November, 1899, a physician in the city of Cleveland called on me and requested that I would visit his friend, a Dr. R., who had been using morphin about nine years and who had been making heroic efforts for the past six months to discontinue the use of the drug. The next day I called at the residence of Dr. R. and found that he had ceased all business for several months, giving his undivided attention to freeing himself of the morphin addiction. He was much emaciated, very weak and nervous, so much so that it required considerable effort for him to articulate distinctly. His condition would suggest complete nervous prostration. He had reduced his dose from about 20 to 25 grains per day to not more than 1 grain per day. I was unable at that time to induce him to accept any assistance in the way of treatment. He was thoroughly convinced that no system of treatment could be of any assistance for the relief of morphinism, and that the only thing was to stop taking the drug. He appeared firmly to believe that he would be able to do it within the next very few days, as he had already reduced his dose to so small an amount. He came to me for treatment about four weeks later, at which time he had increased the quantity used in twenty-four hours to about 3 grains. He was discharged cured in nine weeks. There was scarcely a day while under treatment that he did not express regret at having refused the advice of some of his friends and placed himself where he could have received the assistance necessary to restore him to health.

Mrs. D., whom I have before mentioned, came to me for treatment in the autumn of 1898. Her age was 40. She had used laudanum for seventeen years; her general health was poor; she was very nervous and irritable; she had very little appetite. However, she was able to accomplish considerable labor about the home when she used plenty of opium. She had been a woman of uncommon energy and determination. Although her family physician had advised both her and her husband, that in her feeble health, at her age and because she had used opium for so many years, it would be impossible for her to stand the suffering she would be obliged to endure to be cured of morphinism, and that as she could yet attend to many of her household duties, by continuing the use of opiates she might live in some degree of comfort for several years to come. Although this advice had a somewhat discouraging influence over her, her great desire to be free of the addiction finally decided her to at least make the effort. In her case the opiates were withdrawn very gradually, at no time to the extent of causing diarrhea, vomiting, perspiration or pain. With the exception of feeling weak and having a nervous, uneasy sensation of the legs, I think she was fully as comfortable during her entire treatment as when she took laudanum ad libitum. After returning to her home, she continued to improve in strength and flesh, and when the warm spring weather came she lived and worked much of the time out of doors. It is now nearly a year and a half since she discontinued the opiate and her husband informs me that she is in better health than she has been before for twenty years, and that she has no need of any drugs whatever.

A Mr. B. came to me for treatment in the autumn of 1897, aged 40 years, single and much emaciated; he had chronic gastritis; his bowels were constipated; he was very despondent. He said that he had been told so many times by physicians that he could not live without some opiate, that he had little faith himself in ever getting free of it. He had used opiates sixteen years and was using 60 grains of morphin hypodermically and drinking 2 quarts of whisky during each twenty-four hours when he came to me. I withdrew the whisky within the first few days. I was between three and four months withdrawing the morphin. He remained in bed quite a large portion of the first part of his treatment. As soon as the stomach would tolerate food he was encouraged to eat all that he could of an easily digested and nutritious diet. I gave nerve, heart and general tonics, hot baths and massage. The withdrawal was so gradual that at no time was there any indication of the ordinary withdrawal symptoms. He remained with me for several weeks after taking the last dose of morphin. He left me, feeling well and strong, and I am very sure that he has never tasted liquor or used morphin since leaving my place, now over two years. His was a most desperate case, but, as is usual with a large majority of this class of cases, when they are entirely free of the necessity of the drug they recuperate very rapidly and very soon seem to attain to their full physical and mental capabilities.

There are without question large numbers of persons addicted to the use of opiates, and where physicians have not the conveniences and necessary time to give to the treatment of these cases they should be sent where they may receive proper care and treatment. We should remember that, while some of the milder cases will relapse, some of those who appear the most hopeless will remain faithful to the end, and they will become good members of society, a comfort to their families, and to themselves life will be worth the living.

In fact, I know of no disease or class of diseases for which the physician's aid is sought more satisfactory to treat, or of which the patient is more grateful to be relieved than morphinism.

900 Fairmount Street.

DISCUSSION.

Dr. D. T. Millspaugh, Paterson, N. J.—I wish emphatically to indorse Dr. Pressey's opinion that morphin addiction is a disease and a curable one. To those so afflicted, who are in the very depths of despair and hopelessness and ill-health, the benefits to be derived from a scientific treatment that reaches their case can not be overestimated. I would like particularly to ask Dr. Pressey what he uses to stimulate the heart, if he has any specific drug or treatment for that purpose?

Dr. H. H. Levy, Richmond—What is the meaning of the cure of the morphia habit? When do we know that we have cured a patient? I would say that in my limited experience I have seen cases which were apparently cured, in three years take up the habit again. They always allege that there is some special or unusual strain or reason why they did it, and that brings up another question: What are the causes of the original taking of morphin? How is the habit begun? That is important to the general practitioner. Are we responsible for the beginning of such a habit by the administration of an occasional dose of morphin for the relief of pain? Practically, I think we all know that we can give an opiate to a hundred patients and in one only may the habit be engendered. Has one dose of an opiate administered for the relief of pain been the true cause of this habit? My idea is, and I do not believe that I stand alone, that there is some precedent deficiency in the nervous system; that there is some lack of full strength or of control, or, we might say, an inherent weakness in the nerve cells of the brain which calls for bracing up and stimulation. I have in a few cases been able to go back to the early history of drug habitués, and have always found something occurring in childhood, for example, some long, protracted illness, which has weakened the system; and along with other organs and tissues of the body, the nervous system has suffered some detriment. I believe it is either heredity or an early acquired condition of the nervous system that leads up to the formation of this habit. Such a subject never having been called upon to take an opiate may never have started the habit, but the administration of a single dose may cause the habit to be engendered.

I desire now to allude to the treatment in Keeley institutes of morphia and cocain habitués.

If we can endorse the results obtained in the liquor habit by that system of treatment, I believe we should every one of us inveigh against its application to morphia habitués. I have, within a few months, known of two physicians, subjects of the habit, submitting themselves to treatment in a Keeley institute, and one of them made a very rapid improvement, getting completely rid of morphia; but three weeks later he was again taking the drug. It seems that there is for opium and cocain takers only the most transient help afforded by the Keeley treatment, and I think we should dissuade our patients from taking it.

Dr. Dunham, New York—I am very much pleased with the Section. There is a field for workers in this line, and the field is not entirely outside the medical profession. Morphinism is a disease which can be cured. If they relapse, cure again. I would treat them like tonsillitis. It is possible to treat them if the general health improves after treatment. I want to report one case which is interesting, and it may help others who have had experience in the same line. It was a case of morphinism following headache for ten years. We prescribed hyoscin hydrobromate, 1/150-grain dose. This being a neurotic case, it did relapse in a year; she took it again and then relief came. She then relapsed the second time, and then remained well. I want to make another addition here, that is, disease of the brain leading to the use of a narcotic, such as morphin and liquor, and so in addition to the morphin we have a symptom of a diseased condition. We can remove the disease all very well. I offer to the Section this morning this hyoscin hydrobromate as a remedy which is valuable in all of those cases where there is a great neurotic element. They do not get using it themselves; it is really in the hands of the physician and is perfectly safe.

Dr. Campbell, New York—My experience has been quite extensive. I decidedly claim that morphinism is never cured, a person with the morphin habit, if we take the words of our old teacher, Dr. ——. He says that the morphin habit is never cured, and that a person who takes morphin for work can never be relied on. It is the history of criminal cases, that a morphin fiend will lie to physician, husband, wife, child and father; you can never depend on the word of one who has the morphin habit. In my experience in the city of New York, where I have seen physicians bring these morphin-habit people, I could not point my finger to one who has been cured. I have seen them cured of the whisky habit by taking the Keeley cure, and I have seen people two or three years out of the Keeley Institute with the morphin habit. I have had experience with doctors who have taken the Keeley cure, and if we could take these doctors and break their hypodermic syringes up, remove the morphin temptation, we would not have them go back for some time. Right in my neighborhood in New York to-day there are eminent men who have themselves dosed with morphin all the time and they have been in the Keeley Institute for this habit. I claim—I am sorry— I have never seen a case of morphinism cured. I am connected with the "Tombs," where we have them every day. There is not a day in the year but there are people to whom I have to give morphin. I could cure them by "stocking" them. It is impossible to keep them there without giving them some, as high as three grains a day. I would like very much to hear the Doctor's cure.

Dr. F. S. Pearce, Philadelphia—I believe that there is a large amount of truth in what the Doctor says. I think he sees a class of morphin cases associated with degeneracy in a mild or great measure; and in those people, of course, you can not expect good results.

In private practice you will see good and bad; you will treat more of the normal type of human body. I myself in a short experience have seen four or five cases of morphia habit cured, and they have not relapsed. While we all grant that morphinomania is most difficult to treat, I feel that in an institution you get a class of cases that are on the wrong side of the fence—degenerates. This sad fact should not at all prevent us from doing our utmost toward saving the others, of whom I feel positive there are a great many more than physician or layman supposes.

Dr. McCarthy, Philadelphia—It strikes me, with regard to the morphin habit, that there are individuals who form habits of any kind. It does not seem that there is connected with these individuals any weakness of will power, but they will form habits from time to time. They will start as children, and even the minor habits of childhood developed will become intensified. When they start using tobacco it is carried to excess, or the liquor habit, or any habit is carried to excess. In some cases there is little evidence to show that they are degenerate, but their ability to form habits. A physician is never justified in giving morphin if he informs the patient that he is getting it. In those cases of morphinism, the patients knew at the time that the doctor was giving morphin, not only that, but other drugs. The patient nowadays knows about as much as the physician does of the drugs he is taking. The patient looks at the prescription and knows all about it. I have made it a practice to tell the patient nothing about the drugs he is taking. As far as working in other drugs, they may be getting the morphin or water habit, but they never know it. I think it is a point of prevention in the morphin habit that a physician is never justified in telling the patient that he is giving the drug in any form whatsoever.

In the cure of these cases the physician regards a case of morphin cured when he stops it and bring the patient down to the point where he is not taking it. The nutrition is very poor, the weight of the individual is below normal, and there is no wonder in these cases that the patients go back to their old habits. The rational treatment is, after the patient is entirely cured, after the morphin is entirely removed, to put him on a systematic course of rest-treatment, a building-up treatment.

Dr. A. J. Pressey, Cleveland—What do I do to stimulate the heart, I am asked. I use strychnin all through the treatment, as a rule. I give small doses, about four times a day, generally, If they need further stimulants for the heart, I prefer nitroglycerin. Digitalin, if continued, causes nausea and disturbs digestion.

What is a cure? A cure for morphinism is exactly what a cure for pneumonia or tonsillitis or any ordinary disease is. When the patient is well and free of the desire for morphin, and no other drugs are required to make him comfortable, he is cured of morphinism. He is as much cured if he should return to the use of it in a month as he would be if he never returned to the use of it. It is not right to say that a person was not cured because he began the use of it again in a month or a year. If you treat a case of pneumonia and the man is well, you would not say he was not cured because he had pneumonia again the next year.

What is the cause of the habit? The causes are many, almost innumerable. Among morphin-users there are many degenerates, persons who seem to require a narcotic to make them feel in a normal condition. If such a person gets a hypodermic of morphin and knows what he has taken, he is very apt to become addicted to the use of it. Very many physicians contract the habit through overwork, or trying to work while suffering physical pain, taking an occasional hypodermic to relieve them in order to be able to continue their work. Patients while suffering from some painful ailment receive some hypodermic and unfortunately find out that it was morphin, and later have other excuses that they may have more morphin. Physicians should never allow patients to know what they are taking, and especially is this true when narcotics are given.

My friend here of the "Tombs," who believes that morphinism is never cured, does not see the favorable class of patients for treatment. Those that appear at the "Tombs" are largely of a degenerate class, and those who have relapsed perhaps repeatedly. No one would expect many, if any, of these could be cured.

As to the reliability of their word, I believe that the majority of the better class of morphin patients will be truthful in regard to all things except the subject of morphin. I believe that I know plenty of persons who use and those who have used morphin whose evidence I would accept in court as soon as that of a person who had never used the drug, but not their word on the subject of morphin.

Then he spoke of curing them by forcing the drug away from them. I have had considerable experience with persons who had been treated in that way, and have never seen a person so treated but soon relapsed. I do not doubt that some have been cured and remained cured, but I do think it is a cruel and inhuman thing to do. Where there is such a violent shock to the nervous system as there must be to produce so severe symptoms as result from sudden withdrawal, nature comes very slowly to the rescue and full recovery is delayed for a long time. I know that many relapse after my treatment. I have one case that I have treated four times. He is a successful physician and does good work, and never relapses until months after he has been cured and at work, and when there seems no excuse whatever for taking morphin.

The treatment must vary according to the conditions of the different patients. While the pathology of morphinism is unknown, we do know that we have a diseased nervous system to deal with, and as we do not know just what that altered condition is, we can not treat it to the best possible advantage, but we can give nerve tonics, try to correct the circulation, and in that way improve nutrition. We know that when the morphin is much reduced the heart becomes very rapid and weak, and that we must support that organ to the best of our ability. Then I try to improve the general health by giving tonics and a good diet. Also, I try to encourage as much sleep as possible. I succeed in keeping my patients in a fairly comfortable condition all the time during treatment by the method I use in reducing the morphin. I have patients come to me taking all the way from 1 to 120 grains of morphin, and in every case—whether taking the smaller or the larger dose—they are taking more than they require to make them comfortable. This surplus I withdraw at once. No one can tell how much that is except as they find out by trying smaller and smaller doses. If I get the dose too small, I increase it until I find the smallest dose that he can use and be nearly comfortable. I then continue him on that dose for one, two, or three days until he has been built up to where he will be very comfortable, then reduce to a smaller dose very gradually. Continue in this way until he is taking so small a dose that he does not know when the last particle is withdrawn. The last amount is seldom larger than 1/120 of a grain, and often much less. I sometimes find patients that I am unable to keep as comfortable as others and reduce them, then I give them a good full dose of morphin, make them perfectly comfortable and afterward put them on a reduced dose for two or three days, or as long as they will tolerate it, then give another full dose, when they can be again reduced. In some cases I have used the rest treatment, sometimes massage, and frequently hot baths.

I find it very difficult to keep patients under treatment as long as they should be after the morphin is withdrawn. A large portion of my patients are physicians, and they are always anxious to get home to their work as soon as possible. No person should go to work until he is well and strong, and has had an opportunity to regain some strength of mind and character. A change of scene and thought would be greatly to their advantage.

SYPHILITIC LOCOLOSIS ALVEOLARIS.*

PYORRHEA ALVEOLARIS.

G. LENOX CURTIS, M. D.
NEW YORK CITY.

For more than twenty years I have given this subject close attention, not only with a view to its cure, but to ascertain the etiology of this disease, which is generally regarded as incurable.

Dr. Farrar says: "I believe locolosis alveolaris is a disease of the peridental membrane aggravated by calcareous deposits on the teeth, which increases the inflammation so greatly that decalcification of the alveolar tissue results, and when this state exists the advance of locolosis increases more rapidly until nature makes a serious effort to expel the tooth, and if successful, the disease subsides and is lost from view. When all the teeth are lost locolosis ceases to be observed, showing that whatever the cause of the socket disease it does not reappear elsewhere."

In an article, "Some Suggestions on the Treatment of Pyorrhea Alveolaris,"[1] published last year, I gave my views in regard to its treatment. I propose now to give some of my views on the causes of this old and destructive disease.

Up to about twelve years ago, I had treated several hundred cases of what I then supposed to be pyorrhea alveolaris. But in the light of our later knowledge I am of the opinion that only recurring cases were worthy of that appellation. At that time I boldly resorted to all methods then in vogue, and freely referred my cases in consultation to those whom—from their writings—I believed to know most on the subject. Degeneracy, due to uric acid, and rheumatism were suggested, and as I found the rheumatic and gouty tendency in patients having the disease I inclined to accept these as causes, if not *the* causes. But later, when the treatment did not effectually suppress the disease, I was satisfied there must be something else behind it all which should be learned. Reviewing the history of many of the most obstinate cases, I found that in several I could trace syphilitic association. Believing much information might be gained I followed this trail and have continued so doing from that time. It was difficult to secure sufficient data, however, by which I could prove scientifically that which I suspected, for, as we all know, syphilis has such an insidious undermining effect, and patients are generally so unwilling to admit facts, that the study has many discouraging aspects. It is, however, my opinion that this disease does not show itself only in those persons who have contracted it, but may also be found in the mother as well as her offspring. It was in these cases that I found locolosis or pyorrhea alveolaris to be so well defined that I felt encouraged. But obstacles arose which retarded my speedily reaching a definite conclusion.

It was my hope at this time that I might gain something by turning these cases over to specialists in syphilis, gout, and rheumatism for treatment, but the varied results led to suspicion, and to caution in speech, until I could get sufficient verified data to act more intelligently. In many cases I found that treatment had not been continued sufficiently to eradicate the specific poison, or the secondary effects thereof.

In 1890 I had an opportunity to study blood, and then it was, that I became convinced that the usual method of its physiologic study was inadequate. I now believe the blood carries with it the active principles of most, if not all, disease. Then the generally accepted plan for the examination of blood was through dry and stained specimens. Even to-day that plan is largely followed. Could any but the most tenacious germs stand the baking process which is claimed to be unavoidable? Not only are such specimens exposed to the oxidizing influence of the atmosphere, but to heat of such a temperature that it is injurious to them. It may be said that only the survival of the fittest can furnish the possible opportunity of study, and then they can be recognized only after a course of staining that decorates them in "war paint," chiefs of their tribe.

Kircher,[2] in 1695, claimed the disease to be due to living organisms, but it was not until 1772 that Lostörfér claimed to be able to distinguish by microscopic examination of the blood, the presence of syphilis and other diseases. In 1890 Watkins, after studying various methods of blood preparation, came to the conclusion and published the fact that there was only one method of scientifically examining the blood, namely, doing it in its fresh state, and before any changes had taken place. He also found that by instantaneous photographing of fresh blood, objects which would otherwise be overlooked were revealed and permanently recorded, showing facts that the dry and stained specimens failed to do.

In 1892 my attention was called to Dr. Watkins' method, and it so favorably impressed me that I have since devoted considerable time to it, and now I am so convinced that it is the only road to an accurate diagnosis of disease, that I am still continuing the accumulation of data, with more or less satisfaction, having for my chief guide a sign in the mouth, which I first observed many years ago, but the importance of which I then failed to appreciate. This sign, which I denominate "egg-skin eschar," I find upon the mucous membrane extending along the ramus and the buccal surface of the gums along the molars. Occasionally it is to be found upon the cheek, near Steno's duct and the angle of the mouth. But I will not dwell upon this point, as I referred to it in the discussion of my article above alluded to.

In the early treatment of this disease, when I found the eschar present, as it was in many cases, I learned to associate it with some obstinate forms. Five years ago I began sending patients to Dr. Robert L. Watkins, of New York City, for blood examination, with the view of ascertaining what existed. This I did without giving Dr. Watkins the history of the case. The examination of more than one hundred cases revealed strong evidences of syphilis, and in every instance when the egg-skin eschar was found the blood showed unmistakable proofs of the taint; in fact, in every case where the blood showed this the egg-skin eschar was present. Dr. Watkins has repeatedly pointed out to me the syphilitic spore. Yet I must admit that the majority of my patients declared that there was no foundation for the suspicion of the disease. But when they received treatment for it they were cured. Although some patients were honest in not knowing the history of their trouble, others did finally remember that they had contracted the disease, and others still acknowledged it at once.

So confident do I feel that my views are correct, that I now treat all cases of this kind with antisyphilitic remedies, and I find that a large percentage of them are beneficial. In several cases I have been misled, and diagnosed suppurative gingivitis as pyorrhea alveolaris. This I did because I could not find the egg-skin eschar, and when the blood was examined and seemed to substantiate my suspicions I refrained from giving specific treatment. To settle the question, I placed several patients suffering from suppurative gingivitis under specific treatment. This caused such unfavorable symptoms that I was soon forced to abandon it. In one case, where the alveolar process on the palatal surface of the teeth was nearly destroyed, and where it was practically in a normal condition on the buccal and labial surfaces, I was puzzled to know why this affection was not general. When septic pulps, salivary calculi and syphilis were excluded I concluded the trouble to be caused by the pressure from a vulcanite plate, to which was attached an artificial velum that had been worn twenty years.

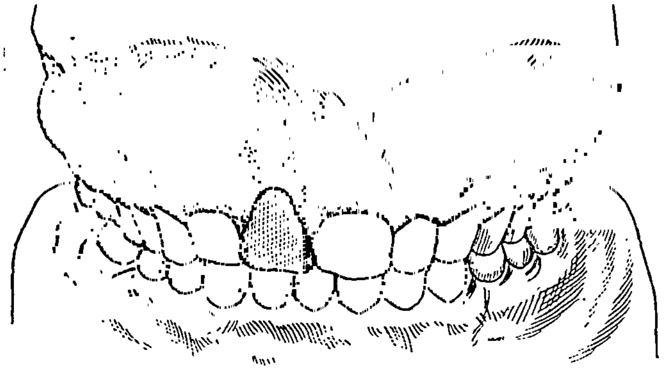
[1] N. Y. Med. Jour., Jan. 14, 1899.

[2] Von Ziemssen: Prac. of Med. vol. III, p. 40.

In another case, the cast of which I have here, the disease was extreme in character. There was great destruction of the interdental process, accompanied by a discharge of pus. Many of the teeth could readily be forced by the finger 1/8 inch farther into the socket. A tumor, osseous in character, extended along nearly the entire length of the alveolar process on the buccal and labial surfaces of the upper alveolar ridge. There was, however, a break in the line of the tumor between the right central and right lateral incisor. The right central incisor had been extracted several years earlier. In this space was an artificial crown, attached to a small bridge-piece, as indicated on the cast.



The cast of the lower jaw showed by the hypertrophied condition of the gum, the extent of the pocket. At first this patient persistently denied ever having syphilis, but the evidence of it was proved by examination of the blood. After I had gained the confidence of the patient, however, he admitted that he had contracted the disease a dozen years before, but had been under treatment for it. He gave as a reason for denying the fact that he did not wish it known to any one except his physician, who had positively stated that he was absolutely cured. The patient now returned to this physician, told him my views as to the cause of the tumefaction, and telling him I said he was still suffering from the taint. The physician made light of the diagnosis, and persuaded the patient not to return to me.

I regret not having an opportunity to finish the treatment of this case, as it would have been an excellent support to my belief that this class of tumors is the result of this dreadful poison.

It is fair to state, however, that within a year the health of the patient so completely failed that he was advised to visit the hot springs for syphilitic treatment.

Where rheumatism is found to be present in a large percentage of cases, I believe it to be a coincidence, though not the cause. I believe that syphilis so reduces the resisting power of the constitution that rheumatism more easily steps in, much the same way that it may while the system is under any degenerating influence. I do not wish it understood that I believe pyorrhea alveolaris exists in every case of syphilis, nor that syphilis is found in every case of pyorrhea. But what I do believe is that some form of syphilis may exist in nearly all obstinate cases of pyorrhea alveolaris that can not otherwise be proved. As proof of the condition I mention, such cases do get well, and remain so when placed under specific treatment until all signs of syphilis cease to appear, not only outwardly, but when the blood fails to show any evidence of it whatever. The value of blood examination, which tells when to commence treatment and when to cease treatment, in this, as in some other diseases, is evident. I also regard it to be of great importance in diagnosing remote causes. Indeed, I predict that the time is not far off when examination of the fresh specimen of the blood will be the principal evidence in proper diagnosis. I have sometimes thought that locolosis or pyorrhea alveolaris may be caused by mercurial poison, but investigation does not bear out this surmise, for I have found this disease where there has been no history of mercury given.

Is it not, therefore, reasonable to conclude that this form of the disease is aggravated, if not caused, by tertiary syphilis?

7 West Fifty-eighth Street.

NEUROTIC AFFECTIONS OF INTERSTITIAL GINGIVITIS.*

J. G. KIERNAN, M.D.

CHICAGO.

The chief function of the nervous system, beside its special function, is that of regulating growth and repair. This function, as Marinesco points out, resides even in the neuron or nerve unit. While this function of regulating growth and repair is often connected with control of the vasomotor system, still, as Collins remarks, there are trophoneuroses in which there are no appreciable vasomotor disturbances, and there are any amount of vasomotor disturbances which are in no sense connected with disturbances of nutrition. The nerves regulating growth and repair are called trophic nerves, and the conditions produced by anomalies of their action are, as already stated, called trophoneuroses. It was in the domain of bone growth that anomalies of the function of the trophic nerves were first observed. Brown-Séquard pointed out certain anomalies in the joints of locomotor ataxics; later similar disturbances were observed in the jaws of patients with this disease. Another great neurosis, paretic dementia, presented similar trophic disturbances, as I pointed out twenty-two years ago.[1] Among these trophoneuroses was one characterized by looseness and falling out of the teeth, alveolar resorption, gingival ulceration and perforation, with, at times, maxillary necrosis. This condition had long been recognized by alienists and neurologists as causing that fall of the teeth which occurs in paretic dementia and locomotor ataxia. As E. S. Talbot[2] remarks, this function of the trophic nerves, however, received but little attention from dentists, albeit its influence has been recognized in dental pathology, in connection with the great neuroses in which gum disorder occurs, followed by loosening of the teeth.

Cases illustrative of this condition have lately been described by Drs. Rawl, Baudet[3] and Chagnon.[4] The case of Dr. Chagnon was that of a man aged 34, who, about ten years previous to coming under his care, had contracted syphilis. Two years later he married and had healthy children. In June, 1895, he was admitted to an insane hospital under intense maniacal excitement, which subsided to give place to the usual symptoms of paretic dementia. The psychosis followed its course without any remarkable incident until about September, 1897. At this time Dr. Chagnon found that the two incisors, the canine, two premolars and the first molar of the left upper maxillary were very loose. The teeth on being picked out were absolutely sound. The ulceration which affected the surface of the alveoli following the loss of the teeth did not heal. About the middle of September a sequestrum, in which the work of alveolar resorption was not much advanced, became detached. The palate roof forming the anterior border of the maxillary sinus was part of the sequestrum. Two months later the ulceration had healed. In June, 1899, when Dr. Chagnon reported this case to the Quebec Medico-Psychologic Society, all the teeth in the lower jaw were sound. The two premolars and the right canine of the upper jaw were decayed. The second and third left molars as well as the first right molar were loose, but perfectly sound. There existed no alveolar pyorrhea; neither did any trace of ulceration appear, except a small opening which would not admit a probe.

Conditions like this may occur not only from constitutional neuroses, but from disturbances of the cranial and spinal nerves as well. They are frequently noticed after injuries to these nerves, but they may also occur as a consequence of the great functional neuroses like epilepsy, neurasthenia and hysteria. Their part in dental pathology is two-fold; they may cause an interstitial gingivitis, which pursues its course without bacterial infection, or they may so weaken the strength of the jaws and gums as to make these into an excellent culture-medium for pyogenic microbes. In dealing, therefore, with the question of treatment, the trophic factor should be taken into consideration, more especially as the structures involved, since they are of a transitory type, are peculiarly liable to its operation.

INTERSTITIAL GINGIVITIS FROM INDIGESTION AUTOINTOXICATION.*

EUGENE S. TALBOT, M. D., D. D. S.

FELLOW OF THE CHICAGO ACADEMY OF MEDICINE
CHICAGO.

In my work upon "Interstitial Gingivitis or So-called Pyorrhea Alveolaris," I divided the etiology into exciting and predisposing, and, again, into local and constitutional causes.

In my article published this year,[1] I discussed one form of the constitutional variety under the heading, "Interstitial Gingivitis Due to Autointoxication." This subject was discussed in a general way. Albu's classification of autointoxication was accepted:

1. Autointoxications from the suppression or disturbance of the functions of an organ, e. g., autointoxication of thyroid gland, pancreas, liver, suprarenal capsules, producing myxedema, diabetes, acute yellow atrophy and Addison's disease. 2. Autointoxications which occur from anomalies in general metabolism without definite localization, such as rheumatism, gout and oxaluria. 3. Autointoxications which are caused by the retention of the physiologic products of metabolism in different organs, such as poisoning due to extensive destruction of the skin by burning, carbolic-acid poisoning, uremia and eclampsia. 4. Autointoxications due to the overproduction of physiologic and pathologic products of the organism, such as ammoniemia, acetonuria, diaceturia, diabetic coma, etc. The most frequent source of this intoxication is the gastrointestinal tract. In this paper I propose to discuss the phase of autointoxication due to indigestion or disturbance of the gastrointestinal tract.

Autointoxication, like all intoxications, comprehends, as W. A. Evans has said: 1, production of the intoxicant; 2, absorption thereof; 3, reaction thereto. These three are embraced when autointoxication is spoken of, which is poisoning of an organism with matter produced by itself. Assimilation, or the making of tissue, is the passing of the simple into the complex, stability into instability, with the storing of the energy. This instability is a necessity of life. Disassimilation, divided into two divisions—death and energy—the last being a modification of death, is the passing of the complex to the simple; the unstable to the stable, with the liberation of the energy.

In the building-up process, the unused portions of the absorbed foods may produce autointoxication. In the breaking-up process, the ash can produce autointoxication. So long as these two processes, tissue-building and tissue-waste, are normal, intoxication can only ensue from faulty action of the destroying organs, of which the liver is the chief, or of the eliminating organs, of which the kidney is a type. This constitutes the first group, those due to faulty elimination. It applies to food-remnants and to tissue-waste, both normal and pathologic.

The second group is due to errors in cell-life. It occurs under three subtypes: 1, by some reason food elements are left unused; 2, the ash from food-burning is unusually toxic or unusually difficult to absorb; 3, the secretion of the cells is toxic.

While it may be stated in accordance with the principles just laid down that, considered from the direct standpoint of the production in the body, there can be no bacteriology of autointoxication; still it must be admitted that it produces culture-mediums in the body which would not otherwise exist and which enhance the virulency of the microbe, and hence increase the toxicity of its ptomain. Indirectly, therefore, autointoxication must be considered a factor in bacterial action. In dealing with the general question of autointoxication it should be remembered that when proteids are placed under the action of gastric and pancreatic juice they are changed into a hemi- and an anti-group. The anti-group is, as J. A. Wesener points out, broken down into antialbumose and a small quantity of antipeptone. This latter is a stable body which does not yield to the digestive juices or even to diluted sulphuric and hydrochloric acids. It is absorbed by the small intestine, but does not replace any waste of the used-up proteid of the body. Antialbumose is changed to serum albumin and is the one that [illegible]ished th[illegible] with [illegible] food. The al[illegible] causes death; the blood fails to coagulate, by reason of the fact that the lime salts are precipitated by this body. If for any reason the epithelium of the intestine fails to perform its functions of changing this body into serum albumin, toxic symptoms will arise.

*Presented in a symposium on Interstitial Gingivitis, to the Section on Stomatology, at the Fifty-first Annual Meeting of the American Medical Association, held at Atlantic City, N. J., June 5-8, 1900.

[1] The International Dental Journal, February, 1900.

While uric acid is charged with being the chief factor in autointoxication, its importance has been overestimated. It is a thermometer of the extent of autointoxication rather than its chief factor. Recent investigations, as J. A. Wesener remarks, show that uric acid represents the metabolism of the nucleins of the body, and is in no way related to the albumins taken in as foods, for these last bodies of the group are very poisonous. The necrosis arises as follows: The leucocytes break down easily because the carbon dioxid remains too long in the tissue spaces; the nucleinic acid which is liberated in this way attacks the connective tissue, etc., irritates it, and this forms a good basis for destruction of nucleins.

A factor in autointoxication is non-performance of the process of elimination by the various excretory organs. In the urine alone, as Bouchard has shown, there are present each day, sufficient toxins in a normal individual to cause death if not excreted. This condition is notoriously increased after prolonged nervous explosions like those of epilepsy or hysteria. This was pointed out 30 years ago by Meynert, who showed that the status epilepticus or condition of repeated convulsions was due to accumulation of a proteid or nitrogenous body in the system. This status epilepticus is preceded by an increased amount. The same is true as to the influence of non-elimination from the excretory organs—the bowels, lungs and oral cavity—as well as the non-exercise of its poison-destroying powers by the liver. The non-elimination factor, moreover, interferes with ordinary digestive functions, and hence increases its own extent. The other factor in autointoxication is the production of toxic products in such quantity as to prevent their destruction by organs like the liver and consequent elimination, since a product to be properly eliminated must be reduced to a certain chemical type.

Autointoxication of the gastrointestinal tract takes place during any period in the life of the individual. Especially is this true in degenerates, in disease and in later pregnancy. In these states the eliminating organs do not perform their functions. The amount of bile excreted is an important factor in aiding digestion: 1, It is a solvent, a large amount being necessary; 2, it is an alkaline substance, producing alkalinity of food after it leaves the stomach, thus aiding the pancreatic and intestinal juices to neutralize the acidity of the chyme; 3, a purgative, its presence in the intestine stimulates the peristaltic action; 4, it is an antiseptic, thus preventing the growth of bacteria; 5, its alkalinity causes the emulsification of fats; 6, it assists absorption; Pavy's experiments have shown that moistening an animal membrane with bile accelerates osmosis; 7, when excreted in large quantities bile passes through the intestinal tract, coloring the feces.

The pancreatic juice is likewise an important factor in digestion. It is coagulated readily, being rich in albumin. Owing to its alkalinity, when brought in contact with chyme containing gastric juice, it neutralizes the latter's acidity. Kuhn, Chittenden and others have shown that pancreatin is made up of two or three ferments, each having an individual action: 1, It mixes with the bile, causing emulsification of fats; 2, trypsin, which is analogous to pepsin, acts in neutral or slightly acid solution; 3, amylopsin or diastase, which resembles ptyalin, is more powerful than the other two, and converts the remaining starch into maltose. This, however, is aided by the previous action of ptyalin converting the starch into dextrin. It will be seen, therefore, that secretions of the liver and pancreas prepare the food for absorption after it has left the stomach.

Stockton, Elsmer, Boas, Ewald and others have shown that indigestion may be due to the following: 1. Disorders of the senses of smell and taste; 2, insufficient mastication; 3, alteration of saliva in quantity or quality; 4, absence or excess of hydrochloric acid, absence of pepsin, insufficient muscular power; excess of lactic acid in the stomach; 5, alteration in the biliary or pancreatic secretions; 6, excessive motility or torpidity of intestinal muscles, together with abnormal fermentative processes; 7, torpidity of the liver; 8, general poisoning, toxic influences; 9, altered blood-supply, in amount or quality; 10, nervous irritation, causing some of the symptoms of any of the above conditions. The influence of emotional states in the secreting process, and thereby directly on autointoxication, is illustrated in the fact long ago pointed out by Tuke, that pleasurable emotions increase the amount of gastric juice secreted, the opposite effects being produced by depressing passions.

As Bichat showed decades ago, sudden emotion may produce marked effects on the secretion of bile, and occasion jaundice. Cases are far from infrequent where emotions like jealousy produce mimicry of gall-stone colic in neuropathic individuals. Murchison, Christison and Thompson have traced attacks of biliary colic to jealousy. I have a number of patients in whom grief, worry from family or business troubles and overwork have caused such mental depression as to interfere with the excretory functions of the eliminating organs, and thus produce indigestion autointoxication.

Other liver changes from sudden nervous disturbances, whether of a mental type or not, are not rare. As mental impressions are communicated to the central nervous system purely through mechanical changes in the nerves, such influence must be purely material in operation. As the brain exercises a checking influence on the operations of the liver it is obvious that these mental influences can produce two effects: 1, The mental shock might increase the checking action of the central nervous system on the local ganglia of the liver; 2, the mental shock might destroy the checking action on the liver ganglia, and in consequence these may work too fast and exhaust themselves. Either of these two conditions would interfere with a poison-destroyed action of the liver, and accumulation of waste products would be the result. What is true of the liver is true of the other organs.

No one condition will so change and affect the secretions of the body as to produce autointoxication to such an extent as extremes in temperature. These sudden changes have been most marked in Chicago in the past winter. A change in temperature from 20 to 45 degrees in twelve to twenty-four hours was not uncommon. The result is that trophic changes and metabolic action were most marked. It was with difficulty that the excretory organs, especially the liver, pancreas, skin and kidneys, could adjust themselves in many cases to the freaks of temperature, as the result of which autointoxication was very noticeable, especially in those persons over 30 years of age and those who were suffering from previous indisposition. Sick headache, dizziness, indigestion, a sense of fullness, itching of the skin, eruptions, inflammation of the mucous membrane of the mouth and gums, peeling of the fingers and odor in the axillæ and groins are quite common.

In healthy people a natural movement of the bowels every day may take place and yet decomposing food may be retained in the small intestine. It is not known that the bile prevents decomposition. If, as is frequently the case in degenerates, the liver and gall-bladder are not large enough, or, if in disease, a sufficient quantity of bile is not secreted, fermentation will take place. Again, one may eat more nitrogenous food than can be digested, or than can be taken care of by the bile, in which case decomposition will ensue. After one has obtained his growth this is not infrequently the condition. When fermentation and decomposition of the carbohydrates take place we have the various fatty acids produced. When the albuminous substances decompose, ammonia, sulphuretted hydrogen, indol and skatol, leucin and tyrosin are found. Aaron and others have demonstrated that ptomains and toxins are constantly found in the intestinal canal owing to bacterial action. In many people, fruits, cooked, as well as uncooked, will produce fermentation in the stomach and intestines, thus producing the most violent forms of autointoxication.

It is claimed that the symptoms of autointoxication are manifested, first, in the nervous system; next, in the circulatory; then in the tegumentary and, finally, in the kidneys. From my own studies, one of the first symptoms, I believe, is—especially in the young—sick headache. The relief which follows a thorough evacuation of the bowels is a familiar phenomenon. Some more marked psychic symptoms are depression of spirits, cranky notions, distaste for society and melancholia. In most cases of autointoxication or dyspepsia, as these cases are called, neurasthenia results. In the neurasthenic condition, the skin and mucous-membrane poisoning occurs. The most common of these is urticaria or hives, after eating lobsters and other shell-fish, or strawberries, or after the use of tobacco.

The mucous membrane throughout the alimentary canal, especially that of the mouth, is frequently involved. Changes in secretions, thickening of the mucous membrane, and, finally, inflammation of the gums and alveolar processes are noticed. I have called this interstitial gingivitis. So sensitive are the alveolar processes, gums and mucous membrane, owing to their transitory nature, that their inflammation and absorption might be considered one of the first, if not the first, symptom of autointoxication. Two predisposing factors assist greatly in influencing the disease: previous inflammation and age. When the gums have once become affected by drugs or other causes, indigestion, by producing autointoxication, will quickly set up irritation and inflammation.

People over 30 years of age, especially those of sedentary habits, do not require either an excessive nitrogenous or starchy diet. In such cases the food is not digested, and ptomain poisoning results. Autointoxication with gum and alveolar-process inflammation and absorption takes place.

[Discussion of the Symposium of which this paper is a part will appear after the last paper, next week.]

South African Hospitals.—Evidence taken on the opening day of the Commission on the South African Hospitals pointed out the efficient method in which the army medical service was conducted. A varied array of witnesses from medical, military, and civil life were unanimously in favor of the completeness of the medical arrangements. A full report is given in the *British Med. Journal* of August 4.

THE THERAPEUTIC USES OF THE THYMUS GLAND.*

SOLOMON SOLIS-COHEN, M.D.
PHILADELPHIA.

Mr. President and Gentlemen:—It is always a pleasure to meet my colleagues of the New York County Medical Association. I only regret that what I have to offer for your consideration is not very satisfactory. If at the close of my remarks you shall think that they have been vague and inconclusive, even contradictory, I shall have left on your minds a truthful picture of the state of our knowledge concerning the subject on which you have honored me by asking me to address you.

It has long been known that children are liable to sudden death, attributed in some mysterious way to enlargement of the thymus gland. Authors have written learnedly on the subject, explaining, or rather failing to explain, these cases. In his classic study on diseases of the thymus gland, your honored fellow-townsman, Dr. A. Jacobi,[1] points out how a slight increase in bulk of the tissues occupying the comparatively small space of the mediastinum may produce fatal compression of the trachea.[2] But why should the thymus suddenly enlarge to this fatal point? Some writers attribute the symptoms of thymic asthma to toxemia, whether from hyperthymization or hypothymization. But, again, why this sudden change in the secretory activity of the gland?

Whether these cases are really examples of disease of the thymus or of an unfortunate effort of nature to overcome some other disease, I, at least, do not know. The function of the gland will have to be better known before we can decide; and until we know both the physiology and pathology of the organ better than we now do, we shall lack a sure basis for thymic therapy.

Clinically, too, we are confronted with the contradictory reports of equally competent observers upon the therapeutic action of the thymus gland in various cases of disease. One reason for this is to be found in the very varying nature of the preparations administered. In the beginning the fresh glands of recently slaughtered animals were used. Later, commercial preparations, desiccated powders, tablets, glycerin extracts and solid extracts have been employed.

I wrote to the leading manufacturers of America and England in order to get some idea of the manner in which the preparations on the market are made. Messrs. Burroughs & Wellcome, to my surprise, excused themselves from replying to my query. Messrs. Parke, Davis and Company said they used only the glands from sheep, usually young ones, such as the butchers sell for lamb. Messrs. Armour and Company said that the glands were taken from calves, 3 to 4 weeks old, after these animals had passed the government inspection. Neither of these houses mixes the glands of different kinds of animals. They both courteously and fully described their process of selection and desiccation. The Phospho-Albumen Company replied that they used the thymus gland from young lambs (young sheep) only, and described the process by which they make an extract instead of a desiccated preparation. These three American preparations, as we see, differ from each other either as to the source or method of preparation. If we could have the active agent or agents, our therapy would be more scientific and our observations more definite.

The dose of thymus preparations at present, is

---

*Address to the New York County Medical Association, May 21, 1900.

"enough." Small doses are best, at first, given tentatively, to determine individual reaction and tolerance, but I have seen no bad result from very large doses. The raw or slightly cooked glands have been given in quantities of one-half ounce or more, in single or divided doses, daily or thrice weekly or less often. Of the commercial powders and tablets I have given from 5 to 90 grains daily. To get and keep good results the medicament should be given persistently for long periods.

Its application is not to accidents, such as infections, but to affections of metabolism; and chronic diseases must receive chronic treatment.

Thymus therapy is due, in a measure, to a butcher's happy ignorance.

Mr. David Owen,[3] of Manchester, England, administered, as he thought, large doses of thyroid gland to a patient with exophthalmic goiter, and recovery ensued. As a rule, thyroid feeding injures such patients, though I have myself observed and reported one of the exceptions to this rule on record. At the instance of Dr. Hector Mackenzie, who observed that the quantity of gland substance given by Mr. Owen would require several thyroids, further inquiries were made, and it was found that the butcher had been furnishing thymus—"neck sweetbread"—instead of thyroid gland.

Mr. Owen then deliberately began the use of the thymus gland from the calf. In one of his cases which did not improve, it was found that the thymus gland furnished was from the sheep, and on the substitution of calves' thymus glands, improvement began. The good effects noted were greater or less reduction of the thyroid tumor, great reduction of the tachycardia, and control of the nervous symptoms, together with improvement of the general nutrition.

Another British observer, Mr. Todd,[4] has published a noteworthy case, with sphygmographic tracings and pulse chart absolutely convincing. The case was one of severe exophthalmic goiter, in which rest and all of the approved drugs had been used, notwithstanding which the cardiac symptoms became steadily worse. This patient had finally recovered under the administration of fresh thymus gland from the calf. I call attention to this particular case as one which entirely meets the criticisms of Dr. Hector Mackenzie, of London, Dr. Kinnicutt,[6] of your city, Dr. Parker,[7] of London, and other good observers who have used thymus gland in exophthalmic goiter without noting special benefit; while Watson Williams'[8] patient was apparently made worse by the treatment.

Parker's patients, however, professed to feel much better from the medication, despite the lack of objective improvement. Furthermore, many competent and experienced physicians, in Europe and America—Mikulicz[9] Cunningham,[10] Edes,[11] McKie,[12] Maude,[13] Reinbach,[14] and others—have had favorable results that are not to be attributed either to suggestion or to the well-known tendency of Graves' disease to spontaneous improvement or recession. I have elsewhere published my own[15] good results with the use of thymus gland in the treatment of exophthalmic goiter. Its effect is especially marked upon the nervous symptoms, but Todd's case illustrates its power over the heart, and Mikulicz, Bruns[16] and others have shown its influence upon goiter, both in connection with and apart from Graves' disease. Upon the proptosis its effect is perhaps least.

Recently I suspended the use of thymus gland in this disease, not because it did not give good results, but because the adrenal substance promised even better ones. I have found, however, that some cases present symptoms that can be controlled by thymus gland and not by adrenal gland, while others present symptoms that can be controlled by adrenal but not by thymus. A combination of the two has thus seemed to me better than the use of either alone; but I have not yet had a sufficient number of cases treated in this way for a long enough time to warrant reporting them or drawing conclusions. At one time I thought that adrenal produced less effect upon the goiter, more upon the heart, than thymus; but in other cases the reverse has been noted. The puzzling pathology of exophthalmic goiter gives us no help in theorizing, and empirically this adds but one more to the contradictory observations.

Physiologists do not give us much help as yet as to the nature of the active principle of the thymus gland, or as to its function in the human body. Foster[17] says that from the gland a proteid-like globulin may be extracted, which seems to have some special relation to the formation of fibrin. When injected into the veins it gives rise to extensive vascular clotting. The thymus gland is rich in extractives—xanthin, hypoxanthin, leucin, lactic, succinic and other acids have been found in it. "Its chief function," he states, "seems to be associated with events taking place before birth, or in early life."

Beard[18] has recently revived the hypothesis of Kölliker that the thymus gland is concerned in the production of leucocytes. His argument is founded on observations made on the smooth skate—*Raia batis*—which seemed to show that the earliest production of leucocytes was in that sac developed from the primitive branchial arch, which later on becomes the thymus gland. These cells he believes to be the parents of all the glandular structures. Cases have been reported in which the enlargement of the thymus gland has been associated with leukemia or hyperleucocytosis. These are of many kinds. In some cases tumors, genuine sarcomata are found;[19] in other cases vague hyperplasias, perhaps associated with general lymphatic enlargements, as in the status lymphaticus. In acute leukemia[20] and Hodgkins' disease there have been found tumors of the thymus gland, some of which have been reported as sarcomata, but which later observation seems to have demonstrated to be collections of cells resembling in their nature and arrangement such a process as would be expected from a revival of the involuted thymus.

In exophthalmic goiter the thymus gland is frequently found to be enlarged at death.[21] Owen looks upon this as a compensatory revival. It is also found to be enlarged in acromegaly and in pulmonary hypertrophic osteoarthropathy; perhaps similarly in an effort of nature (reaction) to restore by supplement or antagonism a disturbed metabolic balance.

A number of cases of epilepsy[22] with mania have been reported in which the thymus gland has been found enlarged at death. These cases are supposed to indicate some toxic properties of the excessive thymus secretion, and are thus associated with thymic asthma. But the evidence is susceptible of other interpretation.

Removal of the thymus gland has been attempted by some observers, with contradictory results.

The thymus gland is found to be a necessary organ in the frog, but less so in dogs.

I quote from Norton's[23] excellent summary, verified by reference to his sources.

Tarrelli[24] extirpated the gland from dogs, with the following results:

1. No dog died of the operation.

2. Dogs showed a great voracity, but grew less than dogs in normal condition.

3. The blood showed a diminution of red-cells and hemoglobin, but an increase of leucocytes, which kept on increasing from one to one and a half months after operation; it showed also the presence of eosinophiles.

4. Dogs showed loss of strength four months after the operation.

5. Dogs' hair did not grow as well as in unoperated dogs; it lost its brilliancy, became very rough, and fell out easily.

The author draws no conclusions as to the action of the gland from these cases.

Abelous and Billard,[25] working together on frogs, give the following summary of their experiments:

1. The thymus in the frog is an indispensable organ for life.

2. Its total ablation is followed by severe troubles: *a*, dynamic—weakness, paresis, paralysis; *b*, trophic, discoloration of the skin, cutaneous ulcerations; *c*, alterations in the blood—hydremia, edema, hemorrhages, changes in the corpuscles.

3. Ablation of one thymus does not induce death.

4. We believe that frogs deprived of the thymus die of a true autointoxication, as is shown by the manifest toxicity of their secretions, when injected into frogs lately operated upon.

5. Subcutaneous insertion of the thymus does not prolong life materially, though it may restore the normal color of the skin.

6. Injection of a thymus extract from cattle into frogs causes an augmentation of the excito-reflex power of the spinal cord; at the same time the color of the skin becomes markedly darker, and if discoloration has commenced, the frog takes on its natural color. The effect of these injections seems then to present a true antagonism to the troubles which follow the extirpation of the thymus.

"It is Svehla,[26] however, who has up to the present time done the best experimental work with the thymus gland. He worked with a watery extract of human glands, as well as with glands from other animals. He states that intravenous injection of the thymal extract from man, cattle, dog, and pig, causes in dogs:

"1. A lowering of the blood-pressure, following weakness or paralysis of the vasoconstrictors.

"2. An acceleration of the pulse, due to a direct influence on the heart.

"3. In large doses it causes death of the animal, with appearance of restlessness, followed by collapse and dyspnea. Autopsies showed death in these cases to be due to suffocation."

Minkowski,[27] after feeding dogs with calf thymus or the nuclein obtained therefrom, noted a new substance in the urine, which he calls urotonic acid (imidopseudouric acid), and which he believes to be an oxidation product of the nuclein base special to the gland. It may be twenty-three times greater than the ordinary uric acid in quantity.

A. Clark,[28] of London, recently reported the case of an infant in which the thymus was found absent after death, and in which there had been extravasations of blood during life. This is interesting in connection with the known property of thymus extract to produce clotting when injected into the veins, and suggests some connection of thymic failure with hemophilia, and the use of the gland as a remedy in that affection.

A. E. Wright,[29] of Dublin, recommends for use a physiologic styptic prepared as follows:

Fresh and finely-minced thymus is extracted from twelve to twenty-four hours with ten to twenty times its weight of a solution containing 1 per cent. of carbolic acid and 1 per cent. of sodium chlorid; and to this is added, after straining, 0.5 per cent. of crystallized calcium chlorid. It is then made faintly alkaline, shaken and mixed with the effused blood, in the proportion of about 1 to 10.

Cunningham,[30] of New York City, in his experiments on dogs, found that the thymus extracts were as useful as thyroid extracts in combating or preventing the *cachexia strumipriva*, and as recent observations, especially those by Mendel,[37] seem to demonstrate that there is no iodin in thymus and that the iodin which Baumann[32] thought he had found in minute quantities in large amounts of thymus substance was, in fact, due to contamination by parathyroid substance, it is evident that the good results can not be attributed, as has been done by some, to iodin.

The same remark applies to Reinbach's[14] clinical observations. This observer relates the experience obtained in Mikulicz's clinic with the use of thymus extract in the treatment of ordinary goiters. Fifteen cases were so treated, while for comparison eight were treated with thyroid extract and two with thyreoiodin. It was demonstrated that thymus extract had a distinct influence in diminishing the size of the goiters in some cases, though nearly 50 per cent. were unaffected. Adenomata and cysts were uninfluenced both by thymus and thyroid extracts. No case recovered completely, and most of them required operation, but the remedy did no harm and gave rise to no unpleasant result. This, it is remarked, contrasts favorably with the thyroid treatment, since heart-failure is not uncommon after the exhibition of the latter. On the whole the effect of thymus treatment was thought to be greater than when thyroid extract was employed.

These experiments and experiences, showing a certain similarity between the action of thyroid and thymus substances, need to be harmonized with other observations showing dissimilarity or antagonism. Doubtless further research will show that the secretions of the ductless glands are complex; that there is a difference, physiologic and pharmacologic, between the gland-substance and the secretion; that both cell and cell-product change under diverse conditions; that, as with plants, for example, belladonna and pilocarpus, so with animal tissues, proximate principles largely antagonistic may exist side by side. This being done, we may then be able to find out just why certain substances in the two glands, or even the whole secretions, have under differing conditions opposing or supplementary functions. Cunningham, like Svehla, found that the thymus extracts dedepressed blood-pressure by a vasodilating influence; but according to my clinical experience, the blood-pressure is raised and vasodilation corrected by the administration of the thymus gland. Perhaps different conditions or the use of different active agents are here involved.

This much is certain, that in that group of cases to which I have called professional attention, under the name of vasomotor ataxia,[36] two distinct subclasses may be made; the one exhibiting greater tendency to undue relaxation of the vessels and finding its extreme type in Graves' disease; the other exhibiting a more marked tendency toward undue contraction of the vessels and finding its extreme type in Raynaud's disease. Between these two extremes exist all varieties, often with commingling of diverse tendencies toward vascular instability. Among the phenomena by which the two classes may usually be separated, the temperature-relation, that is, the reaction to heat or to cold, is prominent. Subjects of the one class complain of excessive heat sensations, undue sweating, and the like, even in comparatively mild summer weather, feeling, on the other hand, relatively comfortable in winter. Those of the other class suffer from moderate cold to a degree, and with symptoms, which, in the majority of men, it would require zero weather to produce, while summer is to most of them a time of comparative enjoyment; the exception being the infrequent cases in which a lack of perspiration even in summer is a source of distress. Administration of thymus or adrenal extract to those with undue dilatation of vessels—the summer patients—and of thyroid extract to those with undue constriction and want of perspiration—the winter patients—is often followed by relief of symptoms, Hence I am constrained to believe in a physiologic antagonism between the thyroid and the thymus—at least so far as vascular constriction and dilatation are concerned—in the patients and under the conditions mentioned. While I have observed some gratifying recoveries following the use of thymus substance, with and without the adrenal substance, in these cases, and in urticaria and asthma, and for the correction of the neurovascular disturbances of the menopause, I have also to record many failures; whether the cause of failure lies in the theory of therapy, in the diagnosis, or in further and undiscovered idiosyncrasies of the patient I know not.

Thus far we have dealt with what may be termed physiologic uses of thymus extract in therapeutics. As I have elsewhere pointed out, the therapeutic uses of animal tissues and secretions fall into three categories, which may be termed, respectively:

1. Homologous or direct physiologic organotherapy; in which actual or relative deficiencies in the functions of certain organs of the patient are remedied by the administration of functional substances derived from similar organs of the lower animals. This is best illustrated by the use of the digestive ferments in indigestion, and of the thyroid preparations in myxedema.

2. Physiologic organotherapy of the indirect type; in which the apparent function in the human body of a certain organic product leads to the administration of the like substance from animals for the production of a similar effect; and this, even when disease or deficiency of the given organ or secretion is not to be demonstrated or may not be suspected. The use of adrenal substance locally or internally to produce vasoconstriction is the most conspicuous example of this class.

3. Heterologous organotherapy; in which the pharmacologic properties of substances of animal origin are used for the production of effects having no reference to the physiologic uses or pathologic capabilities of the living gland in the human body. Just as strychnin or arsenic affects the animal metabolism and produces certain toxic or therapeutic results, so do substances of animal origin; and it may be that such uses will be found for all of the animal extracts.

Under this last head, perhaps, come the empiric uses of the thymus gland, to which I shall now direct your attention.

Folloing Mackenzie's[5] suggestion, that the good effect of thymus gland in certain cases of exophthalmic goiter was due purely to its influence upon nutrition, Kinnicutt,[6] and others, gave it to patients with pulmonary tuberculosis, noting during its use an increase in weight, with subsequent loss upon its withdrawal. It has been used with reported good results in rachitis and in marasmus. In one case of rheumatoid arthritis, associated with exophthalmic goiter, under my own care, the joint conditions improved, together with the general condition of the patient. I have since employed it in six cases of uncomplicated rheumatoid arthritis, with relief in one case, and with failure in the others. Macalister,[33] probably the first to use thymus gland deliberately as a therapeutic agent, found it remarkably useful in a case of pseudo-hypertrophic paralysis. Its use in chlorosis, by Bloudel,[34] may either be nutritive or may be brought into relation with the narrowing of the aorta found alike in chlorosis and in cases of the *status lymphaticus* with enlargement of the thymus gland.

Chittenden[35] has shown that the lymphoid cells of the thymus gland contain a much larger proportion of phosphorus—3.5 per cent.—than is to be found in the nucleoproteid of any organ except the pancreas—4.71 per cent. This richness in an easily assimilable element, which certainly is of profound importance in the structural and functional metabolism of the higher tissues, may explain the good effect of thymus therapy in diseases of nutrition. Its good effect in exophthalmic goiter I believe to be connected with its physiologic function, probably falling under the second rather than the first of our categories; but as to this, in common with nearly all other problems relating to the thymus gland, we still await further information from careful, scientific and skilful observations, in which I trust other New York physicians will do as good work as has been done by those of your colleagues whose names I have so frequently mentioned.

MEDICINE AND MEDICAL MEN IN THE UNITED STATES.*

A. JACOBI, M.D.
NEW YORK CITY.

It is the purpose of this address to contribute to your knowledge of transatlantic medicine and medical men. That is why I have to ask the pardon both of my countrymen and of all of you, but mainly of the French gentlemen here assembled, for using—or, perhaps, misusing—a language not my own, but better known to most of you than mine. In this way I hope to serve the ideal of the International Congress, which admits the delegates of medicine from all over the globe, recognize three languages as equivalent, listen to contributions on all possible topics connected with medicine and its numerous tributaries that are offered by the glory-crowned heads of the profession and by those on whose shoulders, now young, will rest the future of medical science and practice, and thus give an example of cosmopolitanism, the universal realization of which must be left to the coming century.

Many millions of the population of the United States are European immigrants or their offspring; commercial interests between the two hemispheres are numerous, and there is a daily intercourse through correspondence, telegrams and travelers; the French and German languages are much studied in America, but while European literature is copiously imported into our country, our own is not so well known in Europe. Even European governments send to us representatives to study economical, mechanical and agricultural questions. But it appears that there are difficulties as regards the international appreciation of what concerns American medicine and medical men. Possibly it is because the intercourse between medical men is not sufficiently extensive and long. When our best men come to Europe it is for the purpose of rest; you find, unfortunately, but few of the great—mostly older—men at the international congresses. That of Washington in 1887 was not much frequented by Europeans for reasons satisfactory to themselves. Our young physicians and students who flock to European universities are not and should not be taken as fair representatives of American medicine. Your own great or well-informed men rarely come to us to see with their own eyes. Books on general American topics, like that of the superficial and clumsy L. Buechner, of Germany, or that of the ignorant and shallow, though elegant Bourget, of France, written after a few weeks' limited observations with narrow opportunities, are more apt to obscure the mental view than enlighten the mind. The spirit of de Tocqueville is no longer alive in the tourist.

THE CLERGY AS MEDICAL ADVISERS.

The first advisers in cases of sickness, all over New England at least, were the clergymen. Indeed, the first news we have of diphtheria in that region came from them. John Rogers and John Fisk are known to have been preachers and doctors, John Foster, of Boston, wrote the first medical treatise published in America in 1677—"Rule to Guide the Common People of New England; How to Treat—Smallpocks or Measles, Etc." What might have been expected when real doctors took possession of the field occupied by the clergy, however, did not occur. For a long time the latter remained staunch friends of the medical practitioner. The Reverend Cotton Mather, in 1721, strongly favored the inoculation of smallpox and defended and protected Dr. Boylston, who was persecuted by the mob of Boston for having a mortality of 2 per cent. among those inoculated, compared with one of 14 per cent. among those suffering from genuine smallpox. It is different now, when there is no trade or profession more fond of sectarian medicine, and medical dilettantism than the clergy. Part of the latter, however, spent all its energy in another direful direction; the witchcraft prosecutions and *auto da fe's* were theirs, and mainly Cotton Mather's, while it is creditable to our medical forefathers that they had nothing to do with them.

EARLY AMERICAN PHYSICIANS.

The first physicians in the colonies came from abroad. Wooton, in 1607, Russell, in 1608, appear to have stayed but a short time, for it is reported that when John Smith was wounded, he had to go to England to be treated. The name of Lamontagne is mentioned in 1637, John Clark, of Boston, in 1638; Child, in 1644. There was but very little opportunity to learn in the seventeenth century. We know of no lectures except those of Dr. Giles Firman, who lectured in Harvard in 1647 on human osteology. At that time medical practice was learned in apprenticeship; young men would serve and study with a practitioner from three to seven years, the same time that Jacob slaved for Rachel, without getting her, after all. This system of apprenticeship was continued with more or less modification until recently. Indeed, most medical schools, until lately, would accept the apprenticeship with a preceptor in lieu of a year's college course. But in the early times those who had the means, and the ambition to learn, went abroad to Leyden, Paris, Padua, or Great Britain. They were mostly classical students; classical studies were, indeed, so much thought of that the Medical Society of New Jersey 120 years ago demanded Latin and some Greek as indispensable for the license to practice medicine. That was, unfortunately, changed; for until a short time ago the admission to a medical school depended solely on the sweet will of the untaught and ignorant ploughboy or drygoods clerk.

EARLY MEDICAL LECTURES AND MEDICAL SCHOOLS.

Our first information in regard to medical lectures refers to those on anatomy. Evidently that subject struck the imagination of chroniclers most forcibly. Dr. Thomas Cadwallader instructed students in Philadelphia between 1745 and 1751, as did Drs. John Bard and Peter Middleton, in 1750, in New York; Dr. William Hunter, in 1752, in Newport, R. I., and Dr. William Shippen, in Philadelphia, from 1762 until 1765, when the Medical College of Philadelphia was founded. He lectured on anatomy and midwifery, in agreement with the time which did not abhor, out of sheer ignorance, the incompatibility of anatomy and obstetrics. Historical justice compels me to add right here that it was a professor of anatomy, our famous poet, Dr. Oliver Wendell Holmes, in Harvard University, who, in 1843, long before the unhappy Semmelweis, proclaimed the contagiousness of puerperal fever, and the incompatibility of the lying-in room and the dissection-table. It was Shippen, the anatomist, who tried to establish a school of midwifery. Again, it is historical justice to proclaim that the injustice of man has not only interfered with the instruction, but in most states, even with the very existence of midwives, in contradistinction to the old Philadelphian. There were two medical schools before the War of Independence—one in Philadelphia, established in 1765, and one in New York, established in 1768. The first degree conferred in medicine was that of Bachelor of Medicine, in 1768; the first degrees of Doctor in Medicine were given in New York to S. Kissam and Robert Tucker, in 1770. Before 1776, when the war suspended them, these two institutions had conferred 51 degrees. The medical school of Harvard was founded in 1782; that of Dartmouth, N. H., 1797, and that of Lexington, Ky., in 1799. Thus, in 1800, there were five medical schools in what then was the United States. In New York the names of the professors were Richard Bailey, John R. B. Rogers, Wright Post, William Hammersley, Sam. L. Mitchell and David Hosack.[1]

---

* Read before the Thirteenth International Medical Congress, Paris, August 6, 1900.

The Medical School of King's College, in New York—the name formerly borne by Columbia—was discontinued, but in 1860 the College of Physicians and Surgeons, which was founded in 1807, simultaneously with the School of Medicine of the University of Maryland, took its place as a nominal, and a few years ago, as an actual, part of the Columbia University. Of the 156 medical schools which exist at the present time, three date from 1765 to 1800, twelve were established between 1801 and 1825, twenty-two between 1826 and 1850, thirty-three between 1857 and 1875, and eighty-six since. How many more have been so good as to disappear from the face of the American earth nobody cares to learn or to know; if we knew we should shed no tears.

In 1899 there were 156 medical schools in the United States, with 24,119 students; the latter have increased 142 per cent. in twenty-one years. Of the 156 schools, 21 call themselves homeopathic, with 1833 students; 7 eclectic, with 582, and 3 physio-medical, with 85 students. I hope nobody will ask me for an explanation of the three last terms, in this year, 1900; for I could not give one. Of the 156, 74 are departments of colleges and universities; 82 are separate institutions, and only 152 grant degrees. In addition to these 156 there are 10 medical schools for graduates, who come to the larger cities, mostly New York, for the purpose of taking courses, chiefly in specialties. In 1899 these 10 schools had 1916 students, of whom 73 were women.

Of the 10 graduate schools 3 are in Illinois, 1 in Louisiana, 4 in New York and 2 in Pennsylvania. Less than 2000 physicians are taught in these institutions annually, most of them in short courses. They employ 300 professors and 381 adjunct professors and instructors. There can be no doubt as to two effects; first, a good many practitioners of the country have a more or less brief opportunity to improve themselves, and, second, many practitioners of the large city bask in the sunshine of the professional dignity. Sometimes it seems as if plain-doctors were scarce at present. But there are some left.

At the time of the War of Independence there were probably 3500 physicians amongst the three million inhabitants of the colonies. It is estimated that 400 of these had received medical degrees. In 1798, 16 doctors of New York died of what was called "the plague;" there were 94 in New York in 1800.[2] At present we have probably 120,000 practitioners in the United States.

The ratio of physicians to population is less than 1 to 600 in our country, while in Great Britain it is 1 to 1100, and in Russia, 1 to 8500. Proportionately we have four times as many physicians as France, five times as many as Germany, six times as many as Italy, and six times as many medical schools as either of these countries. Medical teaching, however, will be better, more uniform and more in accordance with the real requirements of the people, when our 156 schools have been reduced to 25, and each of them is connected with a university as its medical department.[3]

Of the 55 political divisions in the United States, including Cuba, the Philippines and Puerto Rico, 21 report no medical schools. Of the 156 medical schools in 34 political divisions, 80 admit both men and women, 7 women only, and 74 are departments of universities or colleges. One requires a college degree for admission, namely, Johns Hopkins, in Baltimore; 12 a school course; 3 a three years'; 12 a two years'; 97 a one year's course; 29 a common school education, and 2 give no reports; 6 have a 9 to 10 months' course, 21 an 8 to 9, 45 a 7 to 8 and 84 less than 7 months' course; 141 maintain a 4 years' course, 10 a 3, 2 a 2 and 2 a 1 years' course. One is unknown.

MEDICAL PRACTICE LAWS.

The earliest law[4] relating exclusively to physicians was passed by Virginia in 1639, but, like the later act of 1736, it was designed mainly to regulate their fees. The act of 1736 made concessions to physicians who held university degrees. In only two of the thirteen colonies were well-considered laws enacted to define the qualifications of physicians. The General Assembly of New York, in 1760, decreed that no person should practice as physician or surgeon in the City of New York till examined in medicine and surgery and admitted by one of His Majesty's Council, the Judges of the Supreme Court, the King's Attorney-General and the Mayor of the City of New York. Such candidates as were approved received certificates conferring the right to practice throughout the whole province. A similar act was passed by the General Assembly of New Jersey in 1772.

In 1840 laws had been enacted by the legislatures of nearly all the states to protect citizens from the imposition of quacks. Between 1840 and 1850, however, most of these laws were repealed, or were not enforced, as a result of the cry that restrictions against unlicensed practitioners were designed only to create a monopoly.

QUACKS AND QUACKERY.

As every people, high or low, cultured or uncultured, has just as good doctors as it deserves, it appears that one-third of those who practice, mainly in Germany, where for thirty years the practice of medicine has, by act of government, been lowered from a profession to a trade, are barbers, weavers, shoemakers, shepherds, waiters, workingmen, tailors, carpenters, etc. With us in America the dilettanti are mostly clergymen, the quacks mostly women, trained nurses, spinsters without occupation, etc. Quackery has been raised to a sort of religious creed, and is practiced and preached with fanaticism, not so much amongst the poor and untaught as amongst the better-to-do classes, the semi-instructed and half-cultured, the well or overfed and mentally unbalanced men and women. It is wonderful to what extent the so-called better classes of society, professional people, journalists, lawyers and the clergy submit to the imposture of frauds or to their own imaginations, based on ignorance or half-knowledge. Nothing is more apt to prove that one-sided information is far from being general culture. That is why we have all sorts of "pathies"—osteopathy, vitapathy, electropathy, hydropathy, divine healers, magnetic healers, christian scientists, faith curists, mind curists, sun curists, Zion curers, etc. In most states, and in New York also, these shams are unchecked; in spite of the apparent strictness of the law, they exist simply because under its wording it is found impossible to determine the exact meaning of "practice of medicine." It is in the cases of these enemies of the human race that the well-directed efforts of legalized county societies of medical men, supported by good lawyers, have often proved ineffective.

---

[1] David Hosack graduated in Philadelphia in 1791 and afterward studied abroad. He brought home with him a cabinet of minerals and a herbarium. He helped found the Historical Society of New York in 1804 and maintained the Elgin Botanical Gardens, between Forty-seventh and Fifty-first streets and Fifth and Sixth avenues, which now form part of the valuable property of Columbia University.—Sidney H. Carney, Medical News, Feb. 17, 1900.

[2] Sidney H. Carney tells us that about that time the gold-headed cane was still pretty universal, but small clothes disappeared rapidly and pantaloons took their place. He also tells us something of their pay. In Bellevue Hospital the attendants on plague cases received twenty shillings daily; at that time the hospital was three miles out of town. A visit amongst the people cost one dollar, a visit and dose of medicine a dollar and twenty-five cents, pills twelve cents; for going a mile out of town one dollar extra was charged; to Brooklyn three, and to Staten Island ten dollars. Venesection cost from one to five dollars.

MEDICAL SCHOOLS.

Medical schools grow like toadstools. Charters were granted by legislatures indiscriminately. These schools were self-sustaining; they were created by a few doctors who, in any town, combined to foster their own interests or that of a few friends. After the Medical College of Philadelphia, when reorganized in the University of Pennsylvania in 1792, had dropped the requirements of Latin and some Greek, of physics, natural history and botany, no preparatory education was expected of a matriculant. In many schools that is so to this day. These schools rivaled each other in the cheapness of their fees, in the shortness of their terms and in the easiness of their examinations. There was no clinical instruction of any kind fifty years ago, almost none, even in large cities, forty years ago, when physiology, chemistry, pathology, surgery and obstetrics were recognized as legitimate subjects for instruction. The term of lectures was from four to five months, the length of study, two such courses, which were identical, the teacher repeating his instruction twice to the uncouth candidates of medicine. The result of the examination after two such courses was a diploma, and this diploma carried with it the license to practice. Whenever a progressive medical school was anxious to raise the standard of education, it had to fear the loss of students on whom depended its fees, that is, its existence; and so it happened that the University of Pennsylvania had to rescind its good intentions, when, twenty-five years ago, it dared to lengthen its course of studies.

The power to confer degrees differs in the various schools of the forty-five states composing the Union.

Low standards in many professional schools[5] are due to a failure to subject the degree-conferring power to strict state supervision. In New York and Pennsylvania the laws now prevent an abuse of the power to confer degrees. A similar bill, strongly advocated by educators, was defeated in Illinois through the efforts of politicians and others in favor of low standards. In Ohio and Nebraska the statutes require only the nominal endowment of $5000 for a degree-conferring institution. In other states and territories, as a rule, any body of men may form an educational corporation with power to confer degrees without any guaranty whatever that the privilege will not be abused. From all of which you infer that it is impossible to judge of the Union from a single state. It should never be forgotton by Europeans that it takes forty-five states to make the United States, that these states are of different ages, populations, races and cultures; that they have different needs and requirements; that the greatest refinement of the East, the wild naturalism of part of the far West, the abject animalism of part of the South, are covered by the same flag, and that the boundaries of most states include the most various degrees of culture, and of the contrary.

The omnipotence of every medical school which gave the license to practice with its degree of Doctor in Medicine led to the grave evil of furnishing the country with low-grade practitioners. It is true that mainly in the Eastern states a few colleges would gradually improve their methods of teaching and lengthen their curricula, but they were exceptions to the rule. On the contrary, some of the schools in New York opposed bitterly every attempt at progress. Progress is due, not to the schools themselves, but to the influence of the medical profession that forced the schools to submit to public opinion, which insisted upon improvement of medical instruction. As early as 1837, in Philadelphia, and 1839, in the Medical Society of the State of New York, it was resolved that teaching and licensing should be separated.

ORGANIZATION OF MEDICAL ASSOCIATIONS.

This movement resulted in a call for a convention of delegates from all medical schools and societies in the United States. This convention of 1846 led to the formation of the AMERICAN MEDICAL ASSOCIATION, and was the forerunner of many attempts at giving us better doctors and better schools.

The Association of American Medical Colleges that was founded in 1890, the American Institute of Homeopathy, in 1844; the National Confederation of Eclectic Medical Colleges, in 1871, and the Southern Medical College Association, in 1892, deserve credit for earnest efforts in that direction. The greatest difficulty is found, as I have said, in the different standards of the people of our vast territory. Indeed, every century, and every people, has exactly the doctors it deserves, just as it has the rulers it deserves. That is why it is so difficult to arrive at a uniform standard all over the United States, and to arrange a reciprocity between the states which would allow the physician of one state to settle in another.

Much has been accomplished in this respect by a special committee, which reported at the meeting of the Association of Medical Colleges, in June, 1899.

Based upon the replies of fifty-six of the better schools, the following rules were proposed:

1. After July 1, 1900, every matriculant is to have a diploma from a high school or to pass an examination in the branches required by a high school.

2. Before a student can be eligible for the degree of doctor of medicine, he must have attended in a well-equipped medical school four courses of lectures of at least six months each. These courses must embrace at least 3300 hours' actual work in the school including—besides didactic lectures and recitations—500 hours of laboratory work, 150 hours of practical work, one or more obstetric cases personally attended by each student and 750 hours of clinical teaching. At least 45 months must intervene between a student's matriculation and the date of his graduation. All of the work should be fairly apportioned throughout the four years. No school can be considered capable of giving the requisite instruction that can not command each year at least 3000 hospital or dispensary patients for presentation to its classes.

How difficult it is to reach such ends may become visible by the single fact, that it took us, the medical men of the State of New York, as assembled in the medical society of the state—not of the schools, many of which were opposed to us—twenty years' constant exertion, with many defeats, to enforce a minimum of preliminary knowledge before matriculation, and the passing of an independent state examination after the degree of doctor was obtained from a medical school, both for citizens and for foreigners, before the license to practice was awarded. How important that is you may best understand when you are told that during the few years of the existence of the new law, of 4808 physicians examined, 3722, or 77.5 per cent., were successful; of 916 dentists examined, 77.5 per cent., and of 67 veterinarians, 44.7 per cent. were successful in obtaining their licenses. Thus the people were saved from the rubbish of incompetent doctors that, in former years, would have swelled the dangers to the public weal.

[5] Professional Education, by James Russell Parsons, Jr.

MEDICAL INSTRUCTION AND INSTRUCTORS.

The course of instruction has undergone great changes. A few years ago the so-called "seven branches of medicine" were taught in didactic lectures, repeated annually, to unprepared young men. There was no laboratory, and but little clinical work. At present the curriculum of all good schools extends over four years, includes systematic and compulsory work in chemical, pathologic, histologic and bacteriologic laboratories, and furnishes clinical instruction, no longer exclusively to large classes with no means of independent examinations on the part of the student. Moreover, the studies are graded, progressive from year to year, and in many schools the students are examined from year to year. This plan is objected to by those who favor absolute freedom of teaching and learning, in accordance with the theory of European continental universities. But the study of medicine should no longer be an individual affair. A school represents, in teaching those who are to practice on the people, the people itself; it should hold itself responsible to the people, and should be prevented from letting loose numbers of unprepared men or women; it should, therefore, make the exact studies without which no practitioner can at present perform his missionary work, compulsory. With advancing years, and after a long experience as a citizen, a practitioner and a teacher, I never forgot the ideals and principles of my youth that centered in the demands of individual freedom, but I was ever of the opinion that the public good should precede personal rights and control individual action. That is why I deplore the waste of a year or more in the life of a student as so many lost opportunities, and as a dereliction of duty.

What is demanded of a medical department of a university is the furnishing of a supply of amply equipped medical men. This does not exclude, however, the other responsibility and privilege of a university, viz.: To furnish opportunities and means for independent research. I have forty years of professional life behind me, and can assure you that the best original workers of after years, in and out of laboratories, were those who most closely attended the prescribed laboratory exercises.

It should also be mentioned as a hopeful sign of the rapid development of American medicine, that more and more men, and also women, have gone into medicine with all the warmth of hearts enlightened by intellects, and not for the money that may be, but rarely is, in it: and that quite often well-to-do men are carried into and kept in the laboratories of medicine by the enthusiasm engendered by the fascination of scientific research. They invest their own in their pathologic, biologic, histologic or chemic labors, and, as good citizens of the Republic, are satisfied with the interest their investment will bear to the domain of science in the service of humanity. Medicine, like politics, will be the purer for the money put into it, instead of being taken out of it.

It is hardly forty years since any systematic policlinical instruction was given in the best of our schools. Now, together with obligatory laboratory work, clinical teaching bids fair to assume the leading part in our instruction. But we are far from having European facilities. For what governments do for you, we who have but very few endowed medical schools, have to rely on the efforts of the profession and the benevolence of those who appreciate the good that is done to mankind by medicine and the medical profession.

Until a few years ago all sorts of educational institutions were benefited by philanthropists to the exclusion of medicine. Some change has taken place in that. From 1894 to 1898 the most notable gifts and bequests amounted to $2,631,000 for medical schools, and $16,593,701 for hospitals. The new medical school of Cornell University, situated in New York, has been presented with $1,500,000 by a single benefactor. In the City of New York alone the names of Vanderbilt, Sloane, Carnegie, Ollendorfer, Wœrishoffer, Seth Low, Payne and Pierrepont Morgan are not the only ones that should be mentioned and never forgotten. This, however, is not all. Only two years ago an unknown benefactor presented Columbia University with a fund wherewith to establish a ward in Roosevelt Hospital for the bedside instruction in the diseases of children for the medical students.

Benevolence is even more special than this. Mrs. Caroline Brewer Croft left $100,000—which, however, is reduced by the English heirloom tax—to Harvard University, on the condition that the income thereof should be spent on researches on the etiology and cure of cancer; the same purpose for which the legislature of the State of New York has for some years past spent $10,000 annually, to be used by Roswell Park, of the University of Buffalo. Special hospitals are either endowed or benefited in a similar manner. The Cancer Hospital of New York was established, or strengthened, by money given by Mrs. Collum and Mrs. Astor many years ago. It has, however, changed its destination and name since.

In this way much good has been done, not always well directed, though well meant. It is peculiar to notice, however, to what extremes different elements in the same nation will go. The same medical profession which has to be grateful for spontaneous offerings made in the interest of a scientific education is compelled to fight annually before almost every state legislature, and before the Congress of the United States, the dangerous fanaticism displayed in the antivivisection movement by the old women of both sexes and all ages.

Who were the teachers? In by-gone times a few practitioners would combine to form a school; legislative approval could be had for the asking; they were our "professors." This position gave them prominence in the public and increased their private practice; that is why the salaries, if there were any connected with their places, were commensurate with their possibilities to make money outside. Now and then the anatomist got more because his office took more of his time. Thus it happened that medical teaching was considered subordinate to other occupations, even in good schools. There are but few men of those times who are remembered because they were teachers; my old friend Alonzo Clark, one of the most learned, intelligent and eloquent professors the College of Physicians and Surgeons ever had, was almost forgotten before he died, not twenty years ago, and Austin Flint is better remembered by his textbook than by his personal teaching. That has changed. Teaching has begun to be considered as an end in itself in medicine as it is in other disciplines, mainly since the introduction all over the world of the exact collateral branches of medicine, which each require all the time and all the attention of a teacher, and mainly since the foundation and gradual development of the medical faculty of Johns Hopkins University, in Baltimore.

The systematic study of pathological anatomy and other so-called exact branches of medicine, histology, bacteriology, etc., is comparatively young. After all, they are young all over the world. Fifty-two years ago, when in Germany, and wanting to learn something about pathological anatomy, I had to go to Göttingen to listen to Frerichs, the only man who taught it in Germany, with the exception of Virchow, in Würzburg, and Rokitansky, in Vienna. These studies began in America at a very opportune time. T. Mitchell Prudden and William H. Welch had each a small pathological laboratory in New York in connection with the medical schools to which they belonged more than twenty years ago, but the systematic study and teaching commenced with the first development of the ideal of a university. While formerly we had some good medical schools, that furnished good average doctors for the community, we then approached the era in which we arrived at the knowledge that a university was to be an institution which was not only to impart knowledge, but also to create knowledge by original research. This ideal was first realized by the Johns Hopkins University, at Baltimore, since William H. Welch was called to the chair of pathology. We then had the peculiar spectacle, characteristic for modern medicine, that the newly-established medical school, contrary to what was customary both in America and in Europe, consisted originally in laboratories of physiology and of pathology. From that time on, remarkable changes took place in the configuration of most of our medical schools. Pathological anatomy became of fundamental importance, full professorships of that branch were established in most great schools, and also dozens of laboratories both for teaching and for research. Besides, many of the hospitals were supplied with pathological and clinical laboratories which vie with those of Europe, assistantships and fellowships were increased, and the students were taught to appreciate the new opportunities given and demanded by modern medicine. As far as T. Mitchell Prudden, in New York, is concerned, the volumes of publications emanating from the beautiful laboratory of the College of Physicians and Surgeons prove his enthusiasm and successes; and never was there a more influential teacher than Welch, who in two brief decades succeeded in disseminating exact research all over the United States through his students and followers, who have been called, one by one, to Philadelphia, Chicago, Albany or Boston. Dozens of them combined to celebrate on May 4, 1900, the twenty-fifth anniversary of his graduation as doctor in medicine by a precious volume containing original contributions of the very highest order, an honor to the famous master and an ornament of medical literature. There are in our recent American literature two more dedicatory volumes of similar import, one containing anatomical papers contributed by his pupils in honor of Professor Wilder, of Cornell University, 1893; the other, mostly clinical, written both by pupils and by American and European colleagues in favor of a New York teacher. In the face of such results, and such enthusiasm, and such love of work, who is there that still looks down on American medicine and American medical men?

AMERICAN MEDICAL LITERATURE.

According to E. H. Bradford,[6] while the best physicians of the colonies and the young states acquired their knowledge in Great Britain, their books were English. No books grow on the stumps of the forest primeval. When the War of Independence began in 1774, there was one book, three reprints and twenty pamphlets by American medical men. To-day there are 7000 American books and a countless number of pamphlets; there appear annually 300 books and pamphlets and 5000 journal articles. In one year, 1879-1880, the United States published 10,334, and Great Britain, 7476, books and articles. In the catalogue of Harvard University of 1875-1876, 44 foreign and 13 American medical books were recommended to the students; amongst the latter there was none on medical chemistry, obstetrics and surgery; in the catalogue for 1898-1899 there are recommended 71 foreign and American books.

The first regular publication of a journal occurred in 1790. It carries the following title: *A Journal of the Practice of Medicine and Surgery and Pharmacy in the Military Hospitals of France,* and contains absolutely nothing but translations. For another half century France was, together with Great Britain, almost the exclusive fountain from which the thirst of American medical men was quenched. The first original journal was the *Medical Repository,* whch existed from 1797 to 1824. Not long afterward the first quarterly, then monthly, *American Journal of the Medical Sciences* was founded by Dr. Isaac Hays. These seventy years it has preserved its reputation for its scientific spirit, industry and conscientiousness. Much that was new, much that is new, may be found in its volumes.

Of the large number of quarterlies, or monthlies, I may be permitted to mention the *University Medical Monthly,* of Philadelphia; the *Albany Medical Journal,* of Albany; the *Postgraduate,* of New York, and the *Therapeutic Gazette,* of Philadelphia, not to speak of special journals, such as the *Annals of Surgery,* the *Archives of Pediatrics,* the *American Journal of Obstetrics and Diseases of Women and Children,* the *Archives of Ophthalmology and Otology,* the *Journal of Cutaneous and Genito-Urinary Diseases,* the *Journal of Mental and Nervous Diseases,* and many others, some of which are now and then quoted in Europe, and all of which deserve more attention than they have hitherto commanded.

There are in every nation some publications which in their individual spheres demonstrate the very best that can be accomplished, and by which the intellect and industry of a people should be measured. Such proofs of the achievements in medicine in America are contained in the *American Journal of Experimental Medicine,* edited by Welch, and the *American Journal of Physiology,* by Bowditch and others. They are the pride of those of us that have lived through the most important period of the development of American medicine, and equal any of the European productions of similar claims. I know they have met with the unstinted praise and applause of **European** masters.

As an [illegible] to so [illegible] can not [illegible] is of [illegible]

6. Bc [illegible]

which appear all over the United States. Many are printed with honest intentions, others for the purpose of advertising their editors or of puffing proprietary articles. The growing commercialism of the end of the century grasps every opportunity, and medical, like every other branch of literature, is prostituted in the interest of social, professional or financial egotism. That is why the 300 medical, or alleged, medical, journals of the United States could well be reduced to fifty. If this were done, both medical knowledge and ethics, and the independence of medical journalism would be served to better advantage. Under the present circumstances the medical publications live more on advertisements than on subscribers, and both the publisher and the editor soothe their ethical and scientific conscience, if it ever existed, with the glitter of gold. I have been told mainly in the medical magazines both of France and of Germany, that the same occurs in your countries. I speak, however, of what I know, and I am best informed of what is going on in mine.

Among the most important instructors of the medical profession in our country are the great weekly journals which appear mostly in the large cities: New York, Philadelphia, Boston and Chicago. Most of them have a large number of subscribers, and have existed long. *The Boston Medical and Surgical Journal* has reached its 142d, the *New York Medical Journal* its 71st, the *Medical News* its 76th, and the *New York Medical Record* its 57th volume. The Journal of the American Medical Association, which has appeared for eighteen years, takes the same place in relation to the American Medical Association that is occupied by the *British Medical Journal* in relation to the British Medical Association. It was founded to publish the proceedings of the association, which from 1848 till 1882 had published thirty-three volumes, and, by opening its many pages to contributions from other sources, has improved both in material and tone from year to year.

I must not close these remarks on the weekly journals of my country without mentioning the *Philadelphia Medical Journal,* which was founded by a society of medical men that wished it to be independent of the medical publishers both in its finances and in its scientific and ethical management. We in America are peculiarly situated; if you in other countries are no better off, it is your fault, as it is ours. There are very few journals in America that pay anything to the contributor, and when you want reprints you have to pay for them. The policy of a journal, the selection of the advertisements, sometimes even the admission of articles more or less scientific or quackish, is to a greater or lesser extent in the hands of the publisher. It takes an editor of unusual character and prudence either to hold his place or to be removed unceremoniously. But the publisher gets rich; that is what, in his opinion, medical science, art and quackery are made for. This condition of things was to be changed by the newly-established *Philadelphia Medical Journal.* It has succeeded to a certain extent. It furnishes a large weekly edition, with good, original articles, and well-selected and digested extracts of whatever is best in the medical literature of both hemispheres, with a more ethical class of advertisements than most other journals can boast of, with a fearless editor, and with a list of subscribers that has exceeded 10,000 within two years.

Contributions to the literature of medicine, not of equal rank, are furnished by the large societies, particularly of the states. Many of them publish annual reports. The American Medical Association published thirty-three volumes before its transactions were collected in its journal. The New York Academy of Medicine has furnished nineteen volumes since 1847, which are found in many libraries of Europe; the College of Physicians of Philadelphia, twenty-nine since 1787. The very best, certainly among the best, are the productions of fourteen special national associations, which were founded at a period in the life of the American Medical Association, when its results did not satisfy the expectations of those who had no time to spare for entertainments, excursions, medico-political wrangling and other pastimes. These men, most of them of a specialistic turn of mind, and bent upon filling their time with work, congregated into special associations, whose members were recruited from the vast territory of the United States. The oldest of these seceding associations is the "Ophthalmological," which was founded in 1864. The majority have a limited membership. The Association of American Physicians had originally 100, now 125; the Pediatric, 40, now 60 members. The object was to select the working members of the profession only. Thus it has happened that their contributions to literature are very valuable indeed.

The Ophthalmological Association has published until the beginning of this year 8 volumes since 1864; the "Otological," 6 since 1868; the "Neurological," 22 since 1875; the "Gynecological," 23 since 1879; the "Surgical," 16 since 1881; the "Climatological," 14 since 1884; the Association of American Physicians, 13 since 1886; the "Orthopedic," 11 since 1889; the "Pediatric," 10 since 1889, and the "Anatomical," 8 since 1888. The Genito-Urinary Association publishes its transactions in the *Journal of Cutaneous and Genito-Urinary Diseases,* and the "Physiological" in the *American Journal of Physiology.*

In addition to those there are five volumes of unusual excellence, containing the proceedings of the "American Congress of Physicians and Surgeons," whose history is creditable to Mastin, Pepper, Weir Mitchell and others, who founded it. It is as follows: When all of those fourteen special national associations had existed for a greater or less time, and when among the most comprehensive and philosophical minds of the nation the fear of unchecked specialism became more terrifying, it was resolved, amongst universal applause, that the "disjecta membra" should unite once every three years into a congress, whose meetings should be held in Washington, while the selection of the time and place of the two intervening annual meetings of the individual societies was left to their own discretion. In this way the union and unity of medicine was recognized and re-established—a very necessary step in our times, where the appreciation of the principles and purposes of humanitarian and scientific medicine are in danger of being lost sight of in the same degree that the horizons of the specialistic workers, in clinics, shops and laboratories become narrow.

Books are numerous, and of about the same nature as in Europe. Text-books for students on all possible subjects, and written by masters, or those who believe they are, some of them masterpieces, some indifferent, some catechisms, which, with their questions and answers, appear to be compounded by idiots for the use of idiots—"*que c'est un plaisir de se voir imprimé,*" says Molière—they all appear to find a market. It is perhaps invidious to select, but I may here say in a general way, that some of our text-books in medicine, obstetrics, materia medica, diagnosis, embryology and many other branches compare favorably with yours.

Of monographs we have not so many as you; probably for the reason that the number and the variety of our many weekly and monthly journals devour whatever monographic essays have been prepared. Cyclopedias we have like you. It is very fortunate that the publishers, who, as a rule, were the first to give the idea, had no power over their contents. Those edited by Pepper, Keating, Loomis and Thompson, Mann and Stedman deserve as high praise as those published in Europe. A pleasant feature in medical bookmaking is the occasional participation of the Congress of the United States. Indeed, almost every state of the Union publishes frequently, at the expense of the people, papers and books of common interest, mostly geological, geographical and agricultural. Medicine owes to the appropriations of the national Congress, not always given with equal liberality, six volumes of the Medical and Surgical History of the War, two Medical Statistics, seventeen of the Index Catalogue of the Surgeon-General's Library, with its continuations, and the Library itself. The *Index Medicus* was not a government publication; at first printed by an ambitious and enthusiastic publisher, it was afterward secured by a small number of the subscribers willing to pay a big price. Its final collapse after twentv vears' strenuous labor on the part of Drs. Billings and Fletcher is not a creditable leaf in the book history of the profession of the United States.

There is, I believe, no country with a greater consumption of journals and books than the United States. There is probably no village doctor anywhere who has not a library, who does not buy books or cyclopedias from time to time, and take one or more journals. What Colonel Stoffel called thirty years ago the "instinct of labor" in the German Government Employer, is applicable in some other way, to the American medical student and practitioner. They waste no time, are industrious workers and voracious readers.

There is probably, however, no country with a book trade in a more wretched condition. In our city of three million inhabitants there is a single book-store in which a fair number of medical books in our own language of different authors and publishers are for inspection and sale. The latter sell their own books on subscription, by the aid of circulars and advertisements, and by agents, who vie with those of wholesale drug manufacturers in making doctors' lives miserable—it is individualism run mad. I see no better remedy than a syndicate of medical men for the purpose of publication and promiscuous sale.

Medical libraries were founded at an early date. The oldest—founded in 1762—is that of the Pennsylvania Hospital, in Philadelphia. The library of the New York Hospital was founded in 1776 and transferred to the New York Academy of Medicine two years ago; it then had 23,000 numbers. That of the College of Physicians, in Philadelphia, established in 1788, has about 56,000 numbers; that of Boston about 30,000. The largest medical library of our, perhaps of any, country, is that at Washington, in charge of the Surgeon-General of the Army; it contains more than 100,000 numbers, well selected, in excellent order and accessible to the medical men of the vast country, who, I know, avail themselves eagerly of the proffered opportunities. It was founded by William A. Hammond during our Civil War, continued and extended by John S. Billings, and is at present in charge of Dr. Huntington. Next in order is that of the New York Academy of Medicine, with about 60,000—or, with duplicates included, 80,000—numbers. It increases rapidly, partly through purchases out of the income of its library fund of $56,000, partly through donations, and partly through the accumulation of 700 medical journals on the shelves of its reading-rooms. Our brethren of the Kings County Medical Society, in Brooklyn, have just finished a new building, in which their rising library has been stored. Smaller medical libraries have been established in at least thirty cities, as far as I know. Large libraries are also in possession of private physicians. A year ago Dr. N. Senn, of Chicago, presented his collection of more than 24,000 books to the Newberry Library, of that city. I am acquainted with one in the possession of a New York physician of about 15,000 numbers.

ETHICS.

The ethical conscience of the physicians of the United States is exhibited in a great many ways. It is considered unethical for a doctor to own a drug store or a part of it; to take a patent on any invention of his own; to recommend over his name a patented instrument, a proprietary food or medicine or mineral water. This is illustrated by what happened to the famous Morton after his successful demonstration of the anesthetic effect of ether in the Massachusetts Hospital. After having extracted a tooth on September 30, 1846, without giving the patient any pain, he applied immediately for patent rights and sold individual office rights. Moreover, he kept his composition, which he called "letheon," a secret. It was then that the profession turned against him and forced him to admit that his "letheon" was sulphuric ether disguised by some aromatic oil. A medical man in America is prohibited ever to advertise his name, or office hours, or his specialty in a newspaper or lay magazine; even to announce his specialty, if any he have, on his cards. If ever his name, his departure from the country or his return is publicly announced, the suspicion is that he instigated the publication. If cases or operations of the same physician appear repeafedly in the public press, it is taken for granted that it did not occur without his knowledge, consent or prompting. All of these things impair a medical man's professional standing; they render him an improper candidate if he applies for membership in a medical society, or make him, if he be a member, the subject of discipline. In regard to all this, part of which may appear too rigorous in the eyes of Europeans, I beg to submit that, as in all democracies, laws and rules are not enjoined by a controlling government, so in their societies and organizations democratic medical men make their own rules and regulations, and see to it that they are obeyed. It is true that it takes democratic men, and gentlemen, to frame such strict rules, and to heed them.

Many of the rules accepted by American medical gentlemen are contained in a book compiled by an Englishman, Percival, in 1807. It was received as the code of ethics of the American Medical Association in 1847 and is still obeyed by those who know the book, or who do not know it, or even by those who never knew of its existence. One of the regulations of the code forbids consultations with homeopaths.

(To be continued.)

Dogs of War.—Scotch collies are trained for ambulance and bearer work in the German army. Their saddle bears a red cross, a flask and first-aid dressings. It is claimed that these red-cross canines will scent wounded men who under ordinary circumstances might be overlooked by litter-bearers and left on the battlefield to die.

EXPERIMENTATION ON THE CORD AFTER DECAPITATION.

Opportunity for investigation along this line is scarce. In the experiments made during operations on the skull or spinal column, the results are necessarily clouded by the action of the anesthetic, and still more by the tumor, or compression of the organ for which the operation has been undertaken. In healthy normal conditions experimentation can be made only during the few moments which immediately succeed the severing of the head from the body. Permission for such investigation is almost always withheld by the authorities, and public clamor would certainly be directed against investigation. In spite of this, however, Prof. A. Hoche[1] describes two such experiments made by himself upon decapitated criminals—in the one case three minutes, and in the other two minutes, following decapitation.

The effect of stimuli applied to the fast-cooling body becomes rapidly less as the hemorrhage robs the parts of their blood. The brain loses its power of responding to stimuli almost instantaneously, while the muscles and nerves still react to the electric current. The spinal cord is not influenced quite so rapidly as the brain by the loss of blood, and, therefore, if experiments are made during the first few minutes, results may be obtained. The experiments are undertaken chiefly with a view to determine the physiologic question, whether the substance of the cord itself reacts to stimuli. The question has so often been answered in the negative, because the bodies were experimented upon as long as one-half hour after death, when the anemia and temperature had rendered the cord insensible to stimuli. The investigator also endeavored to ascertain the portion of the cord first affected by the stimulus, whether in the motor columns, the motor nerve-roots, or the centripetal fibers. Hoche performed his work at the site of the decapitation, not desiring to wait, as previously had been done, for the body to be carried to some convenient laboratory.

The electrodes employed in the first case were two metallic points, each 1 mm. in diameter. These were placed, without any pressure, upon the freshly exposed surface of the cord, and a fairly strong induced current was passed. The corpse immediately became animated, the arms were flexed, the hands clenched, the legs stretched out in tonic spasms, while the chest-muscles expanded the thorax as in inspiration. It mattered not at what part of the cut surface of the cord the electrodes were placed. The results were always the same during the first few moments and were always symmetrical. Twelve minutes after decapitation, the result of the same stimulation was entirely different. All the muscles remained perfectly motionless, with the exception of the neck-group, which also became gradually weaker and weaker. The peripheral nerves directly under the skin responded for seventy-five minutes to the current.

In the second case, the work was undertaken two minutes after the head was severed from the body. The electrodes were placed on a common handle about 1 mm. apart. The current was so weak that only the slightest effect could be felt. The electrodes were now placed on the left lateral column of the cord and were sunk into the substance about .5 mm. Contractions in both arms, somewhat stronger on the right side, immediately took place; and faint reactions in the intercostals and abdominal group were also seen. The legs remained motionless. It must be remembered that the stimulation was at the level of the fourth or fifth cervical vertebra. The result remained the same, whether the electrodes were placed on the right or left side, anteriorly or posteriorly, in the white columns or in the gray matter. Nine minutes after the death the reaction slowly lessened, and at sixteen minutes it was entirely gone. The peripheral nerves, however, remained active to the current for a much longer time.

If we compare the results obtained in these two cases we see certain resemblances between them—the most noticeable being the rapid and successive decrease in the sensitiveness of the nervous elements. The substance of the spinal cord remains sensitive to stimuli for twelve to sixteen minutes, the nerve-roots somewhat longer, while the peripheral nerves respond for a considerable time longer than either. These facts accord with the theory of Hitzig, that, beginning with the cerebrum, the sensitiveness of the component parts of the nervous system diminishes toward the periphery—that of the brain ceasing in the moment of death, and that of the peripheral nerves from one to two hours thereafter. Pathologically, those parts retained their activity longest which had their various filaments most thoroughly insulated. Furthermore, both cases agreed, inasmuch as no desired group of muscles could be influenced by choosing a special site of the divided cord for stimulation. It may also be easily deduced that the cause of the various muscular contractions was not due to direct stimulation of the motor pyramidal tracts, for, if that were the case, the leg-muscles would have moved in the second case as well as in the first. Therefore, it must be that the motor tracts lose their power to respond to direct stimulation immediately after death. The only supposition remaining which is at all tenable is that we have to do with a result which is chiefly reflex in character; the greater the current the larger the area over which the contractions occur. Exactly how the effect is produced, however, must be the aim of further experimentation in this field.

SYPHILITIC AORTITIS AND ANEURYSM.

The relations of syphilis to the origin of aneurysms have not been definitely determined. The question is most complex. The pathogenesis of arteriosclerosis in general has to be considered, and our understanding of this subject is as yet principally based on theoretic considerations. We would naturally look to anatomic and histologic investigation for proof positive of the etiologic connection between aneurysm and syphilitic aortic lesions. But in the majority of cases arteriosclerosis and arteriosclerotic aneurysms in the syphilitic do not differ macroscopically and microscopically from the same processes in the non-syphilitic. Perhaps certain instances brought forward by Heller, who champions the existence of a pure, syphilitic aortitis that may give rise to aneurysms, constitute an exception to this statement. At the last meeting of the German Pathological Society in Munich, Heller again emphasized the importance of syphilitic aortitis in the etiology of aneurysms.[1] His strongest support is a case, examined in 1884 and described by Döhle,[2] of a pronounced syphilitic, 25 years of age, in whose aorta there were peculiar, circumscribed depressions—beginning aneurysms—in which the aortic wall was greatly thinned and wrinkled. The changes of ordinary arteriosclerosis were absent. There were foci of round cells about the vasa vasorum of these areas, with destruction of the elastic and muscular elements of the media, which in some places was replaced by scar tissue. These changes he regards as the result of a primary syphilitic aortitis. In other and similar cases he claims to have found miliary gummas with giant cells. When the changes are far advanced the aorta may also be greatly thickened, uneven, wrinkled from scars. Malmsten[3] and others have described similar lesions —"sclero-gummous aortitis"—and claimed that they may lead to aneurysms.

At the same meeting Straub[4] reviews his observations on the changes in the aorta in general paralysis. In 82 per cent. of eighty-four cases of general paralysis the aorta presented the changes claimed by Heller and others to be the result of syphilitic aortitis: a chronic proliferative aortitis, limited to the thoracic and the upper part of the abdominal aorta, characterized by a wrinkled, nodular thickening of the intima, radiating cicatricial depressions, and a tendency to obliteration of the openings of the branches; and microscopically by perivascular round-cell infiltration of the media, in some cases with numerous giant cells and gummatous formations. In a few of the cases were aneurysms with peculiar, sharply punched-out orifices. Of seventy-one non-paralytics examined during the same period changes in the aorta like these were observed but seven times, the seven instances all occurring, however, in syphilitics. As corroborative of the syphilitic character of this aortitis Straub cites, among other facts, the almost constant presence in the cerebral arteries of the changes first described by Heubner as syphilitic.

In the discussion Ponfick, Ziegler and Orth are incined to doubt the constant syphilitic nature of the aortitis described by Heller and by Straub because they had met with lesions of similar appearance in persons presumably free from syphilis. Ponfick, however, regards the changes in question as different from those of ordinary arteriosclerosis; he favors alcoholism as the cause, but brings no evidence in favor of this view. Chiari is somewhat skeptical as to the mesarteritis being the primary. Baumgarten has not seen the so-called gummous aortitis, and emphasizes the fact that the anatomic picture of syphilitic arteritis may be produced by other factors than syphilis. Hansemann, Beneke, and Babes believe that aneurysms may develop on the basis of syphilitic lesions, Beneke attributing a certain, ill-defined cellular weakness to the action of the syphilitic virus in consequence of which an artery so affected, e. g., the aorta, yields at the point of greatest mechanical pressure. Ziegler and also Babes believe that ordinary microbes, such as streptococci and staphylococci, may produce aortic lesions like those attributed to syphilis.

Taking it all in all, there is a great deal in favor of the existence of a peculiar syphilitic aortitis and consecutive aneurysmal formation, although much of the evidence is somewhat circumstantial in its nature. Perhaps we are not far away from the truth in regard to the rôle of syphilis in the production of certain aneurysms if we say "guilty but not proven."

THE UTILITY OF ALCOHOL AS A DISINFECTANT.

It has been much a matter of discussion whether alcohol is a bactericidal agent. and if it be, in what way it exerts its activity. When alcohol was first proposed for disinfection of the hands it was thought to be effective by acting as a solvent of fat, and thus preparing the way for the necessary intimate contact between the antiseptic solution and the epidermis. Later, bactericidal activity was ascribed to alcohol, and this was thought to depend principally on its dehydrating property. There are some observers, however, who believe that alcohol possesses doubtful, if any, antiseptic qualities. For the purpose of reaching an independent conclusion on this subject, Salzwedel and Eisner[1] undertook an experimental investigation, as a result of which it was found that a number of alcoholic solutions examined exhibited varying degrees of disinfectant activity, as compared with other well-known antiseptics, such as mercuric chlorid. carbolic acid, lysol, sapokresol. Silk threads, with dried bacteria, were employed as test-objects. the conditions encountered in actual practice being dup [illegible] ible.

[1] Berlin.

It was shown that alcohol is with most certainty destructive to staphylococci contained in pus dried on threads, when employed in aqueous solution with a specific gravity of .902 at a temperature of 19 C., that is, about 55 per cent. (by weight) spirit. The disinfectant activity of this solution was not quite equal to that of one to one thousand mercuric-chlorid solution, but, on the other hand, it was not less efficient than 3 per cent. solution of carbolic acid. Lysol and sapokresol in 1 per cent. solution, as well as lysoform up to 4 per cent. solution, were always less active than mercuric chlorid, alcohol, and carbolic acid. It was found that alkalinized spirit is more effective than ordinary alcohol in its action on dry threads, while the addition of mercuric chlorid or carbolic acid had no distinct effect in increasing the disinfectant activity. A generous coating of fat on the threads seemed to favor, while a thin layer rather retarded, the action of the disinfectant. The application of gentle heat—30 C. or below—was thought to facilitate the disinfectant power. The time required for the manifestation of this effect varied with the period of desiccation to which the threads were exposed, the bacteria in fresh pus, for instance, being destroyed by mercuric chlorid, alcohol and carbolic acid in five or six, or even in three, minutes, while if the threads were exposed after an interval of weeks or months, disinfection was, as a rule, not accomplished in less than from eighteen to twenty-four minutes. The results were equally bad when the threads were prepared from pus that had itself stood for a long time. These effects are attributed to inspissation of the medium containing the bacteria, retarding access of the disinfecting agents. Similar results were obtained with bouillon preparations made in the same way. Bacteria dried upon threads and placed for a long time in pure alcohol, and in some instances kept besides in the thermostat or the autoclave, retained their power of multiplication; but bacteria in a moist state, on the other hand, were destroyed in a short time by absolute, cold alcohol. This difference in effect is attributed to the desiccating and coagulating action of alcohol.

It appeared that the spirit capable of penetrating the bacteria with destructive effect should contain from 50 to 55 per cent. of alcohol by weight, although weaker solutions are not without a deleterious influence on the bacteria. The development of staphylococci was inhibited by the addition of 70 per cent. of alcohol by volume to the nutritive medium, the phenomenon being analogous to the process of alcoholic fermentation, where the yeast is destroyed when the percentage of alcohol reaches a definite figure. It was found that the addition of an acid, such as boric, acetic, or hydrochloric, to the alcoholic solution augmented its disinfectant activity, but it was then discovered that the reaction of the threads was neutral or alkaline.

From the experiments outlined it is concluded that in addition to its desiccating action, alcohol exerts an especial toxic influence on bacteria. Although this toxic effect is much less than that of mercuric chlorid and carbolic acid, properly applied, it is, with regard to its disinfectant power, comparable with the latter two, occupying an intermediate position between them.

THE TREATMENT OF TYPHOID FEVER.

From the time, in the early part of the present century, when typhoid fever was first discriminated from a number of other diseases presenting in common with it typhoid symptoms, constant additions have been made to our knowledge of this, one of the best-studied of the infectious diseases. Not much, it is true, has been added to the original description of the anatomic lesions or of the clinical features, but, among other things, it has been made clear that the disease can not arise spontaneously, always requiring for its development the presence of the typhoid bacillus; that it may be unattended with pyrexia, and also with intestinal lesions; and, lastly, we have had developed the serum-reaction, by means of which the diagnosis can be confirmed with almost absolute certainty in the vast majority of cases. It is, therefore, perhaps not unreasonable to hope that we shall eventually come into possession of a specific therapeutic remedy. Recognition of the fact that the disease is largely spread through the agency of water contaminated by typhoid bacilli has also provided the physician with a powerful prophylactic weapon, with whose aid the morbidity has been greatly diminished, while the practice of systematic cold bathing has done much to lower the mortality.

In a discussion of the treatment, Rump,[1] in a recent communication on the subject of typhoid fever, after referring to the absence of any specific remedy, points out that not much is to be expected from intestinal antiseptics. Copious evacuation of the intestinal tract at the beginning of the disease by means of calomel may be secured. In the general management everything should be done that will contribute to a favorable course of the disease, and all injurious influences should be avoided. An airy, well-ventilated room should be provided, with suitable bed-covering, careful cleansing of the skin and the accessible mucous membrane, food appropriate to the state of the intestine, adequate administration of fluid, control of injurious temperature, and careful treatment of complications. Great proteid destruction, in consequence of the fever and possibly also of the action of toxic substances, should, so far as possible, be compensated for by food, especially fats and carbohydrates. The diet should consist of milk—cream—oatmeal soup with or without milk, rice soup, sago soup with or without beef-juice or soluble proteids. Eggs are often well borne in soup or in cognac. After the first afebrile week, zwiebach, eggs, scraped meat and roast fowl may successively be permitted. In case of relapse a liquid diet should be resumed. Sufficient liquid should be administered—from two to three quarts a day. The fever may require treatment with cold water, which exerts a favorable influence also on the circulatory and the nervous system and the functions of the kidneys.

LEGALIZING CLAIRVOYANTS.

It is said that there are between eight and ten thousand clairvoyants in Chicago. Whether this is true or not we are not prepared to say, but judging from the number who advertise in the papers and from the number of signs scattered over the city it is quite probable that the number is not overstated. Some of the leaders among them have presented an ordinance to the city council providing that clairvoyants shall hereafter pay a license fee of $800 a year. This is for the purpose of regulating things so that there shall not be as much "promiscuousness" as now seems to prevail; in other words, they desire to limit the number. What a joke it would be if the city council of the great and enlightened city of Chicago should pass this measure and thus legalize this modernized ancient method of swindling! And stranger things have happened in city councils.

A DIPLOMA-MILL ALL RIGHT IN TEXAS.

At last there is an opening for those individuals who bought diplomas from the so-called Independent Medical College of Chicago and from similar institutions. The diploma-mill parchment is just as good as anything else in the great State of Texas, and we may now expect to see these ready-made doctors rush thither. In our Medicolegal Department this week will be found a decision rendered by the Court of Appeals of Texas, which, divested of its legal verbiage, means that when an institution has been chartered by authority of the laws of a State and its charter gives it the right to give out diplomas, Texas recognizes such as genuine, and the holder can practice medicine in that State without infringing on the laws. Accordingly it makes no difference whether a man has studied medicine, whether he has attended a medical college, or, in fact, whether he knows the first principles of medicine or not, if he can show a parchment from a chartered medical college he is all right in Texas.

INTERNATIONAL CONGRESS OF THE MEDICAL PRESS.

The recent International Congress of the Medical Press appears to have been largely given up to discussion of technical and quasi-legal subjects, such as copyright, the author's property in his ideas and the form of their expression, the classification of medical subjects, exchanges, the ethics of advertisements, etc., the use of *noms de plume* by medical writers, etc. Though the program was rather a full one, it happened that some of the promised papers defaulted, or at least were passed or crowded out. The question of advertising puffs appearing as contributed articles was discussed among other matters, and it appears that they suffer abroad from this evil as much as here. The disclaimer, of one or two of the German delegates, of its existing in Germany was undoubtedly honestly made, but our Teutonic brethren suffer at least in one way, their articles are freely used as advertising puffs of German products in this country, and their countrymen engaged in manufactures are especially active in this direction. Another bad practice noticed by the Congress that seems more common abroad than here, is the use of pseudonyms with the prefix "Doctor" attached, and this was condemned by resolution. On the whole the results of the Congress seem to us somewhat disappointing, as there was very much that might have been brought before it that was not. The proposition of an international medical press association to cultivate fraternal relations to represent the common interests and to formulate regulations seems to be a promising one, though there may be difficulties in the way. It is to be regretted that no Americans took part in the discussions, as we think they might have added to their interest.

AGAIN THE QUESTION OF CANCER.

Czerny[1] considers the etiology of malignant tumors in general for the special purpose of pointing out prominently some of the reasons which favor the parasitic theory. In addition to a predisposition, there must be some active and exciting cause of malignant tumors. It is emphasized that cutaneous carcinomas occur almost exclusively in the face and hands and that the covered parts of the skin are nearly always immune; in the digestive tract localization occurs especially in recesses of various kinds, in scars and ulcers; the well-known frequency of carcinoma in the vicinity of orifices may find its reason in the mechanical lesions, the eczemas, fissures, and scars, as well as the uncleanliness of these regions; the genitalia, both male and female, furnish numerous conditions, which may be regarded as of predisposing moment. Czerny lays stress on pedantic cleanliness, especially of some regions, as a probable preventive measure against carcinoma. As regards sarcoma, it is recalled that many forms of this tumor resemble much inflammatory new formations and that a tumor of such varying nature probably does not depend on a single agent, but on several different causes. So far, it can not be said that transplantation experiments lend much support to the parasitic theory of malignant tumors. Undoubted cancerous diseases may undergo a spontaneous retrogression—a fact which should stimulate the search for a specific treatment. Czerny's general conclusion is that such facts as those referred to above speak in favor of cancers being caused by external agencies and that the parasitic theory, though resting on a slender basis, has just as much justification as the other hypothesis and carries with it greater hope for prophylactic and therapeutic measures.

ALLEGED ARMY MEDICAL ABUSE.

A lady, Miss Margaret Astor Chanler, whose name suggests an amateur in philanthropy, according to the press reports, has sent to the War Department a severe criticism of the Army Medical Service in the Philippines, charging that there is a lack of surgeons, a lack of nurses, of medical supplies, etc., and asking that she be allowed at once 500 bed sheets for distribution. Copies of her complaint have been sent also to various persons of social prominence and thus a foundation for a sensational investigation is laid. The Surgeon-General of the Army, to whom the communication was referred by the Secre[illegible] of War, has [illegible] is said, prepared a complete refutation both of the medical service in general and of the specific charges in particular. The original communications of Miss Chanler and Dr. Sternberg's reply have not been given to the public *in extenso*, but the correspondence is said to be spirited. We would be sorry to believe that there are any serious abuses in the army medical arrangements in the far East, but we can easily imagine that one going predisposed to find fault might find a pretext. In the matter of sheets, which seems to be one of the special points of criticism, there might readily be an apparent defectiveness and yet no very serious hardship to anyone, certainly not to a seasoned soldier convalescent. As the charges were made, it is said, only two days after the lady's arrival at Manila, it might possibly be inferred that they are not based on any very wide observation or well-considered experience. In any case, we believe that the medical department will make a good showing in reply to them and we trust that they are only the undigested impressions of a dilettante amateur nurse, too ready to make charges on insufficient evidence. So far as learned, the critic does not specify real abuse other than possibly a deficiency of medical and nursing attendance, which might easily be temporarily unavoidable under special conditions.

CLUB AND LODGE PRACTICE.

In our abstracts of foreign literature in this issue is noticed a paper by a leading Belgian physician, Dr. Cuylits, which was one of the features of the recent Congress of Professional Medicine. In it he lays down a plan to harmonize the interests of the medical profession and certain tendencies of modern life that is at least worthy of consideration. The present is an age of combinations of every kind, all self-interested and liable to be in conflict with other interests. Among these organigations are those created for the sole purpose of preying upon the medical profession, to secure its services at the least possible remuneration. The idea of justice to the doctors never enters into the consideration of these "benevolent" societies; they are not even intelligently selfish, for they do not recognize the fact that a product can not be continuously furnished at too cheap a rate without the quality of suffering in the long run. This evil of club or lodge practice has not yet been fully felt in this country, but it is upon us and has a fertile soil on which to grow. If one-half of the population of Belgium are thus receiving medical care gratuitously, or very nearly so, what are not the possibilities in a country like this, where the medical competition is so much greater and where the profession is in such a disorganized condition? The remedy proposed by Dr. Cuylits—a minimum medical tariff allowed by the profession to members of the benefit societies that admit none capable of paying more, the individual physician's liberty of declining such practice moreover being unrestricted—is worth considering in regions where club practice has already a standing, as in Belgium and Great Britain. In this country, however, it will be better to discourage its beginnings rather than to compromise with it. There is nothing unethical in physicians organizing for their own protection against such attempts to exploit them to their disadvantage, and it is suicidal not to do it where the danger threatens.

GLYCOSACHTHEMIA.

Glycosachthemia is the name proposed by Prichard and Colbeck[1] for the condition of the system due to overloading with carbohydrates and their resultant defective metabolism. We have long assumed that the gouty or lithemic state is due to defective metabolism of nitrogenous substances, but, hitherto, as they remark, the symptoms associated with defective metabolism of nitrogenous bodies have received no distinctive name, except in the extreme cases of glycosuria and diabetes. They think it unnatural, however, that an organism phylogenetically, and actually to a large extent, carnivorous, should be subject only to the evil effects of such diet and not to effects of the excess in other directions certainly not less foreign to its nature. The authors trace up the carbohydrates in the system and take up a single group of the neutralized cleavage products that result, the lactates, as an example, and follow out the pathologic processes that are likely to ensue if the eliminative organs are too severely taxed or any of them are disabled in their normal functions. The symptoms they thus deduce are practically those of rickets in the infant, of rheumatism in the youth and the adult, and diabetes in advanced life. They claim that clinical evidence favors their theory, that it is usually easy to prove a previous excess of carbohydrate food in rickets and of similar indulgence in rheumatism and diabetes. Further support is claimed from the therapeutics of these disorders as the effective measures are those that would be rationally prescribed for carbohydrate saturation. The observations which they have themselves been able to make are clearly in its favor, though they have not yet been able to accumulate sufficient clinical facts to carry much weight. In conclusion, they remark that while they have endeavored to clearly distinguish between lithemia and the condition here described, they have not attempted to indicate the effects of the possible reactions and interactions of their respective metabolites, which must occur in diseased conditions. Their article is a suggestive one, and while the chemistry of the complicated animal laboratory is often vague and speculative and lends itself readily to theory, it appears possible that the ideas here offered may be fruitful. Whether glycosachthemia will take rank with lithemia as a morbid entity and be as prolific of medical literature is doubtful, although it is a question for the future to decide.

Medical News.

The British Medical Association will meet next year at Cheltenham, under the presidency of Dr. G. B. Ferguson of that city.

The agent at the Devil's Lake Indian Reservation in North Dakota has telegraphed the Department of the Interior that smallpox has broken out among the Indians and that there are now twenty-four cases on the reservation.

The Board of Control of the National Red Cross Association, at a meeting in Washington, August 11, discussed the attitude of the Association in case of a declaration of war between China and the allied powers.

---

[1] The Lancet, July 28.

It is probable in this contingency that the association will co-operate with the Red Cross Association of Japan.

Medical men in the employ of the Russian government were forbidden to attend the Polish Congress of Physicians and Naturalists, soon to meet at Waraw. In reply to a protest from the committee of organization of the congress, the war department explained that military medical officers must remain at their posts owing to the pending military operations, and can not be spared to attend any congress at present.

The centenary festival of the Royal College of Surgeons, of England, was celebrated in London July 25 to 27 under the presidency of Sir William MacCormac. Honorary fellowship was conferred on thirty-four eminent surgeons of Europe and America. The honor was acknowledged, on behalf of themselves and their respective national colleagues, by Professors von Bergmann, Durante, W. W. Keen, Lannelongue and Pachoutine. Professor Keen, among other well-selected and pointed remarks, said: "We come to you as representatives of four of our great institutions of learning—from Harvard, hoary with the snows of nearly three centuries, to Johns Hopkins in the lusty youth of less than three decades. As President of the College of Physicians of Philadelphia, I represent also the oldest institution in America at all similar to your own, a corporation which includes surgeons as well as physicians, and which was already in its teens when the Royal College of Surgeons was founded. On behalf of these and all our medical institutions we bring you our heartiest greetings on this festal occasion in the name of sound learning and accurate scholarship. . . . To show you how swift has been our progress and yet how young we are, I need but recall the fact that this college was nearly forty years old before the name of Chicago, now a city of nearly two million people, ever appeared upon the map; and when you were founded, beyond the fringe of civilization on the Atlantic coast the only inhabitants of the vast region from the Alleghanies to the Golden Gate were the buffalo, the bear, and the savage Indian. But though so young, we come not empty-handed. Three great medical advances mark the past hundred years—vaccination, anesthesia and antisepsis. The first and third of these are yours, but the second—anesthesia—is the gift, better than Magian gold and frankincense and myrrh, which to-day America lays on the altar of science. Before that historic date, Oct. 16, 1846, the poor victims of the knife were bound hand and foot and held in the grasp of sturdy men, but hand and cord could not repress the fearful outcries which filled the air. But at Warren's touch the thongs fell off; he spoke, and the stormy billows of this Gennesaret of pain were stilled; the peaceful blessed sleep of ether hushed every cry of pain. Then first was moden surgery made possible, and what was made possible by our Warren was made safe and successful by your Lister—no, not your Lister, but our Lister, for his name belongs to no age and no country, but to humanity. It is therefore with a special fitness that to-day you have conferred your Honorary Fellowship upon the distinguished grandson of him who first demonstrated the blessings of ether to the suffering world."

Leper Colony in the Philippines.—General McArthur has convened a board, consisting of Major Louis M. Maus, surgeon, U. S. A.; Capt. George P. Ahern, Ninth Infantry, and Capt. W. E. Horton, assistant quarmaster, to select an island in the Philippine archipelago for the segregation of lepers, to prepare plans and estimates for suitable buildings thereon and estimates of salaries for the necessary officials and employees. The board is also charged with fixing the ration and other allowances for the support of such leper colony. This action was taken in view of the large number of people in the Philippines afflicted with leprosy, who are reported as a menace to public health.

PENNSYLVANIA.

Two Pittsburg physicians, Drs. R. M. Sands and R. C. Clark, are making a European tour by way of the Azores.

During the past week the number of children sent to the country by the Children's Country Week Association was about 400. They were taken to the different suburban towns.

Henry Hoffman, who is said to have been the oldest resident in Pennsylvania, died at his home in Hazleton on August 8, aged 105 years. He was a woodchopper by occupation.

From August 7 till August 11 the heat which prevailed all over Pennsylvania was most oppressive. In Pittsburg on August 9, 5 deaths resulted from this cause and on the 11th two heat prostrations occurred. The government thermometer registered 98 F. on that day, the highest on record. Other deaths occurred in Reading and Linfield.

The 10,500 soldiers now in camp at Mt. Gretna were threatened a few days ago with a water famine, caused by vandals, who cut the pipes and twisted the spigots, permitting the water to run to waste. Owing to the intense heat which prevailed there, some of the drills were abandoned. On August 7, 200 prostrations were reported. No deaths have so far occurred.

The constitutionality of the Act of Assembly of this State regarding the sale of oleomargarin has been questioned and the Supreme Court of the United States will be called upon to decide the question. This action has been taken by counsel representing a number of offenders against this law, and who have been recently tried and convicted in Philadelphia. The special clause in this act which has been questioned is that which prohibits "the sale of oleomargarin if it contains any coloring matter, and is not free from ingredients which make it look like butter." This clause, it is claimed, is in conflict with the Constitution of the United States.

Philadelphia.

Dr. L. Webster Fox will spend the summer in the woods of Maine.

Dr. Wendell Reber is spending a few weeks at Grand Pré, Nova Scotia.

Messrs. Drexel and Company announce that the total amount of money received by their firm up to August 7 for the Indian Famine Fund is $4,098.16.

During the year the Ayer Clinical Laboratory has been opened and in charge of Dr. Henry W. Cattell, assisted by a corps of workers. The electric plant which has supplanted gas has proved cheaper and more satisfactory.

The report of the Pennsylvania Hospital shows that during the last twelve months 35,195 patients have been treated in the institution; that its income was $754,464.69, and its expenses about $100,000 less.

The number of deaths occurring in this city during the week ending August 11 was 452, an increase of 13 over the previous week, and an increase of 7 over the corresponding period of last year. The principal causes of death were: Apoplexy, 12; cancer, 20; cholera infantum, 47; tuberculosis, 56; suicide, 4; diphtheria, 46 cases, 7 deaths; scarlet fever, 29 cases, 2 deaths.

Members of the Building Committee of the City Hall of Philadelphia are making an estimate of what it would cost to install an ice-water supply from a central source to extend to all the different rooms of that building. The proposed plant is estimated to cool 50,000 gallons of water a day and is expected to cost $45,728.50, exclusive of labor. According to this plan there would be four-inch pipes to carry the water to the seventh floor and one-inch pipes to distribute the water to the different rooms.

During the past week there appears to have been a mild epidemic of catarrhal conjunctivitis or, according to the papers, "pink eye." The disease is attributed primarily to the hot weather and draughts and dust encountered on the trolley cars, which produce cold. The dust is supposed to act as the exciting cause of the conjunctivitis.

The Sanitarium Association reports that during the 44 working days there have been 115,652 persons seeking admission. This is an average of 2628 per day. The adults numbered 15,891; infants, 13,128, and children over 2 years, 86,633. Of bathers there were 14,654 boys, 16,446 girls, and 2466 infants; 61 mothers and infants were admitted to the hospital.

Two ambulance collisions occurred in one day during the past week: The first was that of the St. Joseph's Hospital and was caused by the horses plunging into an excavation in a street crossing and throwing the resident physician, Dr. Butler, to the ground, slightly injuring him. The ambulance was badly damaged. On the same day, while the ambulance of the Germantown Hospital was returning home with a patient, a trolley car filled with children plunged into the ambulance, throwing the horses, which afterward attempted to run away, but were caught by a patrolman.

The 149th annual report of the Pennsylvania Hospital has been issued and is as follows: New patients received in the wards, 4,079; total number treated in the wards, 4,345; patients remaining May, 1900, 274. Patients admitted to receiving ward, 19,174. Number of cases treated in dispensary: surgical, 9,893; medical, 2,466; eye and ear, 2,092; nose and throat, 918; gynecological, 329; mental and nervous, 49; orthopedic, 8; total, 15,755. Total number treated in receiving wards and dispensaries, 35,195. The ambulances have made 1,401 calls during the year. During the past year there were 435 more admitted to the wards of the house and 3,412 more treated in the receiving wards than last year.

ILLINOIS.

Dr. Adams, of Ann Arbor, will succeed Dr. Guy W. O. Mitchenor in his practice in Kansas, Edgar County.

The City Chemist has analyzed the drinking water used at the Midlothian Club, and has found the main supply to be of good quality, and consequently not the cause of the recent cases of alleged typhoid fever.

Dr. John G. Byrne, who served with the Second Illinois Infantry, U.S.V., in the Spanish-American war, and afterward became an acting assistant-surgeon in the army, is reported to have received a wound in the arm at Sinaloan, Luzon, P. I., on July 26.

COUNTY ORGANIZATION.

The spirit of organization is evidently prevailing in this State. Seven new county societies have been established during the last nine months, and as many more it is expected will be organized soon. The officers of the state society are anxious to have an active society in every county in the state.

THE REGENT CASE.

Dr. Michael N. Regent, on August 10, was found guilty of conspiracy to obtain money by false pretenses and was sentenced to imprisonment in the penitentiary and a fine of $1,000. This opens up a history of fraud in fraternal insurance. It is reported that other fraternal insurance societies have been defrauded in a similar way, and that when the prisoner's present indeterminate sentence is concluded he will be held on other charges. Dr. Regent is said originally to have borne the name of Regentovitch, but was authorized to drop the two last syllables of his name, thereby de-Russianizing it. He is a graduate of an electic college of 1888. The crime of which he has been convicted was a fraud on the Knights and Ladies of Security, a fraternal society of which he was medical examiner. In January, 1898, James O'Grady, uncle of a co-defendant, an aged and infirm man, was proposed for membership in Illinois Council. He was examined and passed by Dr. Regent, duly admitted, and a policy issued. On November 28 his death was reported, death proofs filed and the claim paid. O'Grady was still alive and had no knowledge that he had been a member of the order or that his death had been reported. On account of a quarrel over the division of spoils, the matter became public and one of the conspirators, O'Grady's niece, turned State's evidence.

HEALTH DEPARTMENT.

The records of the department show that in the matter of prophecies it is far and away ahead of the official forecaster, for in the bulletin of June 25 it was announced that "there is reason to apprehend that a heated term of unusual intensity will follow"—and it did. The heat instead of being localized in this region, however, was general; even the Lake Superior region sharing in it. The heat wave, which began its march in Australia in 1899, reached the Argentine Republic in January last, in the spring reached continental Europe and Great Britain, and then came to this section via North Dakota. The progress of this heat wave was marked by higher temperature than had been previously recorded, and consequently by an increase in the heat accidents. In Buenos Ayres, for instance, 410 deaths occurred in three days and the temperature in the shade ranged for several weeks from 107 to 117 F. In the heated term, now happily passed, the temperature exceeded 90 F. for eight successive days. The deaths for the week were, however, only 18 in excess of the previously recorded highest mortality, which was for the week ended July 15, 1899. The department attributes this comparatively low mortality to the coolness of the last weeks in July, which retarded the rise of ground temperature, upon which depend so largely the zymotic and hot-weather diseases, especially of infants and children.

The mortality for the week ended August 11 was 577, or 93 more than the preceding week, and 87 more than the corresponding week of 1899. The annual death-rate per thousand was 17.18. Of males, 309, and of females, 268 died. Under 1 year, 190 died; between 1 and 5 years, 85, and over 60 years, 94. The principal causes of death were: Acute intestinal diseases, 172; consumption, 56; nervous diseases, 47; heart diseases 29; cancer, 24; violence, 22; Bright's disease, 18; pneumonia, 18; sunstroke, 14; suicide, 9; typhoid fever, 9; apoplexy, 8.

During the week 611 births were reported; 319 males and 292 females. In the contagious disease division, 16 cases of scarlet fever and 15 of diphtheria were reported. At the stockyards 26,170 pounds of meat were condemned. Specimens of milk numbering 112 were brought to the laboratory, 5.92 per cent. of which were found to be below grade.

MARYLAND.

Thirty-one cases of smallpox have been treated at the quarantine hospital during the spring and summer without a death.

Dr. L. McLane Tiffany, after spending two months at his country place, Mt. Curtis, eastern shore of Virginia, has gone to Beverley Farms, Mass.

There were 137 deaths here in the 5 days from August 5 to 9, inclusive; of these, 43 per cent. were due directly to the excessive heat, which was higher here than at any other place in the country.

In view of the prevalence of typhoid fever, 11 new cases having been reported, the Health Commissioner has given a warning to the citizens to boil the drinking water and filter it through absorbent cotton.

Out of 178 applicants for appointment as patrolmen on the police force, 89 have been rejected by the Board of Police Surgeons. About 25 per cent. failed on account of height, weight, and chest measurement; 2 per cent. on account of eyesight. The principal diseases found were heart disease, Bright's disease, varicose veins, and consumption. Four had flat feet. One, thought to be perfectly sound, showed tubercle bacilli in his sputa. There are many applicants for the vacancy caused by the resignation of Dr. William B. Burch.

ALLEGED CRUELTY IN A SANITARIUM.

The grand jury is investigating a case of alleged cruelty to a young white woman at Dr. Flora A. Brewster's asylum. Dr. Percy M. Wade, of Spring Grove Asylum for the Insane, who has been in charge of 500 patients there for the past ten years, says they have neither chain, handcuffs, muffler, nor even a strait-jacket. But one man is ever confined to his room, and it is necessary in his case because he is given to running away. Among all the criminal insane there are none treated with mechanical restraint. Such patients are treated much like children. There are two attendants in wards of 30 patients, and one in those of 10. In the ward of criminal insane, with 28 cases there are three attendants. At night they sleep 5 to 10 in a room, with an attendant, not in the room, but near at hand. If a patient needs constant watching, an attendant looks after him exclusively. For private cases the charge is $7 per week, and at the Sheppard Asylum a good room can be obtained for $10 per week. Outdoor life is encouraged and many patients work on the farm. Amusements are provided and are looked forward to by the patients with pleasant anticipation.

Dr. Edward N. Brush gives similar testimony at the Sheppard and Enoch Pratt Hospital. He has never seen a strait-jacket except in pictures and has never seen a patient, either male or female, chained. Some medical superintendents have gone to the extent of adopting a rule of absolutely no restraint, but the more conservative agree that restraint is sometimes necessary and humane. If restraint be necessary for the hands it should be an endless sleeve, which confines the hands in front in an easy position; this and the padded cell for frenzied patients are all that are necessary. It is never necessary to have more than one attendant to a patient. except in very violent cases. At the Sheppard there is about one attendant to four patients, but the number could easily be diminished.

Dr. Flora A. Brewster was presented by the grand jury on the 10th inst. for violating the State lunacy law by treating an insane patient without license in her private sanitarium. Dr. Brewster was released on $500 bail. The case will be before the grand jury again when the question of indicting comes up.

MICHIGAN.

Dr. John L. Williams, of Shawnee, Wis., who had practiced for twenty-eight years in that city, has located in Menominee.

Dr. Lewis F. Bleazby, of Detroit, has been appointed acting assistant-surgeon in the army and has started for his post of duty in China.

The medical men of Detroit held a meeting at the Cadillac House on August 16 to organize, if possible, a business association to include physicians of all schools recognized by the medical practice act.

"Doc" Naegele, who had charge of the anatomical laboratory of the University of Michigan for more than half a century, and who made himself an excellent practical anatomist, died at Ann Arbor July 28.

MORTALITY FOR JULY.

There were 2,509 deaths reported to the secretary of state for the month of July, corresponding to a death rate of 12.4 per 1,000 estimated population. This number is 216 more than the number of deaths for the preceding month and 110 more than the number registered for July, 1899. There were 561 deaths of infants under 1 year of age, 141 of children aged from 1 to 4 years and 611 of persons aged 65 years and over. Important causes of death were reported as follows: Consumption, 134; other forms of tuberculosis, 42; typhoid fever, 36; diphtheria and croup, 10; scarlet fever, 18; measles, 14; whooping cough, 28; pneumonia, 84; diarrheal diseases of children under 5 years of age, 278; cerebrospinal meningitis, 24; cancer, 108; accidents and violence, 197. A considerable increase was shown in the proportion of deaths of infants under 1 year of age corresponding to an increase in the number of deaths from diarrheal diseases. All the other causes of death were nearly stationary or showed slight amounts of decrease except pneumonia, which was only about 50 per cent. of that of the preceding month. There were 2918 deaths in Indiana for the month of July, corresponding to a death-rate of 13 per 1000, indicating a considerably greater increase of mortality with the approach of warm weather than attained in Michigan.

OHIO.

Dr. W. C. Mabry, formerly of Cleveland, has been made an acting assistant-surgeon in the army, and will probably be ordered to China.

Dr. A. W. Dummers, Columbus, who was recently appointed an acting assistant-surgeon in the army, has been ordered to Manila via San Francisco.

Dr. F. C. Griffiths, Mount Carmel, is on his way to the Philippine Islands, where he has been ordered as acting assistant-surgeon in the army.

The East Side physicians of Columbus are attempting to form a protective association against the professionals and amateurs who avoid paying bills for medical services.

Dr. J. F. Edwards, Portsmouth, has been appointed acting assistant-surgeon in the army, and has been ordered to report for duty with the 7th Infantry, now on its way to China.

Dr. W. E. Lower, Cleveland, has received an appointment as acting assistant-surgeon in the army and has been notified to report at San Francisco for duty with the United States forces in China.

The young physicians of Columbus are considering the advisability of forming a young physicians' academy of medicine, wherein they can hold informal discussions untrammeled by the older members of the profession.

The heat in Ohio exceeded all records on August 11, when 99 F. was registered in Toledo. Three deaths from sunstroke or heat prostration are reported from that city, 2 from Fremont, 2 from Sandusky, and 1 from Marblehead Junction.

MASSACHUSETTS.

Dr. E. S. Smith has been appointed town physician of Springfield.

Dr. James W. Holland, Springfield, has been appointed acting assistant-surgeon, U. S. Army.

Dr. Bernard F. McGrath, Beverley, sailed for Europe August 9. He expects to be absent a year.

The committee on sewage disposal at Pittsfield presented its plans of intermittent filtration to the state board for its approval.

Dr. D. B. Manchester, Beverley, has gone to Europe for a year's study, and on his return will practice in New York State.

Dr. H. W. Hill, bacteriologist of the board of health, has, according to report, completed an examination of two cultures received from Johns Hopkins University, sent to Baltimore from the University of California, and which were taken from a Chinaman who was supposed to have the bubonic plague. Dr. Hill developed the cultures and inoculated a white rat. The rat died in three days. Afterward the bacilli were taken from the tissue, and the results obtained were typical of bubonic plague. Dr. Hill has forwarded to the University of California his opinion that the bacilli are those of bubonic plague.

NEW JERSEY.

At a meeting of the Burlington Board of Health, held on August 10, the following officers were elected: President, F. S. Carter; treasurer, Dr. G. B. Cassady; secretary and solicitor, Franklin C. Woolman; inspector, William M. Jeffries.

The Public Bath Commission, of Camden, has recently made a visit to the bathhouses of Philadelphia and was so much impressed with their usefulness that it will recommend to the council the erection of a bathhouse for Camden to cost about $6,000. The exact site for this house has not been chosen.

The Trenton Board of Health adopted resolutions declaring tuberculosis an infectious disease and is considering an ordinance compelling physicians to report cases such as is done in the case of smallpox and diphtheria. It has been cited by one of the members that ordinances of a compulsory nature in other states have done but little good and some opposition has been encountered. The Board of Health has agreed that the signs warning people against expectorating in public thoroughfares have not been effective and an ordinance has been introduced making this a criminal offense.

The Orange physicians are charged with being delinquent in making reports of contagious diseases to the local board of health. The births for July were 39 and the deaths 44.

The Governor has appointed Dr. H. W. Elmer, Bridgeton, a member of the State Board of Health to succeed Dr. Franklin D. Gauntt, deceased. Dr. Elmer was graduated from the medical department of the University of Pennsylvania in 1870.

CALIFORNIA.

All except two of the medical inspectors of the state were discharged by order of the state board of health. The two remaining are on duty in Chinatown, San Francisco. The board decided not to declare quarantine against Jackson, Amador county, as the smallpox there is of a mild type and as the cases are segregated.

Extensive sanitary improvements have been made at the Presidio General Hospital which will make it one of the most completely equipped military hospitals in the country. The changes include a complete system of ventilating, steam heating, electric-light plant, laundry, disinfecting apparatus, ice-making machine and refrigerator.

The report of the Los Angeles health office for July shows 134 births. The mortality for the month was 166, the chief causes of death being: specific infectious diseases 31; digestive diseases, 22; respiratory diseases, 21; nervous diseases, 15; constitutional diseases, 16; intoxicants, violence and accidents, 11. The apparent excess of deaths over births is probably due to the failure of physicians and midwives to report births to the health office.

MINNESOTA.

The state examining board caused the arrest of B. F. Felson, Minneapolis, who is charged with practicing medicine without a license.

The third annual commencement of the attendants' and nurses' class at the School for the Feeble-Minded at Faribault, was held on July 27.

The postmaster of St. Paul has put a veto on the appointment of a special post-office physician. Even the fact that Minneapolis is so supplied does not suffice to swerve him.

The house physician and the head nurse of the City Hospital, Minneapolis, who were arraigned for breaking quarantine by Dr. Charles Norred, quarantine officer, were released because of the uncertainty of the officer's exact status.

Hennepin County Medical Society decided, at a meeting August 3, to accept the offer of the Andrus building, of quarters on the tenth floor. This will entail the removal of the library of the society from the public library and rental of the entire eighth floor and the balance of the tenth floor to physicians, dentists or pharmacists.

NEW YORK.

The medical building for the Cornell College of Medicine at Ithaca, which is in process of erection, will cost about $100,000 and will be a model of its kind. When completed Cornell will have facilities for instruction in medicine second to none in the country. A large attendance is already assured.

New York City.

Dr. S. A. Knopf is rusticating in Maine.

Dr. Holbrook Curtis has gone to Europe for the summer.

Dr. Emil Mayer is taking his vacation yachting off the Maine coast and on the northern waters.

The Trustees of St. Catherine's Hospital are endeavoring to raise $12,000, the balance of $30,000 necessary to complete an annex to the building.

On Saturday, August 11 the temperature reached 95, but had ranged above 90 for almost the entire week. On that day 30 persons died from sunstroke or heat exhaustion. During the week the patients between six months and two years of age at the Bellevue Hospital dispensary alone averaged 65 a day.

MONTANA.

Helena has a record for health not excelled in the United States, so says Health Officer Leslie Sulgrove. The June death-rate is said to have been only 1 to the 1000 of population. Of the 13 deaths reported, 6 were males and 7 females; 2 were under 1 year of age, 1 under 5 years and 1 between 50 and 70 years. Consumption caused two deaths.

The Attorney-General, in reply to a question respecting the status of osteopaths, has rendered the following decision: "An osteopath in practicing his calling is liable for the payment of a license. An osteopath, I believe, is amenable to the medical law of this state, and could be prevented from engaging in the practice of osteopathy unless a license was secured to do so from the medical board. The fact, however, that such a license is not secured does not relieve the practitioner from complying with the provisions of the license law."

KENTUCKY.

Dr. Henry E. Tuley, Louisville, is spending his vacation with his family at Woodmont, Conn.

Dr. Thornton Perkins, Louisville, has received an appointment as acting assistant-surgeon in the army.

Drs. H. H. Grant, J. M. Mathews and L. S. McMurtry are in New York City with President-elect C. A. L. Reed of The American Medical Association.

The President of the Lexington Board of Health, Dr. Frank O. Young, was made defendant in a suit for malicious persecution and false arrest filed by Dr. A. P. Taylor, August 3. Dr. Taylor claims $10,000 damages.

INDIANA.

Dr. T. J. Spillman, Jr., has moved from Andersonville to Connersville.

At a meeting of the Terre Haute board of health, a final report was made on the smallpox epidemic and the results thereof. It was announced that all expenses due to the epidemic had been paid.

The Death of four infants at the Orphans' Home at Indianapolis has caused the city board of health to ask the coroner to investigate the matter. The deaths are claimed to have been due to formaldelyde used as a preservative in milk.

KANSAS.

Dr. Nathaniel M. Smith, of Chase, has removed to Marion.

The School of Medicine of Kansas University at Lawrence will occupy the old chemistry building, which is now being remodeled and refitted. It is to be known as "Medical Hall."

Dr. Swan, secretary of the State Board of Health, reports that the smallpox epidemic is practically stamped out. Three cases still exist in Sumner county and two in Shawnee county, but no apprehension regarding the spread of the disease is felt.

MISSOURI.

Dr. Ernest F. Robinson has returned from his army service in the Philippines and will take up the practice of medicine in Kansas City.

The addition to University Medical College, Kansas City, will be completed by October 1. It will be four stories high and will contain the dispensary, a large amphitheater, and chemical, pathologic, and microscopic laboratories.

NEW HAMPSHIRE.

In Manchester, Dr. F. G. La Fontaine was arraigned for practicing medicine without a license from the State Regent. There is a large French population in the city; Dr. La Fontaine is French and his patients are French, and still he was obliged to take an examination in English, an unfamiliar language. He is a graduate of Laval University Medical Department, a highly esteemed Montreal institution.

DISTRICT OF COLUMBIA.

MORE THAN fifty bids have been received by the District Commissioners for a site for the new municipal hospital in Washington, for which $100,000 was appropriated by Congress.

WASHINGTON was the hottest city in the United States on August 11, the official thermometer at the weather bureau registering 101 F. The humidity was fortunately exceedingly low so that few prostrations were reported.

IOWA.

A NEW HOSPITAL, known as the W. C. Graham Protestant Hospital, will soon be opened in Keokuk, in the old Mercy Hospital building. The philanthropy of Mrs. Helen M. Comstock has made the organization of this hospital possible. It will be under the control of Drs. F. B. Dorsey and P. J. Payne, of Keokuk, and Dr. D. D. Nice, of Bowen, Ill., who comprise the board of medical directors.

OKLAHOMA.

DR. W. P. BAKER, of Guthrie, surgeon-general of the territorial militia, a West Point graduate, and a veteran of the Spanish-American war, has been appointed acting assistant-surgeon in the army, and will leave for China in a few days.

LOUISIANA.

THE FOLLOWING New Orleans physicians are taking their summer outings in Europe: Thomas A. Dabney; Felix A. Larne; Felix Formento and C. W. Heitzman.

COLORADO.

DR. C. J. AMMERMAN has been appointed local surgeon of the Colorado Midland Railroad at Colorado City, vice Dr. C. J. Turpin, resigned.

WASHINGTON.

DR. HAMILTON STILLSON, of Seattle, is spending the summer months in Zurich, Switzerland.

CANADA.

THE steamer *Chieftain* of the Calvin Company, Kingston, is under quarantine restrictions at Quebec, a member of the crew having smallpox.

DR. HUGH FLEMING, of the Ottawa Bearer Company, has been appointed A. D. C. to the new Commander of the Canadian Militia, Major-General O'Grady-Haly.

A TELEGRAM from Winnipeg states that smallpox has broken out at the half-breed reserve, south of Killarney, near the United States boundary. Drs. J. T. White and Riddell, of that city, have been appointed medical inspectors at Killarney and Cartwright, respectively.

MEDICAL MILITIA MATTERS IN THE MARITIME PROVINCES.

The undermentioned medical officers are authorized to join the course of instruction to commence at Halifax on August 30: Major J. W. Bridges, A. M. S.; Lieut. A. A. Schoffner, A. M. S.; Surgeon-Major D. A. Campbell, 63d Rifles; Lieut. J. Ross, A. M. S.; Surgeon-Major M. A. Curry, 66th P. L. F.; Surgeon-Major O'Neill, late 17th Field Battery; Surgeon-Major J. Hayes, 93rd Regt.; Capt. J. A. Spoungle, A. M. S.; Capt. H. G. Johnston, A. M. S.; Lieut. E. D. Farrell (supernumerary); Surgeon-Lieut. C. D. Murray, 1st Regt. C. A. (supernumerary); and Surgeon-Lieut. E. A. Kirkpatrick, 66th P. L. F.

THE RECENT HOT SPELL IN TORONTO.

Not for 61 years, with one single exception, has Toronto experienced such extreme high temperature as that which obtained during the past week. Its effects were especially seen in the mortality-rate among children and the aged. From August 4 up to August 9, 72 deaths were reported. In one day, August 9, 25 deaths were reported, of whom 9 were children and 4 over 80 years of age. The normal death-rate in Toronto is 9 per week.

ANNUAL REPORT OF TORONTO'S HEALTH OFFICER.

In the annual report of the Medical Health Officer, which has just been issued from the hands of the printers, much valuable information is given with regard to the health of the city. During the year 598 samples of milk were collected and analyzed. There were 225 cases of typhoid, 1913 of scarlet fever and 458 of diphtheria reported during the year, of which 34, 55, and 82 respectively resulted fatally. The total number of patients of all kinds admittted to the Civic Hospital numbered 804. This included 458 of scarlet fever, 334 of diphtheria, 8 of smallpox, 1 of chicken-pox and 3 of measles. The number of deaths during the year was 58, but 6 who died were moribund when brought to the hospital and expired immediately. The death-rate, including those moribund when admitted, was 6.16 per cent., and excluding them it was 5.48 per cent. The report on diphtheria prepared by Professor Shuttleworth, the city bacteriologist, goes very fully into the nature and duration of this disease; and as evidence that susceptibility is influenced by age, he points out that of the 238 cases of true diphtheria the ages were as follows: 5 years and under, 32.6 per cent.; 5 to 10 years, 29.6 per cent.; 10 to 15 years, 12.7 per cent.; over 15 years, 25 per cent. Thus the oft-repeated statement that children under five years of age are more susceptible here receives confirmation. The deaths were: Under 5 years, 24; 5 to 10 years, 5; 10 to 15 years, 3; and over 15 years, 4. Referring to the invasion of smallpox, the report states that the city has been invaded five times, but the health officer considers "that the two secrets of success in handling this disease in a densely populated community are, first, the capability of accurately diagnosing the disease, and second, the prompt, complete and absolute isolation of those infected and of those who have been exposed to infection."

THE NATIONAL SANITARIUM ASSOCIATION.

Mr. W. J. Gage, the treasurer of this association, has written the mayor of the city that he is authorized to submit to the Council of the City of Toronto, the following proposals: The association above mentioned will undertake to devote the sum of $20,000 toward the erection and equipment of a Toronto Free Sanitarium for the treatment of consumptives, provided the city will give an equal amount for the same purpose. If the city accepts this offer, work will be commenced at once, with a capital of $44,000, as by the legislation of the last session of the provincial parliament $4000 would be available from the exchequer of the Province of Ontario.

London Letter.

THE BRITISH MEDICAL ASSOCIATION.

The sixth-eighth annual meeting of the British Medical Association was opened at the historic old town of Ipswich—famous as the birthplace of Cardinal Wolsley—under the presidency of Dr. William Alfred Elliston. In his address the president alluded to the great progress made by the Association since it met twenty-six years ago in another East Anglian town, Norwich. Then it numbered only 6000 members, now it reaches over 18,000, of whom 4000 are colonial. [A full abstract of the address was published in THE JOURNAL, August 4, p. 290.]

The Address in Medicine was delivered by Dr. Pye-Smith, of Guy's Hospital, who took for his subject "Medicine As a Science and Medicine As an Art." He said: "It has been disputed whether medicine should be regarded as a science or an art; but there is no doubt that the original meaning of medicine, and of the corresponding terms in other languages, is the art of healing. It is the knowledge how to act, not how things happen. Nevertheless, as navigation is founded on astronomy, meteorology and physics; as agriculture rests on botany and geology, so medicine depends on pathology. While medical science without art is inefficient, medical art without science is not only unprogressive but ultimately becomes quackery. The profession has suffered from lack of the inquiring skeptical spirit, and has often been led too easily by authority. The reckless abuse of venesection has led to almost complete disuse of a valuable means of treatment, and the misuse of mercury in syphilis has led to the denial of its unquestionable efficiency. How closely natural science is related to preventive medicine is shown by the history of Jenner, who was a naturalist, and of Pasteur, who was a chemist. The cretinoid condition in adults, discovered by the clinical acumen of Sir William Gull, unintentionally produced by the surgical skill of Kocher and reproduced in animals by Horsley, is now cured by the eminently scientific method of thyroid administration, due to Dr. G. Murray and Dr. Hector Mackenzie. A source of failure in therapeutics is the legion of new remedies of which the eulogiums fill waste-paper baskets. It takes a man long years to learn how to prescribe opium. Why throw away this priceless knowledge to dabble in quack remedies, the very praises of which inspire distrust?

The Address in Surgery, on "The Surgeon in the Nineteenth Century," was delivered by Mr. Frederick Treves. [A full abstract was printed in The Journal, August 4, p. 293.]

In the Section of Pathology, Prof. Klein delivered an address on "Bacteriology in Relation to Pathology." For more than a century inflammation has occupied a host of active minds and was being analyzed in all its elements. It as admitted that with the exception of traumatic agencies, the chief, if not the sole, cause of the changes are microbes, which lead to the abnormal interaction between the vessels and the tissues. Then toxins set up the inflammation. Koch's tuberculin, the diphtheria toxin, the toxins of many other microbes produced in the test-tube and then injected, produce typical inflammation. The same has been shown of the dead protoplasm of many microbes, tubercle, cholera vibrio, bacillus pestis, and others. The greater or lesser number of leucocytes in inflammatory foci is explained by bacteriology. Some inflammations are characterized by copious transudations with few leucocytes, others are associated with their copious accumulation as in suppuration. These facts are explained by chemotaxis. Some microbes or their toxins powerfully attract leucocytes from the blood, others have no such effect or even the reverse—negative chemotaxis. Singularly, necrosis is an effect of toxins. Roux and Yersin have shown that the diphtheria toxin has a powerful necrotic action. Progressive necrosis is due to the action of microbes. In non-microbic necrosis, the necrosis is local and circumscribed, being due to direct action of the noxious agent, thermic, chemical or traumatic, and its action is limited to the parts actually attacked. But in both forms the necrosis appears of the same essential character, namely, coagulation of the protoplasm of the cells, inclusive of the vessels. Until recently it was considered that specificity of cell secretion was one of the fundamental phenomena of normal tissues. Behring, Kitasato, Brieger, Roux, Ehrlich, and others, have shown that under the activity of many pathogenic microbes and their toxins a curious series of secretions takes place, which are as specific as normal ones—specific antitoxins and specific agglutinins. It was further shown that not only bacteria, but also organic substances, such as abrin, ricin, venin, are capable of stimulating the cells to a like production of specific antitoxin.

A discussion, "Influenza, As It Affects the Nervous System," took place in the Section of Medicine; Dr. J. S. Bury opened this discussion. Four types of influenza can be recognized, according to the organ chiefly affected, affecting: 1, mucous membranes; 2, the gastrointestinal tract; 3, the heart; 4, the nervous system exclusively. In all forms the nervous system is profoundly affected, as is evidenced by the pain in the head and back, hyperesthesia, delirium and depression—all symptoms of the effect of toxin on the nervous system. When ordinary nervous symptoms appear absent, careful observation will show others—undue dyspnea in pneumonic cases and tachycardia and bradycardia in heart cases. There are two chief groups of nervous affections—those developing during the febrile stage, such as meninigitis and encephalitis, and those arising later, in which as a rule no organic charges are found. In the first group he distinguishes a comatose and a delirious type. The former is very serious and often ends fatally. In one case hemorrhagic meningoencephalitis was found post-mortem. Cerebal embolism, thrombosis and abscess are also found. The delirious type is common in children. The cord may be attacked with the brain or independently. Every known form of nervous affection—of brain, cord, or nerves—has followed influenza. The peculiarity of the influenza toxin as distinguished from that of diphtheria, is that it affects nervous tissue haphazard and not so much in groups.

Mr. R. J. Godlee said that "Subdiaphragmatic Abscess" is not a disease, but merely a bye-product of some other disease. The extra- and the intra-peritoneal varieties present very different symptoms. None of the symptoms can be described as pathognomonic. In the early stages there may be hiccough, a stitch in the side and friction. The stethoscope is useful in diagnosis. The abscess may give rise to dulness in the lower chest and may be accompanied by cardiac displacement. It may be diagnosed from pleurisy from the fact that the movements of the chest are not impaired and that the upper limit of dulness is not so well defined, and that respiration may be heard below this. In emaciated persons the lower border of the right lung can frequently be seen ascending and descending, which would be quite against the presence of pleurisy. If gas is present—"subdiaphragmatic pneumothorax"—the bell sound may be readily elicited. The tympanitic note may reach upward even as far as the second rib, and yet the respiratory movements of the chest may not be interfered with. The causes of the abscess are: 1, gastric rupture of gastric ulcer with localization of the pus; 2, intestinal rupture of a duodenal ulcer; 3, cecal and appendicular disease; 4, suppuration of hydatid cyst of liver or spleen; 5, abscesses of liver; 6, perinephral abscess; 7, subcutaneous injuries; the abscesses sometimes follow a blow, which probably causes rupture of a pre-existing ulcer; 8, wounds; 9, metastases; 10, caries or necrosis of ribs; 11, thoracic suppuration spreading downward; 12, various causes—actinomycosis, tuberculosis; peritonitis and disease of the pancreas.

"Nasal Obstruction as a Factor in Catarrh of the Throat, Nose and Ear," was discussed by Dr. Scanes Spicer. It is not uncommon to have cases of nasal obstruction of the most trifling kind sent for the adenoid operation, in which the adenoid hyperplasia is absent or insignificant. In most cases of adenoids the postnasal hyperplasia is only a part and often a small part in the pathological condition of the so-called adenoid child. Fractured and deflected bones and cartilages, turbinal enlargements, hypertrophied tonsils pushing up and growing behind the soft palate, stunted nostrils and even vaulted palate, are often far more important features in the case. The failure to recognize this is the cause of the unsatisfactory results which sometimes ensue, if the practitioner has undertaken to bring about a cure by simply removing adenoids. In many children with nasal obstruction no formal adenoid operation need be done with an anesthetic—and its risks are not negligible unless under special circumstances. Many hundreds of adenoid operations are done unnecessarily every year in this country when adenoids are not present, or, if present, are only an insignificant element in the obstruction, which depends mainly upon other causes. The result is failure or only partial success in removing the symptoms of obstruction. An operation for adenoids is often regarded as the termination of the case. It is only the first step toward recovery. The respiratory tract being clear, it has to be used and developed. Respiratory exercises for the expansion of the chest, the removal of articulation and resonance defects, regulation of vaulted palate and crowded teeth, and other defects, may require careful attention.

FRACTURES.

Mr. Howard Marsh, F.R.C.S., president of the Section of Surgery, in his opening address made the following remarks regarding fractures:

The subject of fractures, while so old and familiar that it may appear too hackneyed and barren to be worthy of notice, has, nevertheless, lately felt the influence of modern advance. The Roentgen process secures an accuracy of diagnosis which formerly was often impossible. The aseptic method makes operative interference safe so that when necessary it can be adopted without hesitation. To secure the best results, treatment must be applied not only to the fractured bone itself, but to the neighboring joint and the muscles and other structures of the limb.

TEACHING OF PHARMACOLOGY.

Walter G. Smith, M. D., president of the Section of Pharmacology and Therapeutics, took the above as his subject for the opening address of the section. Comparing the teaching of materia medica and therapeutics of thirty years ago with that of the present time, three features stand out prominently: 1, the retrogression of descriptive materia medica in its restricted meaning; 2, the establishment of special forces in practical pharmacy at the medical schools conducted in suitable laboratories; 3, the development of the scientific investigation of the modes of action of drugs.

A modern course of lectures on materia medica should most certainly be founded on physiology, but practical demonstration of the physico-chemic properties of drugs is still necessary. Simple experiments can be shown in illustration of the more important physiologic and therapeutic properties of drugs, general principles can be laid down, alliances pointed out and broad features sketched, which connect together large numbers of drugs.

The flood-tide of discovery of new synthetic chemic remedies has washed on shore a few treasures but much rubbish of a pseudo-scientific sort. The physician is daily worried with samples and advertisements from competing firms announcing new drugs or novel combinations, and he is tormented during his consulting hours by the visits of agents representing these articles. This most objectionable practice is on the increase and should be stamped out by the medical profession.

TROPICAL DISEASES.

Col. Kenneth MacLeod, M.D., president of the Section of Tropical Diseases, in his opening address, discussed the scope and aim of the work of the section. The Secretary of State for the Colonies has realized more clearly than any of his predecessors the importance of acquiring an education as regards tropical pathology and hygiene. The government of India is also aroused and is taking action in the same direction by encouraging research, training men in bacteriologic method, establishing laboratories, appointing commissions and promoting special investigation.

A knowledge of the pathology and pathogenesis of disease obviously must precede and guide preventive and curative effort. The recent history of malariology is a signal illustration of the dependence of sanitary and therapeutic endeavor on pathologic discovery. Koch has been attacking the plasmodium in the human subject. Sambon and Low are endeavoring to cut the morbific circuit outside of the body. The results of the proceedings of these gentlemen should contribute an important aid to the solution of the question whether the Anopheles is the only medium of malarial infection, and if so, whether this occurs invariably by inoculation.

In the South African war, sun-stroke and sun-fever were very common, but it has been impossible to obtain information whether any considerable number of these cases presented the phenomena of epidemic or communicable "siriasis." Enteric fever is always in grim evidence during war. Perhaps the most urgent question of the hour is how to mitigate its prevalence in the British army, in which in time of peace it causes one-third of the total mortality. The fact of the immunity of the native population in India to typhoid fever is most remarkable. It has been attributed to habituation to minute doses of the contagion, to protection conferred by attacks during infancy and childhood, and to racial resistance acquired in the course of generation through both these influences. Whether a similar immunity can be engendered in European subjects, by a process of inoculation such as that devised by Professor Wright, is a question the reply to which is awaited with eager anxiety. Similar procedures for creating immunity against cholera and plague initiated by Professor Haffkine have been attended with satisfactory results in India.

Dysentery has been very rife in South Africa, but has been as a rule of a mild type and amenable to treatment. In some camps it has been apparently infectious, but we have much to learn concerning the pathology and causation of this disease. In addition to imperfect conservancy, foul water, bad food, alternations of temperature, exposure and fatigue, a muco-enteritis apparently caused by the swallowing of irritative particles of grit has been observed which has been termed "dust colic."

The persistence of plague in India and its appearance for the first time south of the equator are events which deserve special notice. It is curious to note that while in India natives appear to be readily susceptible to the infection of plague, Europeans exhibit a comparative immunity to this disease. The same immunity—a sanitary immunity—is also observable in some places as regards cholera.

The work of this section is not only with exclusively tropical diseases but includes diseases originally tropical which may prevail for a time in extratropical localities and diseases which are not especially tropical but which are liable to be aggravated in prevalence or severity by tropical conditions.

(To be continued.)

Deaths and Obituaries.

Philip Smith Postell, M.D., died August 3, at Plaquemine, La., half an hour after an apoplectic seizure. He was born in Charleston, S. C., in 1836; graduated from the Medical College of the State of South Carolina, at Charleston, in 1858, and served throughout the Civil War as surgeon of the Thirty-fourth Mississippi Infantry, C. V. S. At the close of the war he settled in New Orleans, but removed in 1868 to Plaquemine. He was prominent in medical and educational matters.

Theodore Krauss, M.D., of Saginaw, Mich., died at his home on August 5, at the age of 75 years. He was born in Hesse-Darmstadt, Germany, in 1825, studied at and graduated from the University of Giessen in 1851. He afterward took a post-graduate course at Heidelberg University. He came to America in 1858 and settled in Saginaw in 1862. He was one of the oldest and best-known physicians in the Saginaw Valley.

George G. Shannon, M.D., of Tulare, Cal., died at San Francisco, Cal., August 5, from hemorrhage of the lungs. He was a graduate of the medical department, University of Michigan, and settled in Illinois, but was forced to go to California on account of ill health, and located in Tulare in 1878. He was, at the time of his death, vice-president of the Medical Society of Tulare County.

Calvin A. S. Proser, M.D., of Boise, Idaho, died from ether pneumonia on August 3, aged 36 years. He was a native of Toronto, Ont., but received his medical education in New York, graduating from Bellevue Hospital Medical College in 1887. He practiced a short time in Chicago, but was forced on account of ill health to go to Marquis, Iowa, and thence for the same reason to Boise.

W. C. Leuce, M.D., of Jonesboro, Ill., died August 1, from Bright's disease, aged 56 years. He was graduated from the medical department of the University of Louisville, in 1872. He was a recognized authority on the diseases of southern Illinois, and was superintendent of the Illinois Southern Hospital for the Insane at Anna, during Governor Altgeld's administration.

John F. Burus, M.D., died from meningitis at St. John's Hospital, Long Island City, N. Y., on August 9, aged 35 years. He was graduated from the New York University in 1890. He was visiting surgeon in St. John's Hospital, New York, and Maternity Hospital, and was one time associate superintendent of the Fort Hamilton Asylum.

Isaac M. Getchell, M.D., city physician of Brewer, Me., died August 5, fifty-two hours after receiving an injury from a fall, by which his neck was broken. He was 53 years old, and was a member of the class of 1877, Medical School of Maine.

David S. Mills, M.D., of Pine Bluff, Ark., died August 3, from typhoid fever, at the age of 71 years. He was born in Tennessee, and was one of the earliest settlers in Pine Bluff. He was graduated from Memphis (Tenn.) Medical College in 1852.

G. L. Robinson, M.D., of Lebanon, T[illegible] died August 4, at his home, at the age [illegible] was [illegible]ed from the medical department of the University of Louisville in 1850, and then settled in Lebanon. He served during the Civil War as surgeon of the Seventh Tennessee Infantry.

Cyrus B. Schreiner, M.D., of Mount Lebanon, Pa., committed suicide by cutting his throat while despondent, on July 28. He had been ill for several months, and had given up all hope of recovery. He was 47 years old and was graduated from Long Island Hospital Medical College in 1877.

N. M. Cluck, M.D., an old and respected practitioner of Reagan, Tex., died from paralysis August 1. He was graduated from the medical department of the University of Nashville, Tenn., in 1876.

Elias B. Harris, M.D., a graduate of New York University, 1847, who was well known, particularly during the earlier gold discoveries in California, died in San Francisco, August 7, aged 75 years.

T. R. Wilson, M.D., of Pilot Point, Tex., died from tuberculosis, July 28. He was a graduate of the medical department of the University of Nashville, Tenn., in 1869, and settled in Pilot Point in 1895.

Preston B. Young, M.D., of Farmington, N. H., was found dead in his office on July 31. He was of a famous family of physicians and well upheld its traditions. He was graduated in 1888 from the New York University.

Henry L. Donnelly, M.D., a prominent physician of Latrobe, Pa., died on August 3, from Bright's disease. He was a graduate of Jefferson Medical College in the class of 1853, and served through the Civil War, being mustered out as captain.

John L. Spitzmesser, M.D., of Franklin, Ind., a pioneer physician in that region, died August 8, at the age of 65 years.

Cortland Van Rensselaer Creed, M.D., a graduate of Yale medical school in 1857, died in New Haven, Conn., August 8, aged 63 years.

Charles H. Kelley, M.D., one of the oldest residents of Newark, N. J., died at South Butler, N. Y., July 28, at the age of 75 years.

Sanford G. Riley, M.D., of Hamilton, Ga., died in Atlanta, August 1, at the age of 64. He was graduated from Atlanta Medical College in 1879.

Miscellany.

Intoxication by Alcohol and Ether.—A new beverage, composed of ether and slightly diluted alcohol, which is said to have originated in Galicia, is now being used with disastrous results in many countries of continental Europe.

Schools of Tropical Medicine.—The Liverpool School is coming into prominence by its dispatch of three different expeditions to the tropics for the scientific study of the etiology of malaria, dysentery and yellow fever. The *Lancet* informs us that the government will require a two-months' course at either the Liverpool or London school, for medical officers sent to the African protectorates.

Surgical Epilation Without Razor.—Queirel has found calcium sulphydrate extremely useful in removing hair from the field of surgical operations, according to the *Semaine Méd.* of July 4. It is applied in a thin layer like a paste and rinsed off with tepid water in five minutes, rubbing lightly with a cloth. The hairs wash off with it, leaving the surface smooth, without irritation or inconvenience of any kind, except the rather unpleasant odor of the hydrosulphate, which can be disguised if wished. The hair soon starts to grow again.

Index of Current Medical Literature.—Some time ago The Journal of The American Medical Association adopted a new feature, which must undoubtedly have proved of value to its readers. The title-page, in addition to the usual announcement of original articles, contains a short abstract or analysis of each article. In its department of current medical literature The Journal gives us abstracts or notices of the original papers published in the chief medical periodicals of this and other countries. The index of Vol. xxxiv, recently completed, contains another important innovation. By cataloguing the articles which originally appeared in its own pages, together with those which it has selected or abstracted from its numerous exchanges, it furnishes us, in effect, with an index medicus of American medical literature. This is a laborious enterprise and should be highly appreciated by its readers. Those who, in the past, were accustomed to consult the "Index Medicus" in reviewing the literature of any subject are well aware how much that publication has been missed and will gladly welcome such an index as The Journal has prepared.—*Medical Bulletin* (August).

Societies.

Coming Meetings.

American Academy of Railway Surgeons, St. Paul, Minn., Sept. 5-6.

American Association of Obstetricians and Gynecologists, Louisville, Ky., Sept. 18-20.

American Electro-Therapeutic Association, New York, N. Y., Sept. 25-27.

Medical Society of the State of Pennsylvania, Wilkesbarre, Sept. 18.

The St. Joseph County (Ind.) Medical Society met at South Bend, August 3. Dr. F. J. Lent presented the paper of the evening, on "Adenoids."

The Blair County (Pa.) Medical Society held its annual summer meeting at Wopsononock, at which a revised constitution and bylaws was adopted.

The Medical Association of the Lake Keuka Region held its second annual meeting at Grove Springs Hotel, Lake Keuka, N. Y., August 14 and 15.

The Jackson County (Md.) Medical Society met at Seymour, August 2. Dr. J. K. Ritter read a paper on the "Medical and Surgical Diseases of the Rectum."

The Pan-Handle (Texas) Medical Association will hold its next quarterly meeting at Quanah, September 4 and 5, under the presidency of Dr. David R. Fly, of Amorilla. Dr. Benjamin F. Hart is secretary.

The South-eastern Nebraska Medical Association met at Wymore, July 26, for its quarterly session. The physicians of Wymore entertained their visitors, but did not join the society as it was expected they would.

The Jay County (Ind.) Medical Society held a meeting at Portland on August 10, at which Drs. Richardson and Taylor, Fort Recovery, O., reported some cases of appendicitis and Dr. R. P. Murray, Dunkirk, read a paper on "Obstruction of the Bowels."

The Cecil County (Md.) Medical Society met August 2, at Perryville. Dr. W. T. Skinner, Glasgow, Del., discussed typhoid fever with especial reference to the temperature range, and Dr. A. Robbins, of Newark, state bacteriologist of Delaware, demonstrated the Widal test.

The Decatur (Ill.) Medical Society met on July 26. The papers of the evening were "The Practice of Medicine Fifty Years Ago and Now," by Dr. W. J. Chenoweth, of Decatur; "The Bubonic Plague," by Dr. S. R. May, of Mt. Zion, and "Infantile Diarrhea" by Dr. E. A. Morgan.

The York County (Pa.) Medical Society held its monthly meeting at York City. Dr. Wesley C. Stick, of Glenville occupied the chair. Delegates to the state medical society were elected, after which Dr. J. Clarkson Smith read a paper on "Uric-Acid Diathesis," and Dr. J. C. May, a paper on "Sciatica."

The Berkshire (Mass.) District Medical Society will hold its annual summer meeting at Dr. Paddock's cottage, Pontoosuc Lake, August 30. The topic of the meeting is "Quarantine, Disinfection and Care on the Part of Officials who Have Charge of Infectious and Contagious Diseases." It is hoped to secure uniform rules for quarantine, etc., of these diseases.

The Lehigh Valley Medical Association held its twentieth annual meeting at Reading, Pa., August 16, in conjunction with the meeting of the Berks County Medical Society. Dr. J. Milton Duff, Pittsburg, delivered an address on "Modern Obstetrics;" Dr. I. Cleaver, Reading, the retiring president, considered the "Relation of the Medical Profession and the Physical Culture of Children," and Dr. P. A. Harris, of Paterson, N. J, described "Certain Pathologic Conditions of the Fallopian Tubes of Interest to the General Practitioner."

BRAZILIAN CONGRESS OF MEDICINE AND SURGERY.—The fourth annual congress of the physicians and surgeons of Brazil convened at Rio Janeiro, June 17, with a large attendance, including many non-professional senators and other prominent government officials and scientists. The date coincided with the four hundredth anniversary of the discovery of Brazil. Dr. Guedes de Mello presided. Chapot-Prevost described his operation on the united twins; mentioned in THE JOURNAL, Sept. 16, 1899. Many valuable communications on tropical diseases were presented. Committees were appointed to report at the next congress on the establishment of a sanatorium; on the organization of a congress to arrest the spread of syphilis; on the foundation of a maternity. Another committee was appointed to confer with the public authorities on means to prevent purulent ophthalmia and consequent blindness, and a fifth to solicit from the Legislature measures to complete the constitutional principles of professional liberty.

MISSISSIPPI VALLEY MEDICAL ASSOCIATION.—The next meeting of this Association will be held at Asheville, N. C., October 9-11, under the presidency of Dr. Harold N. Moyer, of Chicago.

The following addresses have been announced: I. N. Love, St. Louis, will deliver the "Address in Medicine," and C. A. Wheaton, St. Paul, the "Address in Surgery."

Papers will be read as follows: L. W. Beardsley, St. Louis, "Canthoplasty in Ophthalmic Practice;" Andrew Timberman, Columbus, O., "The Etiologic Relation of Eye-Strain to Epilepsy;" Otto J. Stein, Chicago, "Middle-Ear Disease in its Relationship to the Cranial Cavity;" George F. Keiper, LaFayette, Ind., "Some Observations Gleaned from Some Recent Cases of Mastoiditis;" Alex. C. Weiner, Chicago, "Treatment of Tuberculosis of the Spine;" A. J. Ochsner, Chicago, "Relation of Appendicitis to Gall-Stones;" B. Brindley Eads, Chicago, "Ventral Hernia Following Laparotomy;" George W. Crile, Cleveland, "Technique for Removal of Tumors of the Neck; George W. Cale, Jr., Springfield, Mo., "A Case of Intermittent Hydrops of the Knee;" James B. Bullitt, Louisville, "Hernia in Man and Animals;" Thomas H. Manley, New York, "Notes on Fractures Contiguous with or Involving the Articulations of the Larger Bone Shafts;" John L. Jelks, Memphis, "The Treatment of Peri-Rectal Abscesses;" Sterling B. Taylor, Columbus, "Obstipation;" J. Rawson Pennington, Chicago, "Simple Operation for Hemorrhoids; Enucleation;" A. B. Cooke, Nashville, "Revelations of the Proctoscope in Health and Disease;" H. O. Walker, Detroit, "Vaginal versus Abdominal Hysterectomy;" R. S. Sutton, Pittsburgh, "Cancer of the Uterus and its Treatment;" C. S. Bacon, Chicago, "The Prevention and Management of Infection of the Breast During Lactation;" J. H. Taylor, Indianapolis, "The Girl at Twelve;" Yeatman Wardlow, Columbus, "Ectopic Gestation;" Emil Ries, Chicago, "Pathology of Chronic Gonorrhea of the Male Sexual Organs; A. Ravogli, Cincinnati, "The Gonococci in the Gonorrheal Secretions;" R. A. Bate, Louisville, "Asthma;" T. D. Crothers, Hartford, "The Curability of Inebriety by Medical Treatment; William O'Neal Mendenhall, Richmond, Ind., "The Determination of Sex;" Frank P. Norbury Jacksonville, Ill., "Pulmbonary Tuberculosis in Infancy and Childhood;" W. H. Bates, New York, "Further Observations on the Clinical Application of the Suprarenal Capsule;" Albert E. Sterne, Indianapolis, "The Association of Diseases;" William Porter, St. Louis, "The Growing Necessity for Sanatoria for the Tubercular;" I. H. Goss, Athens, Ga. "Erichsen's Disease: Does it Exist? Various Injuries Due to Accident;" William F. Barclay, Pittsburgh, "The Philosophy of the Science and Art of Medicine;" J. E. Allaben, Rockford, Ill., "Treatment of Adherent Cysts of the Ovary and Broad Ligament by Incision and Drainage;" L. H. Warner, Brooklyn, "Differential Leucocytosis;" J. G. Carpenter, Stamford, Ky., "Suprapubic Cystotomy for Traumatism, with Median Perineal Drainage."

The First International Congress of the Medical Press.

Paris, July 26-28, 1900.

The leading address delivered at this Congress was by Landouzy, who extolled the medical press. By the federation of its multiple organs it is the universal university, the most powerful and effective of all postgraduate means of instruction. It gives wings to the words of the masters and spreads abroad to the four corners of the globe the Pasteur doctrines, Lister's dressings, new remedies, etc., in less hours than it took months in the days of our fathers. It is to the honor of the medical press that the study of the material interests of the profession, although so legitimate and so urgent, yet did not come in the order of its preoccupations until after the study of its intellectual interests. It is to the honor of the medical press that it sought first to impress a professional ideal, a combination of scientific loyalty, love of truth, independence of character, a broad and tolerant spirit of solidarity and disinterestedness. Nevertheless it is now time that the respectable material interests of physicians should no longer be misunderstood. It is only justice for the medical press to take in hand the interests of a profession which, without attracting attention or being thanked for it, has always shown itself more solicitous of its duties than of its rights. Proclaiming that medicine is the most social of professions—its aim being essentially humanitarian—let us no longer hesitate to claim for it the cessation of the abuses which in every land demand of physicians the very best of themselves for the relief of suffering humanity, while the physician by the nature of his calling is charitable and most easily imposed upon. It is scarcely an exaggeration to call the present methods the systematic exploitation of the medical profession by the state, the commmunity, the lodges and sickness-insurance societies. The vast question of public medical charities is one of the subjects now most engrossing the studies and critiques of the medical press in all countries. This gathering can not fail to cast light on several of the problems whose solution is of far greater importance after all to the public than to the medical press. Our journals should place themselves at the service of the righteous claims our confrères are even now discussing over the way in the First International Congress of Professional Medicine. The medical press owes it to itself to discuss all these professional questions with the same interest as strictly scientific questions. It should step into the arena as the advocate of every professional claim it considers just, whether the claims refer to intellectual or to moral or material interests. They may all be summarized in the motto: truth in science; honesty in art, and security in the profession. Most of the claims of the medical corps seem the more legitimate, as in a well-organized society—a society which glories, and justly, in its benevolent and charitable, its mutual benefit institutions—simple justice requires that the physician should have a professional standing in conformity with the humanitarian duties he imposes upon himself. Duties accomplished and services rendered should place society under obligations to the physician. It is for the medical press to persuade the powers that be and the public at large that in medicine is to be found the means to make men better. It is for the medical press to convince one and all that if the physician is in truth the arbiter and engineer of health a more equitable position should be accorded to him in our justice-demanding society. It is for the medical press to never weary of the task of persuading the authorities and the public that there can never be too large appropriations for charitable assistance and the preservation of the health of the people. Entirely aside from reasons dictated by humanity, society—in each of its members—has motives of personal interest in improving the health of our neighbor, in rendering his diseases less frequent and hastening to cure them. It is for the medical press to consider how best to reconcile the charges incumbent on the state, on the community and on individuals, so that the burden would rest lightly on all and not too heavily on any one. To solve these infinitely great and infinitely difficult problems the medical press of the world must work with untiring zeal, remembering the words of Renaudot, the first medical journalist in France: "The rich must aid the poor, for the harmony of a state ceases when one part grows out of proportion to the rest while another atrophies."

International Congress of Professional Medicine.

Paris, July 23, 1900.

About four hundred physicians and fifty ladies were present at the opening session of the first International Congress of Professional Medicine and Medical Deontology, Paris, July 23. The secretary, J. Glover, observed in his address that for the first time a liberal corporation which makes less noise in the world than the rest, perhaps, but which yet plays one of the most beautiful parts, and whose independent character gives it an absolutely exceptional place in respect to society, has assembled to discuss its duties, chiefly, but also, a little, its rights. It is an ungrateful, arduous task, so delicate is the epidermis of the medical corps and so exquisitely sensitive its nerves, and also so complex is the economic position of the physician in the organization of modern society.

Dr. Landes, president of the Union des Syndicats Medicaux de France, emphasized the value of the capital represented by the physician as he enters on his medical career. This includes not only the special pecuniary expenses of his long and onerous studies but the sum of the disbursements required for the material life of a man already past the middle of average life, and besides—most important of all—the intrinsic value of the man himself, resulting from his moral and scientific capacity, the capital of his accumulated labor. The young physician, therefore, represents a dual capital, a financial and an intellectual value, the total corresponding to a higher figure than that possessed by a man entering upon any other career. And yet the latter protects his capital to the fullest extent, which the former seldom or never does. The manufacturer insures his plant, the merchant his goods, the farmer his buildings, etc., but the physician seldom realizes that all his capital is vested in his own person and that the welfare of his family depends solely upon his health and life.

Jendrassik described the benefits of an organization such as the Hungarian Medical Association, which was founded in Hungary three years ago, and now comprises five-sixths of all the members of the profession in the country. This organization pays a certain sum to the family of a deceased member; has made a special study of legislation affecting physicians in any way; has established a minimum rate for fees and has founded a special journal to keep its members in touch with its work. The resolutions proposed by Cuylits in his address on "Lodge Practice," mentioned on page 460 of this issue, were adopted by the Congress in full, with the exception of the last, which was modified to the effect that the "superintending physician on the board of mutuality" should be a representative of the local medical association.

In discussing the question of hospital abuse, the Congress adopted a resolution that notices should be placarded in the hospitals and dispensaries and outside that they are for the exclusive benefit of the poor, with mention of the necessary formalities. Thiery further advocated that tickets good for one year should be given to needy patients whose circumstances have been investigated by a special committee appointed in each precinct, and that these tickets or information in regard to pecuniary resources of each applicant should be exacted. The latter resolutions were not voted on, as conditions vary so widely in different localities that no general rule will apply to all.

Descouts presented resolutions which were also adopted, affirming that it is the task of medical societies—not individuals—to prosecute persons illegally practicing medicine, and that a special fund must be created for this end, supported by subscriptions proportionate to the needs and consecrated exclusively to this purpose.

The "Abuse of Medico-Pharmaceutic Advertising" was discussed and the resolutions proposed by Richard-Lesay, of Lille, were adopted, as follows: 1. The Congress declares its disapproval of advertising in any way, shape or manner on the part of the medical profession. 2. No pharmaceutic specialty should be allowed to be sold without the formula appended. 3. The rights of medico-pharmaceutic advertising should be much curtailed, allowing them to announce and advertise in medical publications of all kinds, books, reviews, journals, etc., but in medical publications only. 4. Consultations, remedies and treatment are not matters for advertising and are prohibited to any person engaged in the practice of medicine, pharmacy or any branch of the healing art. Lesay's fifth resolution urged the application of legislation to the illegal practice of medicine, imposing a penalty on every unqualified person who by notices, circulars, proclamations or advertising, informs the public that he treats diseases.

Grasset delivered the leading address on "Deontology." He affirmed that ignorance of the principles of deontology is one of the chief factors in the present medical crisis, inasmuch as it discredits physicians and depreciates the profession. He urged the necessity of a general code of deontology and the advisability of a supreme council of professional medicine with moral penalties. Among the acts he condemned are accepting cheques from drug firms for lending one's name to launch a new preparation, or from manufacturers of orthopedic appliances or proprietors of water cures. No physician should be a shareholder in a tuberculosis sanatorium. Sanatoria should be multiplied, but the executive board should be shareholders outside the ranks of practitioners, medical journalists or professors. Some authors have maintained that it is wrong for a physician to speak of his patients as if they were his private property. This view is, however, not generally held. Before accepting a patient as a successor to a confrère, the first physician must be notified of his deposition by the family. As a general principle No. 2 should insist that the family ask for the bill of No. 1 and express intention to pay it. But it is not necessary to wait until payment has been made before commencing to treat the patient. The physician should always accept a consultation, and with the preferred consultant. In respect to homeopaths the question is a difficult one to decide, for if certain ones are frauds others are honest. Dichotomy is to be absolutely condemned.

The Congress voted the resolution to have a Code of Deontology prepared and a supreme council organized with the right to inflict penalties of a professional order. It thus accepted Grasset's views, but extended them to include professional penalties. The latter measure was especially advocated by the Germans. The Congress has thus gone on record as favoring a disciplinary supreme authority, although each country is left free to organize the supreme council and frame its constitution as it thinks best. The *Semaine Méd.* comments that this resolution will probably long remain a dead letter. In order to hasten its consummation the Congress decided—for France alone, of course—that a permanent committee be organized to consist of the board of the present congress and the boards of the Union des Syndicats Médicaux, the Ass. Gén. des Méd. de France, the Syndicat de la Seine and the General Council of the Medical Societies of Paris. This permanent committee is to draw up a Code of Deontology on the bases set forth in Grasset's address, to determine its application in debatable cases submitted by local associations, and to organize another congress of professional medicine. The *Semaine Med.* observes that the morality of the medical corps depends far more on the example afforded by the leaders in the profession than on the vagaries in the ranks. It views with considerable distrust the creation of a disciplinary order as "big with menaces to the individual liberty of the man of art. And if—as is scarcely probable—such a measure should ever be realized, the medical corps may some day begin to lament—like the frogs in the fable—that they had ever asked for a king."

The receptions and other festivities of the Congress were everywhere decorated with the motto adopted: "Optima Medicorum Concordis." The United States was represented among the honorary presidents by Richardson; Great Britain by Wakely and Bruce; Germany by Schwalbe; Austria by Benedikt; Denmark by Bosch; Belgium by Van Dam; Brazil by Moncorvo; Spain by Pascual; Russia by Chapiroff, and France by Brouardel, Cézilly, Lande and Lannelongue. It is proposed to hold another congress in three years, probably in Belgium.

Colorado State Medical Society.

Thirtieth Annual Convention, Denver, June 19-21, 1900.

INFLUENCE OF MYTH AND SUPERSTITION ON MEDICINE.

DR. W. W. REED said that there are now few country neighborhoods that do not have some who are believers in the healing powers of the seventh son of the seventh son. There are in his neighborhood two persons who claim to be able to check a hemorrhage of either man or beast by repeating a certain verse. Why this state of affairs continues is strange; why should a man, who in the conduct of his social, financial, political and religious affairs uses the utmost sagacity and intelligence, when it comes to matters of disease, look for the absurd and the supernatural? He thinks that this is largely due to the fact that medicine in its very incipiency had the misfortune to fall into the hands of the priesthood, who used it largely as a means to work upon the credulity of the people. Charms, mysterious rites and superstitious ceremonies were used in order to impress the human mind, and these have left an influence so strong that it will be many centuries before the effect is eradicated. He advocates the education of the public with regard to the science of medicine and the principles upon which it rests.

RATIONAL TREATMENT OF ABORTION IN COUNTRY PRACTICE.

DR. J. W. CLINE said that in the country, the physician has to assume the responsibility of being anesthetizer, nurse and porter in the midst of uncleanly surroundings, and that "if it is impossible to realize the ideal, we must idealize the real." In inevitable abortion, he gives the patient a dram of ergot and a hypodermic injection of 1/20 gr. of strychnin; cleanses the vagina with bichlorid solution and packs it with iodoform gauze. He orders occasional doses of ergot thereafter. At the second visit, he prepares hot solutions of bichlorid and normal salt, and after removing with placental forceps all that can be removed, he uses a moderately sharp curette. The uterus is douched with bichlorid and then swabbed with Churchill's tincture of iodin, followed by a douche of normal salt solution. He emphasized the advantages of using placental forceps instead of the fingers.

HEADACHE DUE TO EYE-STRAIN.

DR. E. W. STEVENS said that the area affected by disorders of the eye may be defined by a line starting in the region of the nose and following the lower margin of the bony orbit; thence running back from the orbital process of the frontal bone to the upper part of the insertion of the ear, and then dipping to form a curved line ending below the occipital protuberance. The area thus bounded may be further subdivided as follows: The fronto-nasal area, where the pain is said to be an aching over the middle of the forehead to the left or right of the middle line over the supraorbital notch. This area becomes tender in affections of the substance of the cornea, the anterior chamber of the eye, the upper part of the nose and the upper incisor teeth. The midorbital area, where the pain is at the back of the eye "over the front of the hair." This is usually due to refractive error. Contrary to most statements on the headaches of hyperopia and hyperopic astigmatism, he finds that they belong to the morning headaches. Headaches made worse by new work, or those that disappear under the use of atropin are almost always due to eye-strain.

DYSMENORRHEA.

DR. MINNIE C. T. LOVE considers electricity the best treatment for dysmenorrhea. The action of galvanism is almost entirely nutritional, stimulating the lymphatics, increasing the circulation, and acting as a nerve sedative. She recited the histories of fourteen cases, in all of which electricity had proved a remedial measure of great efficacy in various forms of the disease.

MEDICAL AND SURGICAL EXPERIENCES IN EQUATORIAL AFRICA.

DR. ALBERT L. BENNETT said that he opened his medical work in Congo Français in 1898, among the great and powerful tribe of anthropophagi, known as Fang. His residence and hospital was about fifteen miles north of the equator. The first man of these people who took an anesthetic was the village witch-doctor. The operation was a slight one for removal of tubercular glands, but the natives present escaped to town and started the rumor that he killed the medicine man, and was then "cutting him up." Fortunately by the time a large hostile crowd had reached the hospital the patient was out of the anesthetic, and was then able to tell the crowd what a brave man he was. After that everybody wanted "sleep medicine" for the slightest pain, or for domestic trouble. An African chief owning from ten to a hundred wives is not infrequently a much-worried man and eminently deserving of pity. Nervous diseases are extremely rare, doubtless due to their having no care for the morrow. One case, however, deserves attention: Male, 55 years old, having considerable fame as a witch-doctor, owing to the fact that he "picks up fire" without feeling pain. He was greatly emaciated, heart action rapid. The left shoulder presented a large mass of the muscle having sloughed away, leaving a large running sore, which gave forth a most offensive odor. Only the little finger of the right hand remained, the others having been burnt off, the stumps being fairly healed. The history of the case was peculiar. He was found sleeping in the fire into which he had rolled while asleep. Since that time he was looked upon as a great "ngàng an" (witch-doctor), whom fire did not hurt. When making medicine, "biang," he would pick up burning wood and hot ashes. The muscles of the legs and arms were in a state of atrophy; reflexes exaggerated; sense of touch and smell normal, but the thermic sensation was absolutely lost. He died six months after of myelitis and secondary hemorrhage.

The leading symptoms of malarial infection near the equator are headache, nervousness, aching pain in all joints, ophthalmia, and sometimes a most exasperating coryza. He is of the opinion that arsenic is of more value than quinin in the treatment of malarial infection near the equator. Methylene blue is useful in chronic cases only.

Surgical cases are scarce, except senile cataract. During the two years of his sojourn, he had not seen a single case of trachoma. In closing his paper, he reported a case of ligature of the innominate for aneurysm of the right common carotid involving the subclavian. The specimen was exhibited.

DEGENERATIVE RESULTS OF DEFECTIVE HEREDITY.

DR. CHARLES DENISON said that autoinfection from rebreathing respired air causes a lethargy and enfeeblement of the nervous system, which in turn has a deleterious influence, especially on the respiratory system. The will power is also dwarfed by the depressing influences of deficient ventilation and the mind rendered unable to properly appreciate the force of either argument, precept or teaching. The only way to compass the great difficulty is through the systematic incorporation of good ventilation and physical training. He prefers the term "consumption" to "tuberculosis," and defines consumption as a degenerative or slow death, due to the vitiation of the blood, generally produced by deficient ventilation of the lungs, a prominent and advanced sign of which is the bacillus of tuberculosis. The phases of our civilization which aid degeneration and also tuberculosis are: 1. The advance in the healing art, which suspends the law of natural selection and permits the weak to propagate their kind. 2. The stimulation of the intellect and the nervous system to such an extreme as to injure the physical—reproductive—powers and favor sterility. 3. Indoor and inactive life, which is the accompaniment of the present social condition. 4. The self-supporting women, who decrease matrimony and exhaust vital power. 5. The present unaided effort of natural selection.

He formulated the following rule of marriage selection to avoid consumptive offspring: Find the proportion of all the mother's, father's and their married brothers' and sisters' children who were living at 5 years of age; if less than 80 per cent. are alive, there is reason to suspect a weak strain in the lineage; if less than 60 per cent., there is strong proof of degeneracy, etc. If the father or mother or any two of his or her grandparents, uncles, etc., died of consumption, cancer or scrofula, the proof of some defective biology is still more evident. Double this tendency to degeneration by uniting two family lineages equivalent to the above, even if one of the parties is ever so little defective, and a sin will be committed by such marriage. The only concession possible which would permit of such marriages is the non-bearing of children, that this line may end with the lives of the contracting parties. It is asserted that "love is blind," and that, no matter what is said young men will make fools of themselves in choosing a wife, and girls will repeatedly "decline" proper offers of marriage only to pick up a "stick of a man" in the end. Under a proper system of education, and with a discreet enlightenment of the young as to their responsibilities, "love will go where it is sent" and it will be sent to the right place.

DIGESTIVE DISTURBANCES IN PULMONARY TUBERCULOSIS.

Dr. C. B. Vanzant read a paper on "The Causes of and Importance of Digestive Disturbances in Pulmonary Tuberculosis." He considered the subject from the following standpoints. 1. Are dyspeptics more prone to develop tuberculosis than others? 2. Are tuberculous subjects more prone to develop digestive disorders than others? He arrives at an affirmative conclusion regarding the predisposition to one disease when the other is in existence. He laid great stress on the rôle which the diminished HCl of the gastric juice plays in the production of all kinds of fermentative changes, giving rise to toxins, ptomains and toxalbumin, which ultimately reach the lungs and there embarrass respiration. And, conversely, pulmonary tuberculosis predisposes to secondary indigestion by the disturbance of the gastric glands, due to profound anemia, hectic fever and neurasthenia. Dilatation of the stomach is an occasional condition of phthisis. From his observation he believes that a bad digestion is the heaviest burden a pulmonary patient can carry, and that if unrelieved, it will undo climatic, hygienic, medicinal and every other influence that can be brought to bear.

SCARLET FEVER AND QUARANTINE.

Dr. W. A. Kickland formulated his views on the above subject as follows: 1. Cases of scarlet fever should be released from quarantine whenever desquamation is complete. 2. All children, before release from quarantine, should be anointed in the evening with a salve composed of carbolic acid, 2 c.c.; ol. eucalypt., 5 c.c.; and olive-oil, 100; followed in the morning by a thorough soap and water bath. This should be repeated for four successive days. 3. No domestic animals should be allowed in the house during the infective period. 4. There should be some means of compensating the quarantined family for time lost, as the public shuts them up for its own protection. 5. Health officers should be appointed whose compensation should be sufficient to justify them in giving their entire time to the work. They should visit every case of scarlet fever and raise the quarantine whenever they consider it safe.

INFECTION BY THE YEAST FUNGUS.

Dr. C. G. Hickey read a paper entitled "Some Pathological Conditions Characterized by the Presence of the Yeast Fungus," in which he gave an account of three cases of throat infection, in at least one, and probably in all three of which, none of the ordinary pathogenic bacteria, but numerous yeast-cells were in nearly pure culture. In a family of four, the wife had sore throat, from which she recovered, the husband had a fever attack, with intense aching across the back, chill and fever, temperature 101 F., dense exudate, deposit grayish in color, firm and not easily removed, leaving an irritable bleeding surface. The culture report was negative and recovery slow. One of the children then had a high fever, accompanied with vomiting and exudate in the throat; on the same day an eruption appeared, beginning on the chest and spreading over the body. The rash was small, papular, mostly discrete, and could be felt under the skin before it showed on the surface. There was a mild, convulsive seizure on the second day; the throat was not painful, and there was no glandular enlargement. Two cultures which were made proved negative as to diphtheria, but showed the presence of numerous yeast-cells, and the exudate showed a tendency to return. The second child had similar symptoms, but less severe in type. No culture was taken.

GUAIACOL IN DYSURIA.

Dr. Jesse Hawes discussed "The Local Use of Guaiacol in the Treatment of Frequent and Painful Urination." He said that this agent is applicable only in those cases in which the cause of the symptom is located in the extreme inner portion of the urethra. The diagnosis of deep urethritis having been made, guaiacol is applied through a speculum to the affected mucous membrane. It acts as an anesthetic and stimulant, and does not give rise to strangury as does silver nitrate. The patient retains the urine for hours after the application.

SIGNIFICANCE OF THE FORM OF TUBERCLE BACILLUS.

Dr. Henry Sewall read a paper, entitled "A Preliminary Note on the Relation of the Form of the Tubercle Bacillus to the Clinical Aspect of Pulmonary Tuberculosis," in which he stated that he undertook the solution of this problem at the suggestion of Dr. Wm. Welch, of the Johns Hopkins Hospital, and that the work was done under exceptional advantages at the Adirondack Cottage Sanitarium, where more than seventy patients were subjects of the inquiry. He had found that the form of the bacilli has great significance in the discrimination of these classes. The short, deeply-staining rod or chain of rods has fearful import. A rather thick, well-staining, homogeneous rod of moderate length is the usual form in many active cases. The long rods, particularly if irregularly broken, betoken a milder process. The chain of sporeless heads characterizes the very chronic cases, which make us wonder at their tenacious hold of life. If there is a benignant form of bacillus it is a rather long, slender rod, ill-staining, or staining irregularly, as if the body of the microbe were irregularly corroded on the sides. It is found in cases while apparently passing on to cure. Sputa of the same individuals, examined month after month, apparently vary in the bacillary character with the state of the patient as regards the disease.

DIABETES MELLITUS.

Dr. R. F. Graham reported the following cases: A woman, weighing 165 pounds, had diabetes for twenty years. She drank from ten to twenty quarts of water daily. Her brother had died at the age of 25, from diabetes mellitus. She passed ten pints of urine, with a specific gravity of 1006; acid; with no albumin, and no sugar. She had borne three children, in the urine of one of whom, a daughter, aged 20 years, sugar was discovered; the specific gravity was always normal, and the amount of sugar 1 per cent.

The second of the three children suffered from eczema and was circumcised on account of a tight prepuce. His urine irritated the wound and excoriation traveled over pubes, scrotum, buttocks and thighs. The urine was acid, contained no albumin, and .25 per cent. sugar. Two years afterward the urine did not contain any sugar, the specific gravity was 1007, was feebly acid, and contained no albumin. It is evident that heredity is well marked.

PULMONARY EMBOLISM WITH REPORT OF CASES.

Dr. F. E. Waxham said that pulmonary embolism or infarction is due to the plugging of a pulmonary artery by a thrombus and the consequent extravasation of blood into the pulmonary tissue. The author believed the condition much more common than generally supposed, and cited a fatal case, occurring suddenly during the puerperal state, also one during an attack of phlebitis and reported in full, a case terminating favorably after sudden and desperate symptoms occurring a few days after an operation for varicose veins. The reported cases show by far the most common cause to be the dislodgment of a thrombus from the uterine sinuses during the puerperal state. The prognosis is generally unfavorable. Of thirty-five cases collected by Sperling twenty-seven were fatal, and of eighteen collected by the author, nine ended fatally. The symptoms vary according to the size and situation of the infarction. Small infarctions give rise to few or no symptoms, and the diagnosis is extremely doubtful. Well-marked cases are attended by sudden and intense dyspnea, rapid and shallow respiration; weak, rapid and thready pulse; pallor, anxiety, cool, moist skin, restlessness, short, painful cough and the expectoration of pure blood in small masses, followed by mucoid expectoration streaked with blood. When situated near the pleural surface and of considerable size, dulness, bronchial respiration, and increased fremitus can be detected. Suddenly fatal cases are often attended by frantic efforts at respiration, intense dyspnea and collapse, sometimes convulsions. When the symptoms enumerated occur suddenly during the puerperal state, during an attack of acute or chronic endocarditis or after operations upon veins, or during an attack of phlebitis we can be well assured of the diagnosis. The author submitted a tabulated record of reported cases.

DISLOCATION AND FRACTURE OF HUMERUS.

Dr. C. B. Lyman presented a paper entitled "Dislocation of the Humerus Complicated by Fracture at or Near the Surgical Neck," of which he said that he had found only 119 cases reported. The injury is an important one on account of the difficulties encountered in treatment and the very serious impairment of function resulting in a majority of cases. The subcoracoid variety makes up 75 per cent. of all cases. The seat of fracture was in the surgical neck in 73 per cent. of these, and the anatomical neck in 22 per cent. He reported the following cases: 1. A tree fell on a man, striking the right shoulder, and producing dislocation of the shoulder and fracture of surgical neck of the humerus. Attempt at reduction by the attending physician was unsuccessful. Splints were applied for ten weeks, but only partial union was secured. One year afterward, he cut down upon the fragments, resected the ends, and secured them by means of silver wiring and plaster-of-paris dressing from neck to hand. Perfect union was secured and also free motion of the bone in its new position underneath the coracoid process. The man works now as line repairer in a telephone company.

2. A miner fell down a shaft in a mine, fifty feet, striking timbers on the way, and causing numerous contusions over the body and dislocation of the right shoulder-joint. Attempts at reduction failed. Seven days after the accident the man came under his observation, and subcoracoid dislocation of humerus was found. He cut down upon the fracture and grasped the lower end of the upper fragment with forceps, and by exerting traction in a line at right angles to the body, succeeded with a slight pull in reducing the dislocation. The fracture was adjusted and held in position with silver wire.

3. A man thrown from a wagon, on examination showed the head of the left humerus lying underneath the coracoid process, and from mobility of his arm there was apparently a false joint below the glenoid cavity. Attempts were made to reduce the dislocation under ether by pressure and traction, without success. The procedure as previously described was used and recovery followed.

(To be continued.)

Therapeutics.

Tinea Sycosis—Barber's Itch.

℞.	Acidi tannici		
	Sulphuris precipitati āā	gr. xlv	3
	Zinci oxidi	ʒiss	6
	Amyli, āā	ʒiv	16
	Vaselini	℥i	32

M. Sig. To be used twice daily.

℞.	Acidi carbolici	gr. v-x		3-6
	Acidi tannici pulv	ʒss	2	
	Glyceriti tannini	ʒss	2	
	Sulphuris precipitati	ʒss-ii	2-8	
	Unguenti aquæ rosæ	℥i	32	

M. Sig. To be thoroughly applied as early in the evening as possible and left on as much of the time as possible.

This ointment is very highly recommended by L. D. Bulkley, of New York City. It may be strengthened in chronic cases by the addition of unguentum hydrargyri oxidi rubri, ʒi to ʒii.

Soft Chancre.

℞.	Acidi borici	gr. xv	1
	Aquæ	℥i	32
	Alcoholis	℥ii	64

M. Sig. To be used for cleansing purposes when a balanitis is present; then apply the following paste for the destruction of the chancre:

℞.	Zinci chloridi	gr. xv	1
	Zinci oxidi	ʒiiss	10
	Aquæ destil., q. s. to make a paste.		

M. Ft. unguentum. Sig. Apply to the chancre and leave in place for twenty-four hours.

The above treatment is recommended by MM. Hallopeau and Lerride in their book on dermatology.

—*Journal des Practiciens.*

Melazyo, in the *Bulletin Médical de Quebec*, for May, recommends dusting the surface of the chancre with finely pulverized nitrate of lead—plumbi nitras—a crust is formed which becomes detached after thirty-six hours, leaving a simple wound which heals promptly.

CHANCROIDS.

℞.	Acidi borici		
	Zinci sulphatis, āā	ʒi	4
	Tinct. opii	℥ii	64
	Aquæ rosæ, q. s. ad	℥iv	128

M. Ft. lotio. Sig. As a local application two or three times a day.

Chronic Laryngitis.

℞.	Thymol	gr. xv	1	
	Eucalyptol	gr. xx	1	33
	Creosoti	ʒii	8	
	Ol. gaultheriæ	ʒi	4	
	Ol. pini sylvestris	ʒv	20	

M. Sig. Inhale five or six drops four or five times a day.

Goiter.

℞.	Iodini (crystals)	gr. ii		12
	Potassii iodidi	gr. iv		25
	Alcoholis	ʒi	4	
	Syrupi simplicis	ʒi	4	
	Aquæ destil	℥ii	64	

M. Sig. One teaspoonful in water one hour after eating, three times a day.

Pediculosis Pubis.

℞.	Hydrargyri chloridi corrosivi	gr. i		06
	Aluminis	gr. xx	1	33
	Amyli	ʒii	8	
	Aquæ q. s. ad	℥iv	128	

M. Sig. Apply locally three or four times a day.

Ringworm—Tinea Circinata.

℞.	Hydrargyri ammoniati		
	Sulphuris loti, āā	ʒi	4
	Vaselini	℥i	32

M. Sig. Apply locally to the affected part night and morning.

Warts—Verrucae.

℞.	Acidi salicylici		
	Alcoholis, āā	ʒi	4
	Aetheris sulphurici	ʒii	8
	Collodion, q. s. ad	℥i	32

M. Sig. To be painted upon the warts daily.

It is the consensus of opinion that some preparation containing salicylic acid is the best for the removal of warts.

℞.	Paroformi	gr. xlv	3
	Collodion, q. s. ad	℥i	32

M. Sig. Apply locally to the warts night and morning.

Dr. Mense, in the *Medical Review*, recommends paraform on account of its penetrative power. It is a white crystalline solid with the formula $(HCOH)_3$ and is sometimes recommended as an antiseptic in doses of .5 to 1 gm. in diseases of the intestinal tract.

℞.	Tinct. iodini	℥i	32

Sig. Take ten drops in a wineglass of water three times a day.

This preparation of iodin is regarded by Murrell, of London, as the best remedy in ulcer of the stomach.

Paralysis Agitans.

℞. Tablets hyoscinæ hydrobromatis, āā...gr. 1/200

No. xv. Sig. One tablet, hypodermatically once or twice daily.

Erb has had success with this preparation in so diminishing the tremor of paralysis agitans that the patient is able to work. In this connection it is well *to bear in mind that the* other alkaloid of hyoscyamus is hyoscyamina hydrobromas, which can be given in double the sized dose of hyoscin.

Fetid Breath.

℞.	Sodii bicarbonatis		
	Saccharin		
	Acidi salicylici, āā	ʒss	2
	Alcoholis, q. s. ad	℥iii	96

M. Sig. One teaspoonful in a glass of water as a mouth wash.

Sweating of the Hands.

℞.	Sodii boratis (borax)	ʒiv	16	
	Acidi borici	ʒi	4	
	Acidi salicylici	ʒiv	16	
	Glycerini			
	Alcoholis diluti, āā	℥ii	64	

M. Sig. Apply with friction three or four tims a day.

—*Journal de Méd de Paris.*

Chronic Parenchymatous Nephritis.

℞.	Tinct. cantharidis	m. xxiv	1	5
	Liq. ferri et ammonii acetatis, q. s. ad.	℥iii	96	

M. Sig. One teaspoonful every four hours as a diuretic.

Salinger recommends this prescription as a valuable diuretic and curable remedy in chronic parenchymatous nephritis. He records cases in which the amount of urine per diem was greatly increased. He emphasizes the importance of giving the cantharides, in small doses, so as not to produce irritation.

Cracked Nipples.

℞.	Potassii permanganatis	gr. xlv	3	
	Aquæ destil., q. s. ad	℥iii	96	

M. Sig. Apply to the nipples several times a day.

Dr. Arthur Giles recommends this preparation in case of cracked nipples, and states the parts heal under this treatment in about eight days. The nipples should be washed in warm water after each nursing.

℞.	Orthoformi	gr. xlv	3	
	Lanolini, q. s. ad	℥i	32	

M. Ft. unguentum. Sig. To be applied locally to the nipples night and morning.

To Cleanse the Mouth.

℞.	Tinct. myrrhæ			
	Tinct. capsici, āā	ʒi	4	
	Aquæ destil., q. s. ad	℥iv	128	

M. Sig. Use as a mouth wash four or five time a day.

Stomatitis.

℞.	Acidi borici	ʒiii	12	
	Tinct. benzoini	ʒiss	6	
	Aquæ destil	℥i	32	
	Syrupi simplicis, q. s. ad	℥iv	128	

M. Sig. Locally in the mouth four or five times during the day.

℞.	Potassii chloratis	gr. xv	1	
	Aquæ destil	℥iiss	80	
	Syrupi rubi idæi, q. s. ad	℥iii	96	

M. Sig. One teaspoonful to be taken internally every two hours.

Laxative for Children.

℞.	Pulveris rhei	gr. xxiv	1	50
	Sodii bicarbonatis	ʒi	4	
	Pulveris ipecacuanhæ	gr. iv		25
	Syrup simplicis, q. s. ad	℥iv	128	

M. Sig. One teaspoonful every three hours until the bowels move.

For a child of 6 years, or older.

Gastralgia.

℞.	Codeinæ phosphatis	gr. 1/4		015
	Bismuthi subnitratis	gr. v		30
	Sacchari lactis	gr. iii		18

M. Sig. At one dose. To be repeated every two hours until relieved.

Leucorrhea.

℞.	Acidi tannici	ʒv	20	
	Alcoholis	ʒiii	12	
	Creosoti	ʒii	8	
	Aquæ, q. s. ad	℥iv	128	

M. Sig. Teaspoonful to a quart of warm water as a douche three times a day.

Toothache.

℞.	Chloroformi			
	Linim. aconiti			
	Tinct. capsici, āā	m. xxx	2	
	Ol. caryophylli			
	Camphoræ, āā	m. xx	1	33

M. Sig. Apply a few drops on pledget of cotton.

—*Bulletin Gen. de Thérapie.*

Eczema of the Scalp.

℞.	Acidi salicylici	gr. vi		36
	Menthol	gr. xii		72
	Ol. lini			
	Aquæ calcis, āā	℥i	32	

M. Sig. Apply externally to the scalp night and morning.

—*Steinhardt.*

Itching of Jaundice.

℞.	Icthyoli	ʒii	8	
	Spiritus vini recti	℥ii	64	
	Aetheris, q. s. ad	℥iv	128	

M. Ft. lotio. Sig. To be used externally for the itching.

Painful Menstruation.

℞.	Codeinæ	gr. ii		12
	Chloralis hydratis			
	Sodii bromidi, āā	ʒss	2	
	Aquæ camphoræ	℥ii	64	

M. Sig. One dessertspoonful in water upon retiring at night.

Styptic for Bleeding Gums.

℞.	Tinct. krameriæ	ʒi	4	
	Chloroformi	m. viii		5
	Acidi tannici			
	Menthol, āā	gr. iv		24
	Aquæ destil	℥ii	64	

M. Sig. Apply locally.

—*Viau, in Med. Record.*

Epistaxis.

R.	Alumnol	ʒi	4	
	Aquæ destil., q. s. ad	℥ii	64	

M. Sig. Use as a spray to check the hemorrhage.

Alumnol is obtained by a reaction between a barium compound and aluminum sulphate. It is a white powder, very soluble in water or glycerin. It is incompatible with alkaline solutions, the hydrate of alumina being precipitated.

Poison from Rhus Toxicodendron—Poison Vine.

℞.	Sodii sulphitis	ʒi	4	
	Glycerini	℥ss	16	
	Aquæ camphoræ, q. s. ad	℥iv	128	

M. Ft. lotio. Sig. Apply locally to the affected part by means of sterilized gauze.

Medicolegal.

No Set Form of Words Required.—According to the Court of Criminal Appeals of Texas, in Winfrey vs. State, no set form of words should be required in a dying declaration to show that the declarant was under belief of speedily impending death. The court, it holds, must draw a rational conclusion from all that was said, taken in connection with such surrounding circumstances as must have been known to the declarant, as to whether he was in such a condition of mind as would render his declaration competent.

Can Show Dog Bite to be Worse than Cut.—The Supreme Court of Iowa holds in Sanders vs. O'Callaghan that in an action brought to recover damages for injuries resulting from the bite of a dog it may be shown by medical experts that the wound made by a dog is more painful to a patient than one made by a clean instrument. Likewise, it holds that it may be shown that the two classes of wounds would be treated differently, and that such witnesses may be asked as to what is the usual and ordinary effect of a dog bite, even when there is no evidence that any poison was injected thereby, it being shown that the wound in question was slow of healing.

Held to Have Had Testamentary Capacity.—In re Hewitt's Will it is stated that the will was executed according to legal forms in one of the intervals between the periodic attacks of drunkenness to which the testatrix was subject, and at a time when she had been sober for about three or four weeks. The evidence was substantially uncontradicted that during her intervals of sobriety she appeared to be rational, and conversed intelligently on many subjects. But to sustain the contest several reputable physicians were called as witnesses. One of these never knew the testatrix, and judged of her mental capacity from an autopsy made by him on her remains. The others saw her only while she was greatly intoxicated, or suffering acutely from alcoholic excesses. The conclusion from all the evidence reached by the Surrogate's Court of New York County, New York, is that at the time the will was executed the testatrix was of sufficient testamentary capacity. The opinions of the medical experts as to what her condition probably would be at other times than when she was intoxicated or suffering from alcoholic excesses, it holds, could not be suffered to override direct evidence of what that condition then actually was.

Examiner's Knowledge of Prior Application.—An applicant for fraternal benefit insurance, who warranted every statement made by him in his application to be true, stated therein that he had never before applied for membership in that order. The application was approved by the medical examiner-in-chief. But when suit was brought by the beneficiary to recover the insurance the association set up a breach of warranty, and showed that about five years before the date of the application the insured had made a previous application to a different subordinate branch, and that such application had been rejected by the medical examiner-in-chief. To meet this line of defense, it was argued that the examiner-in-chief at the time he approved the application for the certificate in suit knew, or was chargeable with knowledge, of the prior application and rejection; that his knowledge was to be deemed the knowledge of the association; and that, therefore, the latter, having issued the certificate and received the assessments thereon with full knowledge of facts that would render it void, should not be permitted to defeat a recovery by proving such facts. This view was adopted by the trial court. The third appellate division of the Supreme Court of New York, however, rejects it, and reverses the judgment of the court below rendered in the beneficiary's favor. Even assuming that the medical examiner-in-chief knew, when he approved the second application, the circumstances of the previous transaction, the court holds, Desmond vs. Supreme Council, Catholic Benevolent Legion, that his knowledge was not chargeable to the association, and that it had the right to avail itself of the defense of breach of warranty. Of course, it is left to be inferred, it might be otherwise, if his action had been more than a preliminary step in the transaction, and if it had been a part of his duty to issue or deliver the certificate.

Waiver of Privilege in Action for Services.—In an action brought by a physician to recover for medical services a counterclaim for damages was set up, the defendant and his wife testified as to his symptoms and treatment during his entire sickness, and he called as witnesses two surgeons who testified that they were called, and found him suffering from a disease other than that for which the plaintiff had been treating him, and performed two operations upon him, after which he speedily rcovered. Then the plaintiff called as witnesses two physicians who had been called in consultation, by the defendant's consent, but at different times, before the two surgeons mentioned were called in. The evidence of these two physicians as to their interviews with the defendant, and what they then learned, was strenuously objected to by him as privileged and inadmissible under the statute. But not so thinks Judge Dunmore. He holds, Hennessy vs. Kelley, in Oneida County Court, New York, that, as applied to the facts of this case, the decisions seem to be that the defendant had the right to insist that all the physicians who attended him should remain silent as to his ailments, and as to any personal communications between him and them of a confidential nature. But when he testified in his own behalf as to the way he had been treated by the different physicians, gave conversations, between him and them, uncovered the maladies from which he was suffering, both by his own testimony and that of other witnesses, including that of two of the physicians who attended him, he waived the privilege as to the remaining physicians in reference to the matters disclosed. He then uncovered and made public what before was private and confidential. It amounted to a consent on his part that all who were present and participated in the various transactions disclosed might speak freely as to what took place. When a waiver is once made, it is general, and not special, and its effect can not be limited to a particular purpose or a particular person. After the information has once been made public, no further injury can be inflicted upon such rights and interests of the patient as the statute was intended to protect, by its repetition at another time or by another person. The rule contended for by the defendant, the court says, would leave a physician absolutely at the mercy of an unscrupulous patient.

Unvaccinated Pupils in Schools.—Section 24 of chapter 45 of the session laws of Utah of 1899 provides: "Local boards of health shall have jurisdiction in all matters pertaining to the preservation of the health of those in attendance upon the public and private schools in the city, to which end it is hereby made the duty of each of the local boards of health: To exclude from said schools any person, including teachers, suffering with any contagious or infectious disease, whether acute or chronic, or liable to convey such disease to those in attendance," etc. Does this confer authority upon such a board of health to prescribe and enforce a rule excluding unvaccinated pupils from school during the prevalence of smallpox, and so long as the emergency continues? The Supreme Court of Utah holds that it does, in the mandamus case of the State, on the relation of John E. Cox vs. the Board of Education of Salt Lake City. That is to say, it holds that authority to exclude those who are "liable to convey" such infectious disease as smallpox to those in attendance on the public schools empowers a local board of health to exclude all unvaccinated pupils from the public schools while the disease of smallpox is prevalent and an emergency on account thereof exists. More than that, it pronounces it a reasonable regulation in aid of the promotion of the public health for such board of health to prohibit all unvaccinated pupils from attending and meeting together in the public schools at such a time. In other words, it holds that, where no attempt is made on the part of the board of health to compel vaccination, but during the emergency an option is given the pupil, who is liable to convey the disease into the schools, to be vaccinated or remain away from the schools until the danger from smallpox is past, the order is justified under the police power inherent in the state, and such power is delegated by statute. However, the court says that compulsory vaccination is not authorized by the statute, and that this holding must not be construed as empowering the board to require compulsory vaccination without the consent of the patient. On the other hand, it holds that, although the constitution of the State of Utah is silent on the subject of controlling contagious diseases, no one person has the legal right to infect another with smallpox, and that the statute can not be construed as conferring that right upon any person or class of people. All boards of health, it also says, have general power under the statute to promptly and effectually protect all persons from impending pestilence and disease. But the exercise of the power is controlled, and, when called upon, the board must show that its acts are justified by the facts in the case.

Not Liable for Injury from Examination.—In the case of Pearl vs. the West End Street Railway Company it was sought to charge the company with the alleged results of a doctor's examination of the plaintiff. The plaintiff had had an accident, and had sued the company, whereupon the latter forthwith sent a doctor to examine him. The plaintiff's trouble was in his left leg, and the doctor, after directing him to stand upon his right leg told him to stand upon his left leg. The man said that he could not, and his own doctor also said that he could not bear his weight on that leg. The examining doctor then told him to "try standing on his left leg." He tried it, fell, and here attributed subsequent hysterical trouble to that cause. Under these circumstances, the Supreme Judicial Court of Massachusetts holds that a verdict was properly directed in favor of the company. It says that it would be a strong thing to say that the evidence warranted finding any one responsible for the accident except the plaintiff himself. The doctor's request that he should try standing on his left leg was not medical advice or direction upon a matter as to which the plaintiff had put himself in the doctor's hands. On the contrary, it came from one who avowedly was in an adverse interest, and who had no authority of any kind. Furthermore, it recognized in its very words that perhaps the man was right in thinking that he could not stand in that way. It only called on him for an experiment in a region of admitted doubt. How far the experiment should go necessarily was left to the man himself when he should make it. If he carried it too far, the doctor was not to blame. Moreover, the court holds, the doctor was not an agent or servant of the company in making his examination. He was an independent contractor. There is, the court continues, no more distinct calling than that of the doctor, and none in which the employee is more distinctly free from the control or direction of his employer. In this case, the doctor was informing himself, according to the suggestions of his own judgment, in order to advise and perhaps to testify for the company. And, it must be assumed, in the absence of other evidence than his profession and purpose, the court adds, that what he should do and how he should do it was left wholly to him. Nor does it consider material the exclusion of evidence that went to the general skill of the doctor's examination, the ground of the claim being a specific fact, definitely stated. Besides all of which, it rejects, as not maintainable, an argument drawn from the liability of a litigant for his attorney. The liability of client for attorney, it explains, is the result of a special series of events, and can not be allowed to found a general rule.

Texas View of an Accredited Medical College.—The Court of Criminal Appeals of Texas finds error in the conviction, in the case of Aldenhoven vs. State, of a holder of a diploma from the Independent Medical College of unlawfully practicing medicine in Gonzales county, for pay, without first having obtained a certificate of professional qualification from the authorized board of medical examiners, and without having a diploma from some accredited medical college chartered by the legislature of the state, or its authority, in which the same is situated. At the trial, the state introduced as witnesses several physicians who testified that the Independent Medical College was not on the list of accredited medical colleges. This was objected to because it was the opinion of the witnesses, and because their opinion was based upon hearsay, and not upon proper information, they having stated that their authority for saying that said medical college was not an accredited one was Polk's Medical Register, a book published by a private concern, and not by any state or medical board created by any state. The court holds that the objection was well taken. It holds that this testimony was clearly inadmissible for any purpose. It says that it was the opinion of witnesses, and was hearsay of hearsay. It was not shown that Polk's Medical Register was any other than hearsay, and the mere fact that it was a book purporting to give a list of accredited medical colleges, the court continues, would not make it admissible. Furthermore, the court holds that the opinion of witnesses as to whether this particular college was an accredited medical college was not admissible, since the state statute itself defines the term "accredited medical college." It refers to article 438 of the penal code of Texas, which provides for the punishment by fine, "if any person shall practice for pay, or as a regular practitioner, medicine, in this state, in any of its branches or departments, or offer or attempt to practice without first having obtained a certificate of professional qualification from some authorized board of medical examiners or without having a diploma from some accredited medical college, chartered by the legislature of the state or its authority, in which the same is situated." Under this article, the court holds, a person is not required to have a certificate of qualification from authorized medical examiners, and also a diploma; in order to free him from a prosecution, but if he has either, he is not subject to prosecution. And the latter clause of the article, the court takes it, is a clear definition as to what the statute means by the term "accredited medical college;" that is, an accredited medical college, within the terms of this article, means a college "chartered by the legislature of the state, or its authority, in which the same is situated." Hence, the court holds, if a party has a diploma from such a college, then he will not be subject to a prosecution for violating this article, and, if he has not, he can be so prosecuted.

1. **Cancer of the Stomach and Intestine.**—The outcome of operations for the cure of cancer of the stomach is difficult to state, but is certainly encouraging. The dangers of resection seem to be lessening, and the limitations that were put upon the operation by surgeons formerly are being removed by modern experience. The size of the tumor seems to be of comparatively less importance, as the whole stomach has been extirpated, and the presence of adhesions with modern methods only prolongs the operation. The presence of enlarged glands is not an absolute contraindication, for it has been found sometimes that they are not carcinomatous. It is important that an early diagnosis should be made for the safety of the patient, and where no tumor is found this is sometimes difficult. If, as Hemmeter, says, rapid emaciation takes place, with stomach symptoms, absence of hydrochloric acid, with presence of lactic acid, while the power of digesting albumin has been reduced under 30 per cent. of the normal, the Oppler-Boas bacillus is found and no improvement occurs from medical treatment for several weeks, it may be assumed that cancer

is present. The modern indications for operation are: 1, presence of tumor; 2, dilatation of stomach; 3, obstructive vomiting; 4, chemical changes in the gastric contents, even where the symptoms are slight; 5, hematemesis; 6, severe gastric pain. All these might indicate only benign disease, but even in that case, operation might be advisable. Curtis reports three cases of operation with benefit and calls attention to the relations of chronic ulcer to carcinoma. It is probable that if a thorough study of the cases is made, severe gastric lesions will be found to have existed long before malignant disease commenced. He believes that operation should be advised even if the diagnosis is not altogether certain and that it will probably reveal in any case some definite conditions which can be relieved. Even if the case is of long duration, and seems unfavorable, there is still a possibility that laparotomy may bring out something to the patient's advantage and improve his chances. Carcinoma of the intestine is next taken up and the differential diagnosis is to be made from obstinate chronic suppuration or constipation, alternated with diarrhea. Though it must be remembered that chronic diarrhea with mucopurulent discharge may be only a symptom, the indication for operation is urgent when the above symptoms appear in combination, and such patients should be examined thoroughly and repeatedly by palpation of the abdomen and rectum. The diagnosis of the exact site of the lesion can be made in many cases if care is taken. Surgical treatment consists in the removal of the tumor or the relief of the obstruction without attempting to remove it. The mortality is serious, but is being reduced. The palliative operation consists in the formation of an artificial anus or making an anastomosis between the bowel at a point below and above the stricture, to which latter operation may be added the so-called exclusion of the diseased part of the bowel. Curtis thinks, however, that neither of these methods should be attempted in the presence of obstruction. In this event the only method is to form an artificial anus. He is not favorable to the forming of intestinal anastomosis in most cases. It has the disadvantage of the operation being conducted in the immediate vicinity of the diseased tissues, which may necessitate another operation later.

2. **Hydrotherapy in Pneumonia.**—Baruch sums up the effects of hydrotherapy in pneumonia by saying, while it is not a direct nerve agent it fulfils all the therapeutic indications, forestalling or controlling all the depreciating elements of the disease. Only one condition is unaffected, viz., resolution. He has observed the crisis in only about 25 per cent. of the cases. The local course of the disease appears to be changed, resolution proceeds more slowly but more surely, the patient has a normal temperature and pulse, and almost normal respiration for from five to twenty days before all signs of consolidation have disappeared. In the meantime, he permits him to go out in warm weather and endeavors to hasten convalescence by the usual methods, good food, out-door exercise, ventilation, etc. He can explain this delay of resolution only theoretically by presuming that more cases are saved that way, and those who do not have the crisis and rapid resolution would probably add to the great silent majority or pursue a slow convalescence. He uses in adults, as a rule, a wet thoracic compress, instead of a full bath, though in children he employs the full bath with moderate temperature.

3. **Hypnotism in General Practice.**—Martin calls attention to what he deems the value of hypnotism in general practice, and reports cases where he has used it with benefit. Among the conditions in which he recommends it are: Insomnia, nausea of pregnancy, wrenched back, toothache, etc. He thinks that if it were properly used it might have something to do with discouraging the tendency to wander off after the false gods of osteopathy and "Christian science," and other such methods of cure.

4. **Appendicitis.**—Rosewater describes his method of medical treatment of appendicitis in cases where surgery is objected to or seems unnecessary. He thinks enemas with salt water, calomel, purges, ice applications, liquid diet, with salol and caffein to relieve fever and nervous manifestations, are useful. When the inflammation subsides he thinks ammonium iodid in doses of one to three grains every four hours, with copious draughts of hot water, to hasten the removal and destruction of inflammatory exudate is advisable. He gives hot water freely in all cases and in large quantities.

5.—This article appeared elsewhere; see THE JOURNAL of August 11, ¶16, p. 385.

6. **Ectopic Pregnancy.**—Wilcox notes the conditions which may be confused with ectopic pregnancy, and calls attention to the necessity of noting the forgotten early history in some late cases. Cases have actually happened where a woman suffers from vague symptoms which may be referred to other causes, and only the most careful inquiry will bring out the facts necessary for the diagnosis. There is only one safe treatment, and that is operation. He reports two cases which show the comparative ease of recognizing tubal pregnancy before rupture.

8. **Congenital Tuberculosis.**—A case reported by Lyle is that of a child which was born of a consumptive woman who had borne another child during the existence of her disease. Her death occurred at the birth of her last child, which survived several weeks and increased in weight from three and one-half to five pounds, but on post-mortem it was found to have generalized tuberculosis. He thinks it a case of congenital tuberculosis, and the only possible source of the bacteria was from the mother's blood. The intestines and mesenteric glands were free from indication of the disease, which would show that it did not contract it through its diet. The child was ill throughout practically its whole existence.

10. **Metacarpal Fracture.**—Beck publishes a method of holding in position the replaced fragments in metacarpal fracture which he believes is superior to any other device, viz., the use of rubber tubing for splints. The elastic pressure kept up seemed to produce better results than other methods.

12. **Appendicitis—When to Operate.**—According to Carstens we should operate in appendicitis as soon as the diagnosis is made, except: 1, when the environments are bad; 2, when no experienced operator or proper facilities are at hand; 3, in mild, first attacks.

13. **Hysteria.**—This paper, by Mix, treats of the origin of hysteria, which he thinks is probably due to a defective anatomical relationship of the neurones, deformities too fine to be detected by the present methods, which give rise to the disturbance of normal relationships that constitutes hysteria. He remarks on the necessity of looking out for any organic symptoms in the diagnosis, and we must be sure that when hysteria is seen to be present nothing else is present, and that it is not merely a complication or environment. The causes are reviewed. The predisposing ones are: 1, heredity, race, age—it occurring usually between 12 and 20—sex, disease of the sexual organs, faulty education and home treatment. The exciting causes he reduces to psychic and physical trauma, suggestion and possibly toxemias.

17. **Summer Diarrhea in Infancy.**—The gravity of this condition is remarked by Kerley who, says that when the nature of the disease is appreciated the rational treatment consists chiefly in elimination and diet. We must endeavor to remove the bacteria and their products and give nourishment which will not furnish a medium for their growth and development. If the case is seen early, a teaspoonful of castor-oil and a little calomel, in divided doses, should be given. If the case is not seen until late the oil should be omitted and smaller doses of calomel, 1/4 to 1/20 of a grain hourly are indicated. The milk diet, whether natural or artificial, should be stopped at once. The stomach should be washed if there is vomiting, and if there is no vomiting, he instructs the mother to give from three to five ounces of dextrinized barley, either plain or salted, to which is added one or two ounces of chicken, beef or mutton broth. This may be alternated with a teaspoonful or two of beef juice, or one dram of liquid peptonoids added to the barley. The change is useful, as children tire of too monotonous a diet. He has practically discontinued the use of white of egg in water, as many children fail to digest it. His instructions to the mother are as follows: Add two even teaspoonfuls of barley or wheat flour to one pint of water.

This is to be boiled twenty minutes and strained, boiled water being added to make the quantity one pint. When the mixture has cooled to the temperature of 100 F. add one teaspoonful of Cereo, which is a preparation of diastase made for this purpose. If barley is used in this strength it will furnish the child a food containing approximately .64 proteids, .15 fat and .4 soluble carbohydrates. If wheat flour is used, the mixture will contain approximately, .8 proteids, .046 fat, and 2.4 soluble carbohydrates. The milk should be discontinued until the stools are nearly normal and not more than three in twenty-four hours. For the drugs he uses only about four, castor-oil and calomel, already referred to, bismuth subnitrate and opium. The latter should be given with caution and under special indications, and should never be given when the passages are less than four in twenty-four hours. For a child 1 year old 1/100 gr. morphin might be given hypodermically with 1/600 gr. atropin in case of direct infection with prostration and uncontrollable vomiting. Irrigation of the colon is mentioned and is of the greatest service when the stools are infrequent and foul, but has been considerably overdone. As regards prophylaxis, he says the clothing should be of the lightest on very hot days. The infant should be in the open air in the shade, if in the country; if in the city, the coolest room in the house is far better than the dusty streets. Whether in the city or country two or three spongings with water at 60 F. will make the child very much more comfortable. The milk should be reduced in strength from 1/4 to 1/3 on very trying days, adding water to replace the quantity removed. The mother should always wash her hands with soap and hot water before preparing the infant's food or handling any nursing apparatus, and the child with summer diarrhea should not come in contact with very young children, as it is one of the communicable diseases.

18. **Closure of Abdominal Incisions.**—After noting the advantages and disadvantages of interrupted and through-and-through methods of closing abdominal incisions, Richardson says the advantages of both may be united in a very simple combination. This method he has used considerably when from the size of the wound or thickness of the walls immediate security is desired. He first applies the interrupted sutures, which are placed about half an inch apart throughout the extent of the wound. They are then held tense, the opposing areas being brought together in such a manner that the deeper layers are closely approximated, the outer layers apart. The assistant holds these sutures by their long ends in such a way that no intestine or omentum can get caught between the intra-abdominal loops. The muscle and the fascia are still fully exposed. These are now united by interrupted sutures of silk in one or two layers. He contents himself usually with one layer. The layers of peritoneum and fascia are well enough approximated by the long strands of silkworm gut held tense by the assistant. The fascia and the muscle are now united by a single line of interrupted silk sutures. When these are satisfactorily applied, the silkworm gut sutures are one after another tied. In this way no blind spaces are left and the muscle and fascia are united by permanent sutures of silk. He has used this method in exceptional cases, and the more he uses it the better he likes it, and thinks he will come to apply it exclusively to all abdominal wounds.

19. **Consumptives in Los Angeles.**—Dukeman advises consumptives not to go to Los Angeles, as it has no special advantages for this class of cases. The city itself is not in a sanitary condition, and individuals are liable to be infected by former inhabitants of the quarters they occupy. In this paper he gives an elaborate set of rules for the personal use of the consumptive, which are excellent but can not be given in detail here.

20. **Extravasation of Urine.**—The results of extravasation are described by Kramer, who calls attention to the method he employs in all cases of perineal section. In making the operation it is desirable that the field be constantly kept free from blood so that one may know what one is cutting. After the incision is made in the perineum and the urethra opened on the grooved staff, the nozzle of an irrigator, filled with warm salt solution, is inserted into the external extremity of the urethra and a constant stream allowed to flow out of the incision. This has the advantage of keeping the field clear and presenting a constantly visible guide to the urethra and field.

21. **Military Medical Science.**—Brush advocates the instruction in military medical hygiene in our medical colleges. This country is not likely to keep a very large standing army, and the necessity of such training has been demonstrated in our recent experience. There should be a general co-operation of medical schools in this direction.

23, 24, 25. **The Dust Nuisance.**—The first article in this journal gives a thorough description of asphalt pavements and their advantages, by Clifford Richardson, an expert in this particular line of work. In the second article Ernst reviews the different forms of disease germs in their relation to the possibility of transmission in dust, his article being chiefly a synopsis of the paper by Germano in the *Zeitschr. f. Hygiene u. Infektionskrankheiten*, Bds. xxiv and xxv. He thinks that typhoid cholera, and plague bacilli seem to possess least resistance to the process of drying. Next to these come the streptococcus, the pneumococcus, and the diphtheria bacillus, which seemed to be very variable in their resistance, sometimes dying quickly and sometimes lasting for weeks and months. In the third group he places as still more resistant the diplococcus intracellularis and with it the staphylococci of suppuration, and the bacilli of tuberculosis. The fourth and last group includes the spore-producers—which in this way may resist the effects of drying for an indefinite period—such as anthrax, malignant edema, tetanus, etc. Our knowledge of the acute exanthemata is too slight to place them in any of these groups. They certainly do not belong in the first, but it may be doubtful whether they belong in the second or third. The conclusion which he draws is that the danger of this nuisance is greater from the direct irritant itself than from the chance of transmission of any infectious disease. Bowditch calls attention to its effect upon the lungs and alludes to the backwardness of the Boston authorities in the matter.

27. **Recurrent Luxation of the Ulnar Nerve.**—Cotton reports three cases of luxation of the ulnar nerve treated by splints. He concludes that this luxation of itself often gives little or no indication of its existence, it being found only after systematic examination. In traumatic cases, however, there are nerve symptoms, though not necessarily severe ones, and they usually subside gradually and independent of treatment. The operation is for luxation only and cures such symptoms as are really due to this change. It has no special drawbacks as far as it goes, but the author thinks that the nerve symptoms should be considered in deciding between conservative and operative treatment.

28. **The Researches of Apathy and Bethe on the Neuron.**—Schwab's paper takes up the question of the effects of the studies of Apathy and Bethe on the conception of the neuron, and concludes that while the ideal must be somewhat modified, and the endings of the nerve cell can not be accepted as implicitly as before, and the neuron itself may be somewhat questioned as a unit, yet the modifications are not such as to throw aside the theory as a whole. The conception of the neuron as a genetic neuroblastic derivative and limited trophic cell territory will have to be maintained, though the tendency to regard the ganglion cell as the most important and definite part of the nervous system is not perfectly correct. We may still say that the central nervous system is in possession of a definite cell unit.

34. **Some Advances in Minor Surgery.**—The procedures mentioned are: 1. Operation in malignant disease of the testicles. Slaton advises not to cut the cord at all, but after the testicle is thoroughly enucleated, to make traction on the cord, and it will usually give way near the vas deferens. The blood-vessels will be lacerated, but there will be no bleeding. He operated on two cases in this way without hemorrhage, and without ligating the cord the danger of septic infection is thus lessened. 2. Operation for imperforate anus in the new-born. He objects to the advice of Kelsey, Bryant, Ashhurst and others to draw the bowel down and stitch it to the skin. He says it seldom succeeds and he thinks it unnecessary. If the gut is close to the skin it does not need to be stitched, and if high up

stitching will do harm. He would not make an artificial anus in an infant's side at all. He thinks life under such circumstances would not be worth living, and he would rather let the child go to Heaven. 3. Operation for lacerated perineum. He objects to operating immediately after the accident, but operates several days later, using hydrogen peroxid freely during the operation, thus making a surface free from blood-clots and pus. His objection to operating immediately is, first, that the patient is exhausted and suffering, and is in no condition to be disturbed. In the second place, union by first intention is very delicate and can not overcome muscular retraction before the ligatures let go to some extent. They are useful only so long as they keep the parts thoroughly coapted, which requires no more than thirty-six to forty-eight hours. The third reason is that if you operate immediately, some blood-clots form as you close the wound, and if left there they may produce septic infection. The urine and lochial discharges will do no harm if superficial sutures are put in the vaginal rent properly. He ties the knots together and thinks no catheter is better if the patient can pass water without it.

35.—See abstract in The Journal, xxxiv, p. 1563.

39. **Puerperal Infection.**—In his retiring address as president of the Buffalo Academy of Medicine, Mann insists on the importance of avoiding any possible contamination in puerperal cases and points out the difference between simple and septic infection. He thinks that in a large city an accurate diagnosis of these cases is possible. In simple sapremic endometritis a thorough cleansing of the uterine cavity should be undertaken, but in cases of coccal infection, excepting in cases of gonococcus, the condition is critical, and an operation, by opening the tubes in the cul-de-sac of Douglas, draining away the fluid and packing with iodin gauze, is indicated. He thinks in cases of mixed infection, Pryor's plan of thus operating in every case of puerperal infection where curetting is done would be a good one. It may also be extended to opening of recent accumulations of pus in the tubes or broad ligaments, and he has thus operated with eminently satisfactory results. The question of removal of the uterus, when it is the seat of extensive infection, sometimes arises. If it is riddled with abscesses this would seem to be the only means of effecting a cure. The results, however, are not very encouraging. The uterus should be taken out by the vagina, if at all.

40. **Prostatic Hypertrophy.**—Mynter believes in castration for the relief of prostatic hypertrophy, but has little to say for vasectomy. Ligation of the internal iliac arteries is rather a formidable operation, and is dangerous in old and feeble patients. Prostatotomy, including Bottini's operation, is not without its dangers, and is indicated only in cases of hypertrophy of the middle lobe. The most modern operation is prostatectomy, and he modifies this by operating without suprapubic incision, simply pressing the prostate down by force applied over the symphysis. He thinks the Alexander operation modified in this way will be an operation of preference for the future.

41. **Early and Late Operations for Appendicitis.**—After reviewing the methods and their results Smith urges all medical men to join the class of early operators in appendicitis. He says: Do not wait for the interval. When in any possible doubt, the removal of the cause is certainly a safer procedure than medical treatment with surgery held in the background.

46. **Dipsomania and Its Treatment by Suggestion.**—Hypnotism, according to Bramwell, is a valuable agent in the treatment of dipsomania, and he reports cases which he thinks demonstrate this fact. He also quotes from other authorities who hold the same views, but offers the following points for consideration: 1. The patient must be willing to be cured. 2. Susceptibility to hypnosis varies in individuals, but fortunately deep hypnosis is not essential for good therapeutic results. 5. In dipsomania one ought to begin treatment at the beginning of quiescence from an attack, and aim at preventing, or retarding and weakening the next attack. When stimulants are taken continuously, the difficulties are greater, but the patient must be helped to reduce or discontinue their use. 4. The management of the patient during the earlier part of the treatment, before suggestion has taken effect, is important. If it is possible he should not be left alone, but always in the company of some trustworthy person. 5. The operator must be persevering and not easily discouraged. Recovery may occur after several relapses. 6. A distaste for alcohol ought to be suggested as well as the abolition of the craving. The patient must be advised that he can not be a moderate drinker. 7. Even when the craving disappears quickly, the patient ought to be hypnotized regularly for a month, and if he can be seen frequently for six months, so much the better. 8. The object of the treatment is not only to cure the craze, but to strengthen the will. The latter point is important. Some patients forget what they have gone through, and yield again to temptation. He commends Lady Somerset's institutions, where healthy work and religious influences play an important part, as contrasting with some others where these are lacking.

47. **Opium in Infancy.**—Crothers calls attention to the dangers of opium medication in infancy as leading to degeneration in adult life.

52. **Examination of the Sputum.**—The method of examination recommended here by Weidner is that of Guenther, which consists in spreading the sputum thinly on a cover-glass, drying it thoroughly in the air, and fixing it by passing it through a flame three times. Then the cover-glass is floated sputum side down in Ehrlich's solution of either anilin gentian violet or anilin fuchsin. It is then heated over a small flame until the staining fluid begins to boil, and set aside for a minute to prolong the action of the stain. The cover-glass is removed with forceps from the fluid, and without washing, it is placed in a solution composed of three parts of hydrochloric acid and ninety-seven parts absolute alcohol, where it is left for one minute, and rinsed well in distilled water. It should now appear free of all color to the naked eye. The final steps are counter-staining in a weak solution of methylene blue for several minutes, washing in distilled water and drying in the air; if it is to be permanent, passing it through flame. This is done for the purpose of getting rid of all acid which might have a decolorizing effect later on. It is then mounted in xylol balsam and examined with a 1/12 oil-immersion lens, using open condenser and maximum illumination. If the fuchsin is used, the bacteria will be seen as little red rods upon a blue ground, but not everything that stains red is tubercle. The tubercle bacilli are arranged singly or in little bunches, and frequently in a V-shaped arrangement, and are spread all over the cover-glass. They are slightly curved and often have a beaded appearance, which is so characteristic in active bacilli well prepared. The other methods, of Koch-Ehrlich, Ziehl-Neelsen, Gabbet, and others, are also mentioned though he does not employ them. A considerable part of the paper is taken up with a discussion of the distinction between the smegma and tubercle bacilli, and he seems to think the plan of prolonged immersing in alcohol is perhaps as reliable as any.

53.—See abstract in The Journal, xxxiv, p. 1415.

55. **Treatment of Abortion.**—The principles underlying the treatment of abortion and its complications are given by Stehman as follows: 1. The rendering of the vulva, vagina, and uterus aseptic, and so far as possible maintaining them so. 2. The arrest of hemorrhage, either by use of tampons in the cervix or vagina, or by directly emptying the uterus. 3. In inevitable abortion, the ovum, or any part of the product of conception, should be removed as early as possible. 4. Intelligent curettage is invariably indicated wherever a vestige of placental remains or any suspicion of infection is in evidence; a bacteriologic differentiation is necessary both from the standpoint of prognosis and treatment. 5. When circumscribed local infection is a complication, evacuate the pus as early as possible and by the shortest route.

56. **Chloretone.**—Ward has experimented on himself with a number of hypnotics and found chloretone the most convenient and freest from bad effects, and next to this, trional. He believes that chloretone is theoretically the best hypnotic, and thinks it useful in cases of excessive hyperacidity of nervous origin, and especially in those intractable cases of pain in the epigastrium, which comes on at night interrupting sleep and causes the sufferer to take large doses of bicarbonate of soda.

He attributes its effects to its anodyne action on the gastric mucous membrane. For similar reasons he thinks it would be an excellent remedy in acute alcoholism. He would give it in 10-gr. doses dissolved in half an ounce of whisky or brandy, followed later by a raw egg beaten in milk. He has also used it in one case of whooping cough, with marked benefit.

59.—See abstract in THE JOURNAL, xxxiv, p. 1336.

60. **Uric Acid and Epilepsy.**—Putnam and Pfaff have tested the correctness of Krainsky's statement as to the invariable diminution of the excretion of uric acid before epileptic attacks and its increase afterward, using specimens from patients in the Massachusetts State Hospital for Epileptics, at Monson. The method of analysis followed was that of Ludwig-Salkowski—the one now regarded as the best. In all twenty-nine specimens of twenty-four hours' urine were analyzed, coming from two patients, with notes as to the seizures that occurred during the time. They do not find any agreement in their results with Krainsky's statement; the amount was very low in some instances during seizures and high in others.

62.—See abstract in THE JOURNAL, xxxiv, 1336.

64. **Digitalis.**—From an experimental study of digitalis and its derivatives, Arnold and Wood conclude that digitalin and digitoxin each represent the full circulatory powers of digitalis. Digitalin and digitoxin stimulate the cardio-inhibitory mechanism both centrally and peripherally. In larger doses they paralyze the intrinsic cardio-inhibitory apparatus. They all cause a rise of blood-pressure by stimulating the heart and constricting the blood-vessels. 4. Very large doses paralyze the heart-muscle of the mammal, the organ stopping in diastole. Digitalin of Merck is a stable compound, one gram of it being equal to about 70 c.c. of tincture of digitalis. Digitoxin is not to be recommended for human medication, on account of its irritant action, which makes it liable to upset the stomach when given by the mouth, or to cause abscesses when given hypodermically, and on acount of its insolubility, which renders it slowly absorbed and irregularly eliminated, having a marked tendency to cumulative action.

71.—Ibid., p. 1334.

72.—Ibid.

73. **Ossification of Choroid.**—The case reported by Randolph is interesting from a medicolegal point of view. The man was drowned in Niagara River and his body was found nine months later. The insurance company demanded an examination; and identification of the body was determined by its showing ossification of the choroid in one eye that had been known to be blind.

75. **Vision and Seasickness.**—Sumner believes that seasickness is an ocular phenomenon, and in evidence of this presents the case of a house that was carried away by a flood and deposited in a very abnormal position. Though perfectly stationary, it made persons who entered it seasick. The disturbed relations affected the field of vision in such a way as to produce the reflex symptoms of *mal de mer.* He believes the disturbance is really a psychic one, caused by conflicting mental impressions which produce systemic disturbances.

76. **Tobacco Amblyopia.**—The subject of tobacco amblyopia is discussed by Polkinhorn, who does not agree with the statements made by most observers that the vision seldom if ever falls below 20/200. He thinks in one-half the cases he has seen the reduction was below this figure. Most of his cases were pipe smokers, and nearly all made use of a short, clay pipe, called a "nose scorcher" on account of its size, the stem being only about one and one-half or two inches in length. More nicotine is absorbed in using such a pipe than when using a pipe with a longer stem. In one case, the patient was a female who had every symptom of the disease, but did not smoke herself. She spent most of her time in the room with her husband, who was a paralytic and a constant smoker. Whether this was a true case of amblyopia, caused by inhalation of tobacco fumes when the bodily health was below par, he is not able to positively state. The part played by alcohol in this disease is, he thinks, over-estimated; tobacco is responsible, in his opinion. The prognosis where there is no actual scotoma or contraction of the visual field and the patient is willing to obey directions is, he thinks, good.

77.—This article has appeared elsewhere; see also THE JOURNAL of July 28, lxi, p. 258.

82. **Mountain Fever.**—Stuver believes that mountain fever is simply a form of typhoid, modified a little, perhaps, by the conditions of open air, etc. He uses rectal injections of cold normal salt solution as a substitute for the cold bath, and thinks them more available and equally valuable. The treatment in other respects is also described.

83. **Psychic Shock.**—The participation of this element in the production of various disorders, and especially its relation to surgical shock or complication is here emphasized by Roberts. He thinks the physicians should pay more attention to the mental condition of their patients, and the existence of excitable mental equilibrium should at times turn the scale against operation altogether. The use of suggestive therapeutics is advised in some of these cases.

84. **Altitude and Insanity.**—The effects of climate on mental diseases are, according to Solier, very much neglected by authors of works on diseases of the mind. The only exception he makes to this general rule is Dr. Kellogg's recent work. It, however, makes no allusion to the effect of altitude on insanity, excepting that the author recommends a low, rather than a high altitude when the cerebrospinal centers are damaged by the occurrence of organic lesions. The authors who have written especially on this subject in medical journals are Eskridge, of Denver; Solly, of Colorado Springs, and Work, of Pueblo. They do not find that high altitude is especially damaging to the neurasthenic in most cases. Solly analyzes the conditions at the Wyoming State Asylum at Evanston, and comes to the conclusion that altitude is not an appreciable factor in the production of insanity.

85.—See also abstract in THE JOURNAL, xxxiv, p. 233.

94. **Brain Tumors.**—Seventeen cases are here analyzed, and the leading symptoms in the order of their frequency are given by Diller, as follows: Headache, vomiting, optic neuritis, eye palsies, ataxia, mental symptoms, hemiplegia, general convulsions, altered knee-jerks, and vertigo. The author thinks the prognosis is always serious, and in only one of eight cases that were operated on of the seventeen, was there any relief. Surgical interference is not very hopeful, though it is not to be discarded absolutely. He believes in the medical treatment by the use of potassium iodid in large doses, 300 to 400 grains daily if possible, and where this fails, an operation may be undertaken. If localization of the tumor is impossible, or if it is inaccessible, perhaps simple trephining may do good.

104. **Cannabis Indica.**—This is one of the older drugs that has suffered somewhat from neglect, but, as Lewis thinks, undeservedly. In small doses it is first stimulating, later sedative. He describes the symptoms of cannabis intoxication, and believes that there is no fatal dose by the mouth in the human subject. He thinks there is a limit to the absorption of the drug when administered by the mouth, since he finds as much effect from 10 grs. as from a larger dose. As far as he knows there are no drugs that counteract its effects satisfactorily; hyoscin hydrobromate comes the nearest to it, and during the somnolent stage, when the respiration and heart become embarrassed, hypodermic injections of strychnin and nitroglycerin are effective, as is also a rectal enema of strong coffee and brandy—two ounces of each. The uses of the drug are manifold, but are almost exclusively limited to diseases due to nervous derangement. In migraine, hemicrania, neuralgias, and headache due to eye-strain, it may be used with marked success, and it is one of the best of anodynes in multiple neuritis. It is one of the most valuable and satisfactory drugs in the neuroses accompanying pregnancy, and dysmenorrhea is one of the principal indications for its use. It is unequaled

to quiet the neuroses, pregnancy and the menopause. It is a valuable adjunct to quinin, and he believes from his own observation that it has a powerful action on muscular contraction, particularly of the uterus, and combined with ergot is a valuable adjunct. It is useful in profuse menstruation, decreasing the flow without completely arresting it. He has not found it of much value as an aphrodisiac, though it may be somewhat effective in some cases of impotence. He has seen evident improvement in several cases of diabetes mellitus, and it is very useful in relieving intolerable itching and burning in all neuroses of the skin. The preparation he uses is assayed solid extract in doses of one-fourth of one grain. He uses one-fourth grain tablets, and repeats the dose every one, two, or three hours, as needed.

106. **Ergot.**—The uses of ergot are related by Jackson, who finds it valuable in fibroids, uterine hemorrhage, Bright's disease, diabetes, brain congestion, hemoptysis, and the hemorrhage of typhoid fever and dysentery.

108. **The Nuclear Structure of Bacterial Cells.**—In this article King reviews the literature of the nuclear structure in bacteria and concludes with the suggestion that two definite substances are to be recognized in the bacterial cell: a cytoplasmic substance and a nuclear substance; that the nuclear substance is simpler in form than in the less degenerated plant forms, but that it has a definite structure which is found in principle in all bacterial cells, and which plays an important part in cell division.

118. **Appendicitis.**—French objects to the use of purgatives in appendicitis, as he thinks they increase the peristaltic movement and contribute to the invasion of infection. Operative treatment is unnecessary only in chronic lesions in which the peritoneal layer is unaffected, and no adhesions exist. In such cases it is not justifiable. When abscess is present but the appendix is not readily accessible, there should be no attempt to find or remove it, as this will increase the danger. He lays down the following rules as to the time of operation: 1. In fulminating appendicitis, when the perforation is large, when invasion is rapid, symptoms are severe, and the blood-count shows signs of infection, operate early. 2. After recovery without operation from a general attack, operation is justifiable. 3. After suffering several mild attacks. 4. Operate after the third or fourth day in cases where the blood-count, pain, vomiting and high pulse-rate indicate the spread of the infection or an increase in its virulence. He thinks the process we call inflammation is conservative, and if we knew the dividing line between repair and destruction we could state the exact minute when operation is necessary.

120.—This article has appeared elsewhere. See The Journal of August 4, ¶75, p. 319.

126. **Digestive Enzymes vs. Bacteria.**—The practical point of Randall's paper is the inconstancy and instability of digestive enzymes as compared with the constancy and stability of living bacteria. He believes that we have in formaldehyde and isoethylin valuable food preservatives which have a wide sphere of usefulness.

130. **Rheumatism and Life Insurance.**—Looking at rheumatism from the insurance standpoint Young concludes that: If the disease has occurred in the ancestry and not in the applicant it need not be considered, for heredity can be traced in only about 30 per cent. of the cases, and it does not follow that it exists. If the applicant himself, however, has had an attack the case is different. As a rule, the earlier the primary attack occurs, the greater is the likelihood of repeated attacks; the greater the severity and danger of cardiac complications; the later the age the less the danger. Occupations calling for great muscular activity with fatigue, especially where the applicant is exposed to sudden chilling, produce more than one-half the cases. If he persists in such occupation, the risk is increased. Conditions of living which lower the tone of the nervous system, or serve to enfeeble the muscular system, increase the chances of recurrence. The same is true of diseases that lower the bodily resistance. A combination of two or more of these elements makes the case so much the worse. These influences upon the desirability of risk are to be considered independently of those arising from residual effects of rheumatism, which are far more important, but are not here considered.

132. **Female Risks in Life Insurance.**—The experience of the Union Central Life Insurance Company with female risks is given, showing a strikingly unfavorable percentage, although the later mortality has been more favorable than the earlier, partly on account of advance in the science of obstetrics, and a rule postponing pregnant cases and those recently married. Consumption and cancer, however, are still the most unfavorable factors in the increased death-rate. Davis thinks the cause of this may probably be found in the careless examination of women, who are rarely thoroughly examined by medical examiners. Many women do not know when they are in ill health, and thus mislead, though they do not intend to answer falsely. In males it is different. In most cases the man breaks down and when he is ill is very sick. He is not schooled in suffering like the woman.

134. **Submucous Ligature for Rectal Hemorrhoids and Prolapse.**—The operation described by Ricketts consists in passing a needle subcutaneously around the hemorrhoidal varices. Its advantages are stated as follows: 1. The impossibility of secondary hemorrhage. 2. There is no tissue destroyed or sacrificed. 3. The loss of time is but little, if any, greater than when they are removed by the clamp and cautery. 4. Thus far there has been no infection. 5. There has been no fistula, abscess, or fissure resulting therefrom. 6. The pain is no greater, and, perhaps, less, than in other methods of ligaturing. 7. There is absolutely no stenosis. The operation is described and illustrated. He passes the needle part way around, then inserts it at the point of exit to come out again at the original point of entrance. In cases of but one or two hemorrhoids one ligation of this character is sufficient, but when they are multiple, as many as are required may be used. The operation for prolapsed rectum is similar.

FOREIGN.

The Lancet, July 28.

Chronic Pancreatitis. A. W. Mayo Robson.—Pancreatitis is a result of bacterial infection, as has been proved both by clinical observation and experiments on animals. Mayo Robson considers it under three heads: 1, acute; 2, subacute, and 3, chronic, which should not interfere with the pathogenesis or classification of the acute form into hemorrhagic, suppurative and gangrenous. The symptoms are very variable and differ in special forms, with no pathognomonic signs, and in each a study of the history, onset, and symptoms is necessary. Acute pancreatitis usually begins with sudden pain in the superior abdominal region, with faintness or collapse, followed by vomiting and almost constantly accompanied by constipation, so that it is frequently mistaken for obstruction. The obstruction here, however, is not absolute. The pain is soon followed by distention in the superior abdominal region, which may become general. The pulse, which is rapid and small, is a better guide than the temperature, which may be sub-normal or normal. Delirium comes on later, and death usually supervenes in from two to five days from collapse. Subacute pancreatitis may also commence with acute pain. Tenderness over the pancreas is marked, and the swollen gland may sometimes be felt. Collapse is not so pronounced, pulse less rapid, constipation gives way to diarrhea, temperature may reach to 104 or 105 F., and yet be normal in the morning; rigors may occur. Loss of flesh and feebleness with albuminuria is pretty constant. The patient gradually succumbs. An abscess may become prominent by its tumor, and burst either in the bowel or stomach or point externally. Chronic pancreatitis, at first hypertrophic, but later cirrhotic, is usually considered rare, but he thinks it much more frequent than either of the other forms. He has operated on a large number of cases of jaundice, apparently depending upon obstruction to the common bile-duct, which led him to this belief. The onset may be gradual, the pain may be severe at times and resemble that of bilious colic, but the tender spot is usually an inch above the umbilicus in the middle line, and not over the gall-bladder, as in cholelithiasis. Jaundice tends to deepen with each attack, until it becomes continuous. Loss of flesh and strength are characteristic. Albuminuria is common, diarrhea is often present. The symptoms of fever are variable, as is likewise the pulse. In the later stages, hemorrhage from the nose and bowel and vomiting of blood, show blood degeneration, and death ensues from increasing weakness. The diagnosis is to be made from gall-stones in the common duct, cancer of the pancreas, the liver and bile-ducts, and chronic catarrh of the bile-ducts. From gall-stones the diagnosis is of no great importance, since the conditions are often associated and the treatment is the same; still, it may be made by the history, as a rule. In cancer of the head of the pancreas the onset is usually gradual and painless, and the disease ordinarily occurs later in life, after the age of 40. It is preceded by general failure in health. Jaundice when it occurs is absolute and unvarying, and there is nearly always a tumor of the gall-bladder without tenderness. The liver is enlarged, and, in some cases, a hard nodular tumor may be found on the under side of the distended gall-bladder. Extremely rapid loss of weight and strength with increasing anemia, but without ague-like seizures, is very characteristic. It is common for this to be absent, with still feeble pulse and later ascites of the lower limbs. Cancer of the bile-duct is rare, and when present may resemble and is usually associated with gall-stones. With cancer of the liver, irregular enlargement, nodules following rapid loss of health, less constant jaundice and absence of fever usually point to its existence. In many cases the diagnosis can be made only by exploratory operation. The disease may last for months, or even years, and it is probable that many cases called chronic catarrh of the bile-duct may be of this character. Glycosuria, increasing weakness and hemorrhage make the outlook bad. Under surgical treatment the prognosis is very favorable, as sixteen out of his seventeen cases have recovered. In acute disease there is seldom much chance for treatment; the symptoms are too indefinite, and the course too rapid. The subacute form is more amenable to treatment, but has usually been attacked surgically only when an abscess has formed. There is no reason why surgery might not be done earlier. Morphin may be necessary for the pain. Calomel as an intestinal antiseptic, and bismuth and salol, and small doses of opium when diarrhea occurs, may be of benefit. The strength must be maintained by careful feeding and judicious use of stimulants. Evacuation of pus is requisite, and other collections must be looked out for. In the chronic form, surgery is indicated, and for attacking the head of the pancreas or pancreatic duct the vertical incision should be made through the right rectus, and not in the middle line. In all cases of deep jaundice he prescribes calcium chlorid in 20-gr. doses thrice daily for twenty-four and forty-eight hours before operation, and gives it in the form of an enema twenty-four hours afterward in 60-gr. doses three times a day. He says that if the papilla is incised it does not require suturing, and in cases where he has explored the ducts by the duodenal route there has been no hemorrhage. The anterior duodenal opening requires closing by mucous and serous sutures. This is best done by a stab-wound at the most dependent part. A number of cases are reported which illustrate the course of this disease under treatment. He remarks that the contrast between the results of malignant disease, of pancreatitis, and the ordinary interstitial chronic pancreatitis is most striking. This article appears to be practically the same as that presented by the author at the late International Medical Congress. (See cable report in The Journal, August 11, p. 375.)

British Medical Journal, July 28.

Physiologic Action of Senecio Jacobea. J. L. Bunch.—The author has studied the physiologic action of Senecio jacobea, the investigation having been undertaken by the Therapeutic Committee of the British Medical Association. His article is illustrated by tracings showing the blood-pressure and the effect upon the heart. The following are his conclusions: 1. Injection of an alcoholic extract of the entire plant of Senecio jacobea into the circulation of a dog in small doses causes a rise of general blood-pressure, with constriction of peripheral vessels and of vessels of the intestinal area. This effect is accompanied by a diminution in the magnitude of the contractions both of the auricle and of the ventricle. 2. Large doses—.8 to 1 gram for a dog of 7 kilos—of the drug cause a fall of general blood-pressure, with dilatation of the intestinal vessels and inhibition of the contractions of the intestinal coat. 3. After several injections of small doses, or after one large dose of the alcoholic extract, further injections produce a fall of blood-pressure, with slowing of the heart, and this effect is repeated unless a considerable interval is allowed to elapse before any further injection of the drug, which then again causes some rise of general blood-pressure. 4. The entire plant, therefore, contains two substances with distinct physiologic actions, but he has not up to the present been successful in locating them. 5. Watery extracts of the residue obtained by evaporating the alcoholic solution produce a fall of blood-pressure and cardiac inhibition, due to the action of the drug on the nerve terminations in the heart, and not to direct action on the muscular fibers of that organ. 6. The substance which causes a rise of blood-pressure is not contained in such watery extracts, or if present, is only in small quantities.

Oral Sepsis as a Cause of Disease. William Hunter.—The writer, who has been rather prominent in tracing disease as a result of dental decay here takes up the subject again and claims that he finds for every case of gastric or other affection traceable to pyorrhea aveolaris there are a hundred equally well-marked associated with dental or oral conditions of sepsis. The important point is that they are all septic in their nature, and are produced by pus organisms. He thinks there are no such virulent necroses as those grown in connection with necrosing bone, and that is the character of those connected with carious teeth. No physician or surgeon, he says, would allow a patient with a foul septic ulcer on his forearm to apply his lips to the ulcer to clean it, yet this is pathologically what happens in patients with carious teeth or stomatitis. Moreover the swallowing is constant, and for years unheeded by the patient or physician. As instances of these conditions he reports the case of a woman who suffered from inexplicable salivation and subsequent intestinal trouble so severe in character as to confine her to the bed, and another who had gastritis and various rashes, besides nervous attacks It is probably impossible to prevent occasional access of typhoid, tubercle, and other infectious germs. They need not, however, keep us from taking the most exhaustive precautions for saving our house from typhoid contamination or preventing access of tubercle bacilli. Therefore, he maintains that the mouth, which is so accessible to local treatment, should not be made into a perfect hotbed for their development and propagation. By oral antisepsis he means, not merely washing the mouth with mild astringent and antiseptic mouth washes, but the direct application to the diseased tooth or inflamed gum of carbolic acid—1 in 20—daily as long as the patient will persist in keeping the fang, or, better, the removal of all diseased useless stumps, the most scrupulous boiling of every tooth-plate worn, and avoidance on the part of the dentist of too much complicated surgery, such as bridge work, which can not be kept aseptic.

Nature and Action of Snake Venom. Robert Henry Elliott.—The author has investigated the effects on the mongoose of the cobra venom and finds that much larger doses can be borne by this animal than would naturally be supposed. These animals in their normal, active, healthy existence could have borne more, he believes, than those that were the subject of his experiments, as these last had lost more or less of their immunity while in captivity. He notices the fact that the mongoose loses considerable of this immunity in Guadeloupe, where it is not exposed to the snake venom, as it is in its native residence. He finds, for instance, the proportion that would kill a rabbit, dog, and a mongoose, are, roughly, rabbit, 1; dog, 2, and mongoose about 10 to 25. He mentions amongst other things the fact that the bristly hair of the mongoose is protective, as the mongoose terrifies the snake by appearing larger than its real size, and by its agility to escape most of the attacks. He doubts if the mongoose alone is peculiar in this matter, for even dogs or cats have been known to be successful in killing poisonous snakes. Snakes differ in their characters; the cobra is an animal that is subject to hypnotism, a fact known and used by the Indian snake-charmers, who are by no means immune to its bite. If they seem [illegible] the venom someti [illegible] it or [illegible] rms it ha [illegible] effect and is not [illegible] ny [illegible] reaso [illegible] sell viper—Daboia—is a different-tempered animal, and is never used by snake-charmers. It is not so safe to handle as the cobra. He sums up his conclusion in regard to snake-charmers in the following words: 1. The snakemen of South India are certainly ignorant of any method of producing in themselves a highly-developed condition of immunity. 2. Some few of them appear to practice the swallowing of venom, or the inunction of venom into their limbs, but it is doubtful if they do so with any well-defined object. It is possible that they thus obtain some degree of immunization. 3. They confine themselves almost exclusively to the cobra, and escape harm by their intimate knowledge of the methods of handling the snake.

Bulletin de l'Academie de Medecine (Paris), July 10 and 17.

Treatment of Aneurysms with Gelatin. Lancereaux.—In the patient first treated with injections of gelatin, the skin had commenced to yield to the pressure of an enormous and rapidly increasing aneurysm of the aorta, which had perforated the sternocostal wall. The injections of gelatin were made as a last resort. Improvement was evident within twenty-four hours, and in a short time the patient was restored to comparative health, able to climb stairs, and he even fell from an omnibus without disaster. Death occurred more than a year later, after an intercurrent attack of la grippe, and the autopsy confirmed the obliteration of the aneurysmal sac, and of a second smaller sac for which the patient had taken a second course of injections. Lancereaux adds reports of nine new cases, in all of which the patients were very much benefited by the injections. He restricts the treatment to sac aneurysms, affirming that it is useless in simple spindle-shaped enlargement of the artery. An indispensable condition for success is the slowing of the arterial current. Twenty-five injections at least are required in most cases. About 5 gm. of gelatin are dissolved in 200 c.c. of artificial serum, for one injection; it is repeated in a week, and, properly administered, there is neither general nor local reaction.

Diabetes from Tumor in Fourth Ventricle. Marinesco.—The complete observation of a gliosarcoma in the floor of the fourth ventricle, reported in this communication, shows that a lesion at this point first affected the centers for the secretion of urine, inducing a polyuria amounting to eight or nine liters a day, without glycosuria, and later, when the lesion had invaded the centers which preside over the sugar formation, the diabetes was transformed from insipidus into mellitus. The case also establishes that the center of respiration is not at the calamus scriptorius, but lower down, coinciding with Marinesco's experimental research. The hemorrhages into the medulla produced each a bulbar ictus, but did not arrest respiration. Death did not occur until hemorrhage had invaded the aqueduct of Sylvius and third ventricle. The lesion encroached on the upper part of the nucleus of the hypoglossal nerve, the dorsal nucleus of the pneumogastric and the posterior longitudinal fasciculus.

Gazette Medicale Belge (Liege), July 26.

Physicians and Sickness Insurance Societies. Cuylits.—This address was one of the features at the Congress of Professional Medicine. The speaker is one of the foremost leaders in the "Battle of the Clubs," which has been waged so bravely in Belgium. He stated that in 1895 there were 756 "mutualities" in that country—societies organized to insure against sickness, accident, infirmity, or old age. The number has progressively increased, until now there are over 3000 with a membership of considerably more than 350,000. Estimating five souls to a family, this makes 1,750,000 individuals, and adding the numerous other organizations which are not legally incorporated, and co-operative associations, it is no exaggeration to assert that 3,000,000, or very nearly half the population of Belgium, is entitled in some way or another to medical attendance at reduced rates, practically gratuitous. The principle of sickness insurance is permeating more and more every day all classes of society. He referred to our American lodges, etc., as an ideal in respect to their method of medical attendance; each disabled policy-holder receiving his indemnity each week, out of which he pays his own doctor's bills, selecting the physician he prefers. "Europe has much to learn from America in this respect." Meantime he proclaimed the principles which he hoped the Congress would unanimously endorse and promulgate: 1. Every true "mutuality" should be entitled to a minimum medical tariff, which would be incompatible with our professional dignity under any other circumstances. 2. The "mutuality" can have the benefit of these terms only on condition that it will not admit well-to-do per-persons to membership. 3. The tariff should be established by agreement between the "mutuality" and the professional medical association, and may differ and conform to the resources of the "mutuality" and the local conditions at various places. 4. All the local physicians should be notified of the tariff when adopted, leaving each one free to accept it or not. 5. The system of hiring a physician on a salary can not be tolerated, and the choice of the physician should be left to the patient. 6. A general medical superintendent should be one of the officers of the society. He should visit the patients occasionally to ascertain that the medical arrangements are working properly—in the interests of the patient as well as of the association; once a week is sufficient. Adoption of these principles would establish "lodge practice" on an equitable basis, with no further cause for wrangling.

Grece Medicale (Syra) July.

Epilepsy Cured by La Grippe. G. L. Coveos.—A 10-year-old lad passed through an extremely severe attack of la grippe. When he recovered there were no further manifestations of the epilepsy, with which he had been affected since his third year. The seizures had recurred every second day and resulted in complete idiocy by the time he was 8. The attacks had always been confined to the face, but the symptoms were typical in other respects. After recovery from la grippe his intelligence returned, all trace of the epilepsy vanished, and in a year the boy had surpassed his brother in school. The epilepsy must have been symptomatic, not idiopathic.

Presse Medicale (Paris), July 18 and 21.

Unilocular Cysts in Pancreas. L. Bérard.—A large unilocular cyst containing two liters of fluid, in a woman 51 years of age, was differentiated as a tumor of the pancreas by its high location, and its synchronous displacement with the pulse of the abdominal aorta without true expansion of the fluid contents, which demonstrated its immediate contact with the arterial trunk. Another point was its comparatively easy mobilization laterally, while it was impossible to move it up or down or forward and back, suggesting a deep-seated stem. It was also independent of the liver, whose lower margin slipped back and forth on it and did not drag it down except in forced inspiration. The stomach was also independent, and during insufflation masked the area of dulness over the cyst. Bilton Pollard has recently reported three successful cases of this nature treated by incision and drainage, and this observation adds a fourth. Oser's statistics in 1898, of 140 cases of pancreatic cysts, demonstrated conclusively the benefits of this method of procedure. Recovery was complete in 80 per cent. within three months. Location between the stomach and liver—as in this case—is the least favorable for a radical operation, on account of adhesions, but median laparotomy should be the first step in all intervention on account of a pancreatic cyst.

July 21.

New Conception of Myelogenic Leukemia. H. Dominici.—The autopsies in two cases of myelogenic leukemia and much experimental research have demonstrated that the essence of the reactionary process induced by some unknown cause and known by this name, is a hypergenesis and generalization of the myeloid tissue. The manifestations are: 1, the multiplication of this tissue in the zones in which it exists naturally active, as the bone-marrow of the sternum, ribs and spine; 2, the revivifying of this same tissue at the points where it persists in a rudimentary or latent condition after having passed through a phase of activity at some period in the intrauterine or extrauterine life, i. e., in the spleen, liver, ganglia or diaphyses of the long bones; 3, the multiplication in the vessels of elements of the myelogenic series—issuing from these various foci—thus forming remote colonies. Myelogenic leukemia is not a disease of an organ, the bone-marrow, disseminating its elements throughout the rest of the organism by metastasis, colonizing at certain points as myelomata. On the contrary, it is essentially a disease of a tissue, the myeloid tissue in particular, which enters upon a phase of excessive activity in its normal locations and also at points where it persists latent or rudimentary. Among the facts on which this conception is founded are: 1, the possibility of inducing diffuse myeloid transformation of the spleen, experimentally and independently of any metastatic process; 2, the autochthonous origin of the newly-formed intrasplenic tissue; 3, the identity of the structure of this myeloid tissue in the spleen of the animals in the experiments and in the spleen of persons affected with myelogenic leukemia; 4, the modality of histogenesis, peculiar to myeloid tissue, which is manifested in the different organs, and which, although it may retrogress, is capable of resuming its activity at any time.

Semaine Medicale (Paris), July 10 and 25.

Raw Meat an Antitoxin. C. RICHET.—As already announced in THE JOURNAL, Richet claims that raw meat checks the development of experimental tuberculosis and cures it. The amount necessary and sufficient is 12 gm. per kilogram of body weight. The active principle of the meat in this respect is the muscle plasm. The effect of treatment can not be attributed to superalimentation, as experiments on tuberculized dogs have demonstrated that the raw meat acts as a medicine, not as a food. The effect is not due to its digestibility nor to the nitrogen it contains, as cooked meat is as digestible and as rich in nitrogen but has none of the specific antitoxic power of the raw. Raw meat acts by its enzymes, its ferments, its diastases, which possess the beneficent property of opposing the tuberculous infection. Tests on man have indicated the probability that raw meat in the treatment of human tuberculosis should be prescribed in large doses, 600 to 750 gm. at least, every day, or if the muscle plasm is used alone it should be from 1000 to 1500 gm. as the minimum. The use of raw meat should not be reserved for tuberculous patients with digestive troubles, but given to all, as it is a remedy—a heroic remedy—against the tuberculosis itself. Consequently it should be administered from the start. In short, raw meat, or to be more accurate raw muscle plasm, is not only a food, but it is also and chiefly, an antitoxic agent.

July 25.

Diagnosis of Renal Insufficiency. C. ACHARD.—This comprehensive and scholarly article was one of the addresses presented at the International Congress of Medicine. It states that the usual clinical and diagnostic data are better adapted to determine the existence and nature of the lesions in the kidneys than to establish disturbances in function. The anatomic lesion and the physiologic disturbance are, however, not always proportionate, and on the other hand, the functions of the kidneys may be seriously compromised while the symptoms are rudimentary and the general health maintains a deceptive appearance of normal conditions, while a more or less precarious compensation masks the real danger threatening the organism. Besides estimating the volume and specific gravity of the urine, the casts and albumin, it is necessary to determine the state of the function. This can be accomplished by comparing the urine and blood, with tests both chemical, physical—cryoscopy—and physiologic—toxicity—or by study of the elimination with a foreign substance. The latter and cryoscopy are the only two of these methods currently practicable. Comparison of the freezing-point of the blood and of the urine, combined with certain chemical reactions of the latter, furnishes very instructive information in respect to the condition of the renal circulation and the general nutritional processes, but the calculations required to make these deductions are possibly a little too complicated for daily practice. The test of function by induced elimination, which is generally done with methylene blue, is a simple and easy method of obtaining an oversight of the time required and the proportions in which the kidney succeeds in freeing the organism of the substances for which it serves as the emunctory. Cryoscopy and test-elimination can be advantageously combined, and together, form a means of pathogenic research which is liable to throw light on certain still obscure and theoretic points. It is also of great practical utility, confirming the indications derived from clinical examination at the bedside, and sometimes revealing hitherto unsuspected or erroneously diagnosed disturbances in the renal function, especially in certain cases of interstitial nephritis developing insidiously. Study of the glycosuria induced by phlorizin is useful to supplement the elimination test with methylene blue. Achard's method consists in a subcutaneous injection of 5 mg. of phlorizin. The glycosuria is "regular" when sugar appears during the first hour after this injection and disappears by the end of the third or fourth hour, the amount ranging from .5 to 2.5 gm. In pathologic conditions the glycosuria may be exaggerated in duration or quantity, but in most renal affections it is insufficient or entirely absent. This hypoglycosuria or anaglycosuria may be observed in connection with impermeability for methylene blue, in patients with interstitial nephritis, before any albuminuria appears. These phenomena may also occur transiently in the course of an acute infectious disease. In some cases the results of the two methods of exploration do not agree, as in an acute or subacute nephritis which allows free passage to the methylene blue with no evidence of glycosuria after the phlorizin test. The latter is manifestly a more complex phenomenon than the simple elimination of a coloring matter, but it is interesting to note that in certain unmistakable and profound lesions of the kidneys, while the elimination of the methylene blue and of other substances in the blood may be proceeding apparently normally, the injection of phlorizin affords a means of verifying that the functional activity of the renal elements is defective at least in certain directions. These facts suggest the possibility of still other functional disturbances, affecting unknown biologic activities of the renal parenchyma, which may possibly have a share in the pathogenesis of uremia.

Cocainization of Spinal Cord in Obstetrics.—The practicability of substituting intraspinal cocainization for general anesthesia in obstetric cases has been established by Doléris at Paris and Bumm at Basle, who each simultaneously report five or six cases in which it was done with the most satisfactory results. One to 2 cgm. of cocain were injected into the subarachnoid space, and in five to ten minutes there was complete analgesia of the lower part of the body to the costal arch, but no interference with voluntary movements. The uterus continued to contract with the same energy and frequency as before, but painlessly. The pain from pressure of the fetal head on the soft parts was also abolished, and the patients ceased to feel the desire to "bear down." Delivery and the later course of the puerperium was normal in every respect and the fetus did not show any indications that it had been affected by the cocain in any way. A laceration of the vagina occurred in one case, which was immediately sutured and no pain was felt by the patient. The analgesia lasted from an hour and a half to two hours. In Doléris' experience the uterine contractions seemed to become more frequent. more vigorous and to last longer than previous to the cocainization, and during the intervals the uterus remained in a state of semitension for a variable period. This latter fact suggests that this method of anesthesia is contraindicated in cases in which podalic version is liable to be required. The amount of blood lost seemed less than usual. Five of Bumm's patients were primiparæ.

Berliner Klinische Wochenschrift, June 16.

Phlorizin Test of Renal Function. L. CASPFR.—The importance of this test of the function of the kidneys is evident from Achard's article above. The introduction of a small amount of phlorizin into the body stimulates the kidneys to a functional activity, the products of which—the glycosuria—can be quantitatively determined with ease. By catheterizing each kidney separately Casper has found that the post-phlorizin glycosuria in each organ can be studied alone. With sound kidneys the glycosuria is the same in each, and lasts during the same period, but a diseased kidney excretes much less sugar than its sister organ, or, in case of an extensive lesion, none at all. The glycosuria may vary in amount and duration in each kidney, with bilateral renal disease, or be absent in both organs. With rare exceptions, the elimination of sugar and of urea and the molecular concentration parallel each other. The writer considers the phlorizin test the best of these three methods of investigation and hails it as a distinct advance in the diagnosis of renal functional activity.

Centralbatt f. Chirurgie (Leipsic), July 21.

Sterilization of Hands with Varnish. J. LEVAL.—Two years ago the idea occurred to Levai that a varnish might effectually protect the surgeon's hands and render them sterile. He has since been conducting extensive research in this line and believes that he has solved the problem of hand sterilization with a varnish which fulfils all the desired conditions; the most trying tests for a whole year have only confirmed its value. Two parts by weight of copal and four of Venetian turpentin are warmed with gentle heat and constantly stirred until thoroughly blended, while the water and volatile oil are expelled. When the mass is cold it is dissolved in 100 parts ether sulph.; 100 parts collodium simplex are then added, and later 8 parts of acetone, and the varnish is ready for use. It is removed from the hands in a few seconds with a cloth dipped in 2 parts ether and 1 of alcohol. Chirol and other varnishes have recently been recommended for this purpose, as mentioned in The Journal of July 7 and 28, but Levai states that they contain substances which his tests compelled him to reject on acount of certain properties. Chirol has been patented by the manufacturers, and Levai observes that he intends to maintain all his legal rights to his process.

Deutsche Medicinische Wochenschrift (Berlin), July 19.

Protection Against Hydrophobia. Marx.—It seems evident from the research reported in this article that the rabies virus becomes attenuated during its passage through small animals. Consequently in the Pasteur method of treating hydrophobia the rabies microbes are less resistant and are killed in the human organism before they can reach the central nervous system. As the microbes die they break up and the contents escape, inducing an irritation which stimulates the production of an antitoxin in the organism. Tests on monkeys have confirmed this attenuation of the virus, which had nevertheless lost none of its immunizing power. The harmlessness of the Pasteur injections is thus experimentally explained.

Improved Technique of Antiplague Vaccination. C. Terni.—The essential feature of Terni's modification of Haffkine's method of antiplague vaccination is the use of a small amount of an extremely virulent culture of the plague bacillus —as described in The Journal, July 14, p. 125—with which guinea-pigs and rabbits are immunized. Among its advantages are the combination of a protective with the vaccinating substance, and the fact that active immunity is obtained with it in man in four to five days after inoculation with the lymph, while ten to twelve days are required with Haffkine's method. The immunity attained with a single vaccination lasts for two months, and it is not followed by high fever nor the painful local infiltration always noted with the Haffkine lymph. The entire process of obtaining the lymph and vaccinating requires much less time with a far smaller amount—1 to 2.5 c.c.—. accomplishes the maximum effect.

Muenchener Medicinische Wochenschrift, July 17.

Early Diagnosis of Tabes. W. Erb.—Much of the present confusion in neurology would be avoided if tabes were more generally recognized in its incipient or latent stages. Erb describes several groups of cases differing widely from the classic picture, but all had been preceded by manifestations of secondary syphilis from four to twenty-three years before, and the later course of the disease confirmed its tabetic nature. In the first group the objective signs were very slight; the tendon reflexes were normal even after four to seven years' persistence of a few isolated tabetic symptoms such as lancinating pains, bladder and genital insufficiency, slight disturbances in sensibility, slight "Romberg," easy fatigue, and slight pupil sign. In another group of "rudimentary" tabes there were no subjective symptoms and nothing to call attention to the few slight objective ones which were easily discovered when sought. Another group was distinguished by gastrointestinal disturbances, not at all typical of tabes, and with only bilateral paresis of the sixth nerve and the pupil sign to indicate the nature of the affection. The *"formes frustes"* of tabes may never develop beyond the rudimentary stage, but they usually continue a progressive course. They indicate the necessity of investigating the knee-jerk and pupil reflex in every patient as a routine measure. Erb adds that tabetic symptoms need not cause uneasiness in the positive absence of syphilitis antecedents, but that with them the prognosis should be extremely reserved.

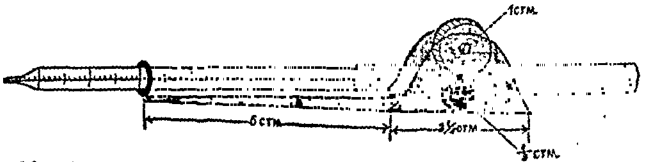
Diagnosis of Hernia of the Diaphragm. C. Hirsch.—Symptoms of gastric disturbance and congenital dextrocardia had been noted for years in the patient whose case is described in this communication. He had frequently applied for relief from the oppression and sharp pains in the left side which appeared occasionally after eating. In his thirty-fifth year he was suddenly seized with violent pain in the left side, dyspnea, vertigo and vomiting, which gradually passed away after four days, but symptoms of pneumothorax persisted, varying in intensity at different times while the general health remained comparatively good. Auscultation and percussion revealed the existence of a large hollow space in the left thorax which insufflation and fluoroscopy showed was the stomach, projecting into the thorax through a rupture in the diaphragm. A similar coincidence of hernia and dextrocardia has been reported by others, suggesting the possibility that the primary factor is a congenital defect in the diaphragm, allowing the passage of part of the stomach or intestines into the thorax with consequent displacement of the heart. Gruber found an isolated displacement of the heart in only 7 out of 100 cases of *situs inversus*. In future the evidence of hernia of the diapharagm should be sought whenever an isolated displacement of the heart is noticed.

Alcohol Dressings. C. Graeser.—The benefits of alcohol for treating phlegmonous and ulcerative processes are becoming better established every day. It acts by assembling new troops of phagocytes to repel invaders, and is especially serviceable in country practice where aseptic conditions are unattainable. The intelligent lay public can also be instructed to use alcohol compresses while awaiting the arrival of the physician.

Secret of Alcohol Disinfection of the Skin. E. Braatz.—The contradictory facts observed in regard to the efficacy of alcohol as a preliminary measure to disinfection of the hands with sublimate are explained by the results of recent tests. They demonstrated that the pores of the skin are filled with air, and that this prevents the entrance of the disinfecting fluids. Alcohol expels this air from the pores and thus enables the disinfectant to penetrate to their depths.

Vratch (St. Petersburg), July 1.

Enumeration of White Corpuscles. M. G. Kurloff.—The accompanying cut shows the principle of the pipette used to draw and measure the blood. It does away with mouth suction and ensures much greater accuracy in measuring under the eye. The compressible rubber cap on the end of the pipette runs between two wheels, which produce a vacuum and aspirate the blood to a given mark as they turn in one direction and expel the exact amount required when reversed. An assistant holds the cover-glasses ready to spread the blood to make a dried preparation at once. The corpuscles are enumerated by means of a movable cover-glass ruled into square millimeters, each set of five marked off with a heavier line, through which the dried specimen is examined under the microscope. The entire process is much simpler than the use of the Thoma-Zeiss instrument, while tests show that the results are practically identical, with the advantages that the enumeration can be done at leisure and the results controlled at any time.



Queries and Minor Notes.

MEDICAL JOURNALS?

Union Mills, Ind., Aug. 6, 1900.

To the Editor:—Please advise me where I can obtain a reliable journal on diseases of the nose and throat, and oblige. C. V. L.

Ans.—*The Annals of Otology, Rhinology and Laryngology* is a journal specially devoted to these subjects. It is published at 302 N. Third St., St. Louis, Mo. *The Laryngoscope*, also published at St. Louis, 3702 Olive St., is another journal devoted to the same specialty. Both of these can be recommended. There is also a journal published in Baltimore, the *Journal of Eye, Ear and Throat Diseases*, which is small and costs only $1.00 a year, and can also be recommended if it is large enough. For ear diseases alone Knapp's *Archives of Otology* stands easily in the first rank.

BUBONIC PLAGUE.

To the Editor:—Where did I read an article describing care of the bubonic plague at Oporto, Lisbon? S. R. T.

ANS.—There was an article, a study of the plague at Oporto, published in the *Annals of the Pasteur Institute*, July 25, 1899. We do not recall any special elaborate article, recently published, in English on this subject alone.

The Public Service.

Navy Changes.

Changes in the medical corps of the Navy for the week ending August 4, 1900:

Medical Director G. W. Woods, detached from the naval hospital, New York, August 18, and ordered home and to wait orders.

Medical Director H. J. Babin, ordered to duty in charge of the naval hospital, New York, August 18.

P. A. Surgeon L. L. Von Wedekind, detached from the *Indiana*, and ordered to the naval hospital, Chelsea, Mass., for treatment.

Asst.-Surgeon M. K. Elmer, ordered to the Boston navy yard.

Pharmacist F. T. Gordon, warranted pharmacist from July 25, 1900.

P. A. Surgeon T. W. Richards, detached from the *Machias*, when put out of commission, and ordered to the *Indiana*.

Asst.-Surgeon C. H. Delancy, ordered to additional duty at the naval hospital, Newport, R. I.

Asst.-Surgeon A. Stuart, detached from the *Yankton* and ordered to temporary duty on the tug *Fortune* at the New York navy yard.

Health Reports.

The following cases of smallpox, yellow fever, cholera and plague have been reported to the Surgeon-General, U. S. Marine Hospital Service, during the week ended August 4, 1900:

SMALLPOX—UNITED STATES.

Alaska: Cape Nome, July 1, 17 cases.

Kansas: Wichita, July 21-28, 4 cases.

Louisiana: New Orleans, July 21-28, 7 cases, 4 deaths.

Massachusetts: Lowell, July 21-28, 4 cases.

Michigan: Au Sable township, July 14-21, 1 case; Durano, July 14-21, 2 cases; Grand Rapids, July 14-21, 2 cases; Hersey, July 14-21, 1 case; Waker township, July 14-21, 1 case; Springwells township, July 14-21, 8 cases.

New Hampshire: Manchester, July 21-28, 3 cases.

Ohio: Cincinnati, July 20-27, 1 case; Cleveland, July 21-28, 18 cases.

Utah: Salt Lake City, July 21-28, 3 cases.

SMALLPOX—FOREIGN AND INSULAR.

Austria: Prague, June 30-July 14, 8 cases.

Belgium: Antwerp, June 30-July 7, 1 case; Brussels, June 30-July 7, 1 death.

England: Liverpool, July 7-14, 1 case, 1 death; London, July 7-14, 17 cases.

France: Lyons, June 30-July 7, 4 deaths; Paris, July 7-14, 3 deaths.

Germany: Frankfort-on-the-Main, June 23-30, 1 death; Königsberg, June 30-July 7, 1 case, 1 death.

Gibraltar: June 30-July 7, 1 case, 1 death.

Greece: Athens, July 7-14, 1 case 4 deaths.

India: Bombay, June 26-July 3, 3 deaths; Calcutta, June 23-20, 27 deaths; Karachi, June 24-July 1, 3 cases, 2 deaths.

Mexico: Vera Cruz, July 14-21, 5 deaths.

Philippines: Manila, June 8-16, 1 case.

Russia: Moscow, June 23-July 7, 12 cases, 7 deaths; Odessa, June 30-July 7, 5 cases, 1 death; St. Petersburg, June 30-July 14, 76 cases, 25 deaths.

Scotland: Glasgow, July 13-20, 52 cases, 1 death.

Spain: Madrid, June 2-23, 43 deaths.

Straits Settlements: Singapore, June. 2-8, 2 deaths.

Switzerland: Geneva, June 23-30, 2 cases.

YELLOW FEVER—UNITED STATES.

Florida: Hillsboro County, August 2, 2 cases.

YELLOW FEVER—FOREIGN.

Colombia: Barranquilla, July 1-14, 5 deaths; Bocas del Toro, July 26-31, 4 cases, 1 death.

Costa Rica: Port Limon, July 19, 1 case suspicious.

Cuba: Cienfuegos, July 17, 1 case on transport *Sedgewick*; Havana, July 16-23, 9 deaths; Matanzas, July 26, 1 death in barracks; Santa Clara, July 21, 2 cases.

Mexico: Vera Cruz, July 14-21, 7 deaths.

Salvador: San Salvador, June 27, present.

Venezuela: Cartegena, June 1-30, 16 cases.

CHOLERA.

China: Hongkong, June 16-23, 1 case, 1 death.

India: Bombay, June 24-July 3, 109 deaths; Calcutta, June 23-30, 55 deaths; Madras, June 23-29, 1 death.

PLAGUE.

England: London, August 3, 4 cases, 2 deaths on P. & O. S. S. *Rome*

India: Bombay, June 26-July 3, 49 deaths; Calcutta, June 23-30, 2 cases, 79 deaths; Karachi, June 24-July 1, 2 cases, 1 death.

Philippines: Manila, June 8-16, 6 cases, 3 deaths.

Turkey: Beirut, July 2, present.

New Patents.

Patents of July 17, 24 and 31, of interest to doctors:

653,989. Disinfecting block. Samuel Eden, New York City.

653,998. Cornshield. Charles B. Hatfield, New York City.

653,866. Pocket atomizer. Solomon Helman, Little Falls, N. Y.

653,687. Pill-making machine. Walter Middleditch, Detroit, Mich.

653,708. Hydro-electrotherapeutic apparatus. Johann J. Stanger, Ulm, Germany.

32,945. Design, Nerve-broach. Mathew M. Kerr, Detroit, Mich.

654,564. Surgical dressing packer. Gustav E. Dargatz, Kansas City, Mo.

654,165. Invalid's bed. Henri Leleux, Paris, France.

654,286. Ankle brace. Wm. A. Sears, Mechanicsville, Iowa.

654,185. Method of therapeutical treatment of parts of the human body and apparatus therefor. Austin V. M. Sprague, New York City.

654,581. Device for removing corns. Bernhard Wagner, Rahway, N. J.

32,989. Design, Bedpan. Mary F. Devennie, Philadelphia.

654,946. Apparatus for volatizing disinfectants. Vincenzo Cervello, Palmero, Italy.

655,060. Making non-coagulable albuminoids. Alexander Classen, Aix-la-Chapelle, Germany.

654,606. Sanitary retort. Byron Coburn, LeRoy, N. Y.

655,070. Disinfecting apparatus. Wm. H. Francis, Philadelphia.

654,832. Surgical operating table. George W. Hathaway, Lapeer, Mich.

654,906. Apparatus for examining condition of the lungs and heart. Daniel B. Marsh, Blackheath, Canada.

654,907. Pill-making machine. Walter Middleditch, Detroit, Mich.

655,008. Umbilical truss. Howard C. Rash, Salina, Kan.

654,763. Curette. James V. Russell, Chicago.

654,856. Combined support and catamenial sack. Martha E. Steele, Cowden, Ill.

Change of Address.

Dr. A. L. Anderson, from Kansas City to Oak Grove, Mo.

Dr. J. C. Ash, from Good Hope to La Harpe, Ill.

Dr. J. P. Atkinson, from 236 Richardson St. to 231 Marietta St., Atlanta, Ga.

Dr. S. G. Burkholder, from Chicago, Ill., to Denver, Pa.

Dr. G. F. Bell, from Williamsport to Newberry, Pa.

Dr. G. Betton Massey, from 1636 Walnut St. to 1831 Chestnut St., Philadelphia, Pa.

Dr. W. E. Brown, from Taylorsville, Ill., to Coolville, Ohio.

Dr. F. Blankner, from 4048 California St., St. Louis, Mo., to Potter Bldg., Grand Rapids, Mich.

Dr. S. C. Beach, from Ravenna, Neb., to Beacon, Mich.

Dr. B. Bettman, from 2522 Michigan Ave., to 2601 Kenmore Ave., Chicago, Ill.

Dr. J. B. Boucher, from 92 Main St. to 25 Charter Oak Ave., Hartford, Conn.

Dr. E. N. Brady, from 323 Western Ave., to Mary Thompson Hospital, Chicago, Ill.

Dr. C. P. Brightwell, from City Hospital to 1272 Broad St., Augusta, Ga.

Dr. A. M. Braunwarth, from 3199 to 3119 South Park Ave., Chicago, Ill.

Dr. A. Breathwit, from Kingsland to Ogamaw, Ark.

Dr. J. F. Carraway, from Rome to Church, S. C.

Dr. W. S. Caldwell, from Paris, France, to Union Bank of London, Eng.

Dr. B. L. Cleary, from 39 Laflin St., Chicago, Ill., to Sun Prairie, Wis.

Dr. C. A. Cantrell, from Valdasta to Nesbitt, Texas.

Dr. T. Coleman, from Philadelphia, Pa., to Freedmen's Hospital, Washington, D. C.

Dr. T. J. Caldwell, from 11412 Michigan Ave. to 5103 State St., Chicago, Ill.

Dr. J. R. Coleman, from Murray to P. O. Box 65, Paducah, Ky.

Dr. D. Cornelius, from 525 S. Robey St. to 284 S. Halsted St., Chicago, Ill.

Dr. Alfred P. Cole, from 37 Paint St., Chillicothe, to Ironton, Ohio.

Dr. R. E. Dvorak, from 540 W. 12th St. to 192 W. Division St., Chicago.

Dr. J. C. Dunn, from 3700 Wallace St. to 759 W. 47th St., Chicago.

Dr. D. W. Detwiler, from 1800 Wabash Ave. to 2400 Dearborn St., Chicago.

Dr. B. B. Davis, from 1610 Douglas St. to 200 Bee Bldg., Omaha, Neb.

Dr. W. L. Davis, from 433 Everett St. to 534 Minnesota Ave., Kansas City, Kan.

Dr. J. G. Eckstein, from 1135 Dayton. St., Cincinnati, Ohio, to Colorado Springs, Col.

Dr. A. Friedlander, from 22 W. 7th St. to 643 Forest Ave., Cincinnati, Ohio.

Dr. A. B. Giles, from 1340 Aisquith St. to Forest Ave., N. Walbrook, Baltimore, Md.

Dr. W. H. Grayson, from Madison, Ill., to 1357 Lucretia Ave., St. Louis, Mo.

Dr. G. J. P. Gish, from [illegible] [illegible]ng, Mo.

Dr. C. B. Hopkins, from 732 Jackson St. to 669 Adams St., Chicago.

Dr. J. W. Hewittson, from 61 Park Ave., Chicago, to Valley City, N. D.

Dr. E. R. Hawley, from The Loraine to 3746 Ellis Ave., Chicago.

Dr. G. I. Honaker, from Panther, to Duhring, W. Va.

Dr. J. G. Johnson, from Lowryville, to Chester, S. C.

Dr. F. G. Johnson, from Paoli to Sparta, Wis.

Dr. H. C. Johnson, from Fond du Lac to Manawaw, Wis.

Dr. L. D. Kaslenbine, from 923 3rd Ave., to St. James Court, Louisville, Ky.

Dr. C. S. Layton, from Detroit to Raber, Mich.

Dr. L. F. Love, from 826 12th St. to 1225 Walnut St. Philadelphia, Pa.

Dr. A. B. Lindquist, from Omaha, Neb., to 104 Lexington Ave., New York, N. Y.

Dr. R. H. Lee, from 2201 Brooklyn Ave. to Cor. Indiana and Anderson Ave., Kansas City, Mo.

Dr. E. A. Lawbaugh, from 2754 N. Hermitage Ave. to 237 LaSalle Ave., Chicago.

Dr. W. A. MacFarlane, from 962 Taylor St. to 573 Oakley Ave., Chicago.

R. J. Muenzner, from West Bend to Wabeno, Wis.

Dr. G. H. McClure, from 160 N. Avers St., Chicago, to Westboro, Wis.

Dr. E. E. Musson, from 258 S. 16th St. to 2136 Fitzwater St., Philadelphia, Pa.

Dr. S. Mener, from Denver, Col., to 124 W. 114th St. New York City.

Dr. J. G. Martin, from Hammond, La., to Brookhaven, Miss.

Dr. H. G. Morris, from Tangipahoa to Liverpool, La.

Dr. L. Morrison, from 718 Walnut St. Louisville, to Lebanon Jct., Ky.

Dr. T. T. Naae, from Fallow to Fostoria, Iowa.

Dr. R. A. McDonnell, from 312 Elm St., to 1142 Chapel St., New Haven, Conn.

Dr. R. H. Michels, 1007 W. Harrison St., to 1381 N. Clark St., Chicago.

Dr. J. H. Martindall, from 601 Figariou St. to Bellevue Terrace, Los Angeles, Cal.

Dr. C. B. Nancrede from 4 Cornwall Pl. to 720 S. University Ave., Ann Arbor, Mich.

Dr. R. L. McNeer, from 1401 W. Lafayette St. to U. S. Marine Hospital, Baltimore, Md.

Dr. J. C. Pfoff, from Slatington to 919 N. 29th St., Philadelphia, Pa.

Dr. F. A. Packard, from 110 S. 18th St. to 258 S. 18th St., Philadelphia, Pa.

Dr. T. B. Perry, from U. S. Marine Hospital, Mobile, Ala., to U. S. Marine Hospital, Wilmington, N. C.

Dr. W. A. Pursey, from 383 Superior St. to 512 Greenwood Boul., Chicago.

Dr. W. E. Potter, from 43½ Seeley Ave. to 785 W. Madison St., Chicago.

Dr. J. M. Phalen, from 951 Harrison St. to Cook County Hospital, Chicago.

Dr. A. Peacock, from 252 E. 55th St. to 348 E. 55th St., Chicago.

Dr. D. H. Pelletier, from Fowler, Ind., to St. Anne, Ill.

Dr. R. L. Pierce, from Whetstone to 220 E. State St., Columbus, Ohio.

Dr. B. W. Rogers, from Lake Geneva, to Milton Junction, Wis.

Dr. J. H. Robnett, from Salem to Union, Ore.

Dr. J. M. Rogers, from 53 Merritts St., Atlanta, Ga., to 448 New St., Macon, Ga.

Dr. T. S. Rosengrant, from Batesville to Barnesville, Ohio.

Dr. H. N. Rucker, from 668 W. 14th St. to 521 12th St., Oakland, Cal.

Dr. A. A. Shelley, from Goodland, to Abilene, Kan.

Dr. J. S. Shrader, from Delano, Minn., to Appleton, Wis.

Dr. W. J. Stewart, from Library, to McKee's Rocks General Hospital, McKee's Rocks, Pa.

Dr. W. K. Sutherlin, from Mansfield to Scott Bldg., Shreveport, La.

Dr. J. E. Smith, from Flower Creek, Mich., to Deep River, Iowa.

Dr. A. N. Sloan, from Franklin, Neb., to Samaritan Hospital, Sioux City, Iowa.

Dr. L. W. Shannon, from Chicago to Granada, Kan.

Dr. D. K. Smith, from 1400 12th Ave., to 1231 12th Ave., Altoona, Pa.

Dr. A. Shulman, from 27 E. 95th St., New York, to Arverne, N. Y.

Dr. Jokichi Takamine, from 90 Maiden Lane, to 475 W. Central Park St., New York City.

Dr. T. R. Thomas, from Stillwater, Minn., to Gomer, Ohio.

Dr. A. D. Taylor, from Williamsville to 320½ S. 5th St., Springfield, Ill.

Dr. L. C. Vincent, from 72 W. 48th St. to 101 W. 52nd St., New York City.

Dr. Wm. S. Wilcox, from Weyamvega to Park Falls, Wis.

Dr. E. E. Walker, from 22 E. Sabb St., Petersburg, to Forksville P. O., Mecklenburg County, Va.

Dr. H. M. Williams, from Emporia, Kan., to Oklahoma City, O. T.

Dr. E. W. Woodford, from 373 Jennings Ave. to 737 Detroit St., Cleveland, Ohio.

Dr. R. Williams, from Carthage, Ill., to Alden, Minn.

Dr. J. R. Winslow, from 924 Culloh St. to 114 W. Franklin St., Baltimore, Md.

THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION

61 Market Street : : Chicago, Ill.

Cable Address: "Medic, Chicago".

Subscription price: Five dollars per annum in advance

Postage in the United States and Canada, Mexico, Hawaii, Guam, Porto Rico, and the Philippines, free; foreign postage, $2.50. Subscriptions may commence at any time. Volumes begin with the first issue of January and of July.

MEMBERSHIP IN THE AMERICAN MEDICAL ASSOCIATION.

The qualifications for membership require that the applicant be a member, in good standing, of a state or local medical society entitled to send delegates to the annual meeting of the American Medical Association. A list of these societies will be sent on request. Applications must be accompanied with a certificate showing that the applicant is a member of a recognized society, and should be sent with the annual dues—five dollars—to the treasurer, Dr. Henry P. Newman, 100 Washington Street, Chicago. Members receive The Journal free. Subscribers to The Journal may become members of the Association without additional expense, if they are members of medical societies recognized by the Association. Those desiring to have their names transferred from the subscription to the membership lists should send certificates as above, with a receipt for their subscription to The Journal, covering the current fiscal year.

FISCAL YEAR.

The fiscal year of the American Medical Association is from January 1 to December 31; and the annual dues paid by a new member cover only the fiscal year, no matter at what time of year the membership is obtained. Those who pay their dues and join the Association at the annual meeting in June, for instance, pay only for the fiscal year which ends with the December following, and the annual dues for the following fiscal year are payable the succeeding January, at which time the treasurer sends a statement to each member. Such members, however, are entitled to The Journal for the full year, even though the membership be not continued.

PAPERS READ AT THE ANNUAL MEETING.

"Every paper received by this Association and ordered to be published, and all plates or other means of illustration, shall be considered the exclusive property of the Association. . . The Board of Trustees shall have full discretionary power to omit from the published transactions, in part or in whole, any paper that may be referred to it by the Association or either of the Sections, unless specially instructed to the contrary by vote of the Association." (From Article V of the By-laws.)

NEWS.

Our readers are requested to send us items of news of a medical nature, also marked copies of local newspapers containing matters of interest to members of the medical profession. We shall be glad to know the name of the sender in every instance.

ORIGINAL PAPERS.

Articles are accepted for publication with the understanding that they are contributed solely to this journal.

COPYRIGHT.

Matter appearing in The Journal of the American Medical Association is covered by copyright, but as a general thing, no objection will be made to the reproduction of anything appearing in its columns if proper credit be given.

CONTRIBUTIONS TYPEWRITTEN.

It will be satisfactory to all concerned if authors will have their contributions typewritten before submitting them for publication. The expense is small to the author—the satisfaction is great to the editor and printer. We can not promise to return unused manuscript.

Half-tones, zinc etchings and other illustrations will be furnished by The Journal when photographs or drawings are supplied by the author.

ADVERTISEMENTS.

Advertising forms go to press eight days in advance of the date of issue. Therefore, in sending in copy, time should be allowed for setting up advertisements and for the sending and return of proofs. Advertising rates will be made known on request.

CHANGE OF ADDRESS.

In ordering a change of address it is important that both the old and new addresses be given.

REMITTANCES.

Remittances should be made by check, draft, registered letter, money or express order. Currency should not be sent, unless registered. Stamps in amounts under one dollar are acceptable. Make all checks, etc., payable to "Journal American Medical Association," except those for annual dues. These should be made payable and sent direct to the Treasurer, Dr. Henry P. Newman, 100 Washington Street, Chicago.

The Journal of the American Medical Association

Original Articles.

PARTURITION AS A FACTOR IN GYNECOLOGIC PRACTICE.*

JOHN MILTON DUFF, M.D.
PITTSBURG, PA.

To convince gynecologists that parturition is not only a factor, but the principal factor, in producing morbidity which calls for their interference, no other argument is needed but the statistics of their own practice.

Not having any special statistics at my command, I can not give the percentage of the cases of gynecic practice due directly or indirectly to parturition. They, of course, vary in different communities, as well as in the practice of different gynecologists. From what I can cull from general statistics, and from my own, as well as some statistics kindly furnished me by several gentlemen of large experience, I feel justified in saying that considerably over 50 per cent. of all gynecologic cases can be charged to parturition. The statistics furnished me vary very materially; the lowest are 55 per cent., and the highest 90 per cent., the average being about 66 per cent. The percentage of those working in large general hospitals is much smaller than those having private hospitals. In my own practice, if I eliminate the cases of gonococci infection treated in the general hospital, the percentage of cases following parturition is increased over 20 per cent. In speaking of parturition, I, of course, include the large number resulting from abortions. It would certainly be very interesting, and perhaps startling, to know just what percentage of parturient women become subjects for the gynecologist. This can not even be approximated, nevertheless our observation leads us to believe that it is quite large.

Aside from inversion of the uterus and fistulas due to pressure, nearly all the morbid conditions following parturition which come to the notice of the gynecologist are primarily due to sepsis, to lacerations, or to both combined.

Having these undisputed facts before us, it behooves us to make earnest, energetic inquiry as to: 1, the best means of avoiding these primary causes; and 2, when they do occur, what measures will be the most effective in preventing the secondary morbid conditions which are liable to follow in their train. Modern aseptic and surgical obstetric practice has already done wonders in this direction. I believe the principal object of the chairman and secretary of this Section in placing this subject in the symposium, was to elicit a discussion which would show in no uncertain tones, not only the great work already accomplished along this line, but the immense possibilities it affords. I do not want to show an enthusiasm which facts do not warrant, but I believe a rigid enforcement of the rules of obstetric practice, as laid down by our best teachers and writers of to-day, would eliminate more than 50 per cent. of the gynecic cases resulting from parturition, if we except those resulting from abortion. What other proof do I need to sustain me in this than the records of cases confined in the maternity hospitals, where nowadays a case of septic infection very rarely occurs, and from which hospitals a woman is not allowed to depart with a ruptured perineum unrepaired.

In my enthusiasm in this matter I do not want to be unjust to the general medical profession, by making rash statements. At the risk, therefore, of apparently making an apology for ignorant and careless midwifery, I do not claim that we have arrived at that degree of perfection that we can, in every instance and under all circumstances, prevent septic infection. This concession does not neutralize the assertion that in almost all, if not all, cases of "septic infection," there has been a failure in the technique either by omission or commission. The assertion made by a member of our profession some time ago, that "the obstetrician who has a case of septic infection to occur in his practice is guilty of malpractice," was entirely too radical. Our sense of justice as a profession forbids our endorsing such an extravagant sentiment.

The obstetrician can not always control the general environment of his patient, nor can he be held responsible for her ignorance, carelessness, or obstreperousness. He can not make up for the imperfections of an incapable nurse, neither can he be held accountable for the sometimes dangerous interference of ignorant and superstitious neighbors and friends. This being conceded, and the fact acknowledged that septic infection may occasionally occur in the hands of the most skilful and careful practitioner, it does not militate against our claims for the effectiveness of asepsis, nor is it an excuse for the careless or indolent who fail to carry out its requirements.

There is a false idea among a large portion of the laity that a laceration is always significant of a lack of skill on the part of the attendant. This notion is ratified by that class of accoucheurs who never have a laceration to occur in their practice, and who never have a *morbidity or mortality to occur after a confinement* attended by them—a class with whom I have no patience. They help bring unmerited odium upon able and conscientious fellow practitioners. I can not speak more kindly of such than to say that their practice is either very limited, or they fail to search for lacerations. It is certainly no disgrace, and ordinarily no reflection, on the ability of the accoucheur, to have a laceration of the cervix or perineum to occur. Of course, complete lacerations of the perineum, though sometimes unavoidable, are comparatively rare; but I believe that, even in the practice of the most accomplished obstetricians, at least slight lacerations in primiparæ are the rule rather than the exception.

---

*Presented to the Section on Obstetrics and Diseases of Women, at the Fifty-first Annual Meeting of the American Medical Association, held at Atlantic City, N. J., June 5-8, 1900.

I am convinced from my observations that men frequently allow a lacerated perineum to pass unannounced, and without repair, because of the fear that a knowledge of it would cause a reflection on their skill. To such I say: "Their reputation is liable to suffer subsequently tenfold more by a failure to attempt a repair." I use the word "attempt" advisedly, for it is not always possible to secure prompt and perfect union. While a woman has no right to chide her attendant for a laceration where he has used ordinary care and skill, she has a right to condemn him if he wilfully leaves her to endure the manifold evils which are liable to result from an unrepaired lacerated perineum. The instances are very rare indeed where he is justified in neglecting an immediate repair of the perineum, and just as rare where he should fail to advise the repair of a lacerated cervix at the earliest possible period after the puerperium.

Notwithstanding all of the excuses or concessions I have already made, it is certainly an undeniable fact, that very many more women are doomed to a life of morbidity than should be, with our present resources. This may, to a certain extent, be the result of incapability or carelessness on the part of the practitioner, but as a rule the skill and honesty of the physician is beyond reproach. Methods of practice and ignorance on the part of the laity are largely responsible. The general notion that the obstetrician is a mere midwife, whose duties begin with the onset of labor, and end with the delivery of the placenta, is preposterous. It is as much his duty to care for her during her pregnancy, and prepare her for the trying ordeal of labor, as it is to conduct her through that important event. Again, it is equally as necessary for him to follow her through the puerperium and to the completion of involution.

Upon a subject now so well understood as asepsis, it is unnecessary for me to go into minutiæ, and yet there are a few points in this connection, to which I wish to call attention. First, the day of antiseptic midwifery is past. Notwithstanding its many defects, it was necessary in the course of evolution to a more perfect technique. To-day we know its principles are not only directly harmful, but a neglect of asepsis, with a dependence upon antiseptics to right wrongs, is not only unscientific, but cruel and murderous. The true antiseptics are the normal and healthy secretions of the body, and especially that greatest of all germicides, the blood. Hence the necessity of due attention to the secretions and to the condition of the blood previous to the onset of labor. In instituting aseptic precautions before labor, the douching of the vagina with antiseptics is not only useless, but harmful in a healthy woman. And in an unhealthy vagina, with pernicious secretions, it is not effective. Where it is necessary at all to cleanse the vagina, it should be scrubbed and prepared as carefully as if one was about to do a vaginal hysterectomy. The normal secretions of the vagina ordinarily make it uninhabitable for septic germs. The normal and safe habitat for them is the vulva, and it should undergo the most careful cleansing possible.

A cause of infection, through putrefaction, is a failure to remove all placental tissue and membranes. For this reason, a careful examination of the placenta should be made on all occasions to determine its complete removal. In this connection, I want, in the most emphatic manner possible, to call attention to a matter of the gravest importance, which I am led to believe does not receive that consideration it deserves by the profession. I refer to the placenta succenturiata and placenta spuria. I am convinced that they not only exist very much more frequently than is generally believed, but that they are frequently the direct cause of sepsis that can not be accounted for. In two autopsies with which I am acquainted, one of them being in one of the most prominent women of our city, a spurious placenta was found. On at least five occasions I have found them.

Comparatively little has been written on this subject, and I hope I have said enough to awaken a spirit of investigation upon it. While I have not time to discuss the matter at length, notwithstanding the very able paper maintaining the other side of the question, read by my worthy friend from Philadelphia, at the Milwaukee meeting in 1894, I am still of the opinion that "the routine practice of administering ergot after the third stage of labor," as set forth in a paper read by me before the Pittsburg South Side Medical Society, and published in the *Therapeutic Gazette* of July 15, 1892, is pernicious, and is frequently the cause of the woman being placed in the gynecologist's chair.

The too early resumption of household cares and duties after labor and before involution is complete is, I think, accountable for many of the malpositions and their concomitant disorders which we encounter. This matter, however, is elucidated in the paper of Dr. Vineberg, and I will not dwell upon it.

Inasmuch as I have performed the duty assigned me of opening the discussion, I shall leave it for others more worthy to discuss it. In conclusion, I have only to say that by a rational midwifery such as I have suggested, with careful asepsis and proper and timely repair of lacerations, salpingitis, ovarian abscess, and endometritis would be less frequent, and prolapsus uteri, vesicocele and rectocele, with all their accompanying phenomena, would be comparatively rare.

515 Penn Ave.

DISCUSSION.

Dr. Morcedai Price, Philadelphia—I wish to endorse the Doctor's method of treatment. He is the only man in this state who has always advocated good obstetrics. I wish to say that nine out of ten cases of puerperal fever referred to me have been caused by the useless, worthless and dangerous use of antiseptics. The condition of the medical men to-day, in regard to obstetrics, is that they have microbes in mind all the time. They need to be washed and cleaned. I have seen temperatures of 103 and 104 from intrauterine irrigation after labor and from the use of the curette. These two things have come to be the fashion in all cases of labor. The mortality and the danger following such procedures is probably the result of at least 50 per cent. of the deaths from puerperal fever. I have in many instances asked the attending physician to discontinue with antiseptics and washings and the result has been all that could be asked for. In one case I was persuaded by an overwhelming majority, in a consultation, to use a douche. They had irrigated the vagina and asked me to irrigate the uterus. I asked them to give a twentieth of a grain of strychnin, but they insisted on my using the douche. As a consequence we spent the night with that woman trying to save her from the effects of the douche. It is the cause of more disastrous results than any other practice.

I endorse the Doctor's paper without hesitation and believe that if the profession will read and adopt the methods recommended by him, the mortality in obstetric cases would be lessened. It is greater to-day than at any other time in the course of my professional career of thirty odd years. The profession must unlearn all the nonsense taught them in the past, and it will take just such papers as that of Dr. Duff to teach them the proper method.

Dr. L. H. Dunning, Indianapolis—I most heartily endorse the paper. Dr. Duff has stated his point forcibly, although not too strongly. I have often seen what he has pointed out, especially the disastrous results following the use of too strong bichlorid douches. I recall a case seen a few days ago, in which the patient had a temperature of 101. The doctor became alarmed, gave a bichlorid douche, which was followed by shock and an almost fatal issue. Withholding the douche, on my advice, resulted in the recovery of the patient.

The point I specially wish to mention, and which is of considerable importance, is the fact that a large percentage of the cases coming into the hands of the gynecologists are the result of parturition. There is one class of cases which comes to use which could readily be prevented, cases of displacement due to subinvolution. We have all been taught that every case of laceration of the perineum should be attended to at once. While we all believe in treating lacerations conservatively, many general practitioners ignore this point. I do not suppose that immediate repair of a laceration of the cervix has always been satisfactory, but I do believe that the case ought to be examined six weeks after the delivery, and if a laceration is found it should be promptly attended to. If allowed to go on it will in many instances result in imperfect involution, displacements, marked congestion of the pelvic organs and chronic invalidism. The care of the woman delivered should not end until the cervix has been attended to and until involution has properly taken place.

Dr. Joseph Price, Philadelphia—The practice of midwifery in private and public differs more or less. The practice in private has degenerated tremendously. We are not as enthusiastic as we were a few years ago. I remember the time when obstetricians entered into all of our discussions with considerable enthusiasm. To-day the reading of an obstetric paper is the excuse for men to leave the session. The professor of obstetrics sits on two stools. Every obstetrician in America seeks an appointment in school to teach obstetrics while he is practicing gynecology. Nothing is more unfortunate for women than the fact that we have no enthusiastic specialists in obstetrics. You can not very well follow the same methods in public which you do in private. Very few households will permit the practice of well-organized and disciplined maternity work. The syringes commonly used in private houses ought never to be used by the obstetrician. Unless the physician has his own syringe he should never use the one hanging behind the bath-tub. That syringe is used by everybody and is sometimes the source of infection of the entire household. While the wife or mother is down-town shopping the maid or cook will surely use it. I have tried to educate my patients to the importance of locking up their syringes just as they do their jewels. In the maternity the vaginal douche, ante-partum or postpartum, is good practice, as these patients are usually much dirtier than private patients, who take better care of themselves.

The indiscriminate use of the curette is little short of being criminal. A woman sometimes develops a little temperature and the doctor thinks he must use the curette. After having done so he is no better off than before and really does not know what he has done it for. Nearly all the cases which I have seen a few days after curettement, still have some pieces of membrane left in the uterus. Dr. Duff fortunately presents such valuable papers at nearly every meeting of our Association, and we owe him a debt of gratitude for pounding away at obstetrics at such an opportune time as the present.

Dr. C. A. Ritter, Kansas City—The science and art of obstetrics, implying in its broadest sense the care of woman during gestation, labor and the puerperium, has, until the recent past, been sadly neglected. The numerous papers on the program of this section dealing with gynecologic subjects, the few on obstetric, indicate to some degree the tendency of the medical mind of to-day. More scientific and careful obstetric work means fewer invalids, and lessens the necessity of gynecologic interference. The frequent practice, on the part of the young graduate—unless thoroughly trained in clinical work, and not altogether absent among the older members of the profession—of frequent vaginal examination, and c[illegible]less interference during normal labor; the use of th[illegible] and post-partum douche in the absence of pathological conditions; the failure in immediate repair of injuries to the vagina and pelvic floor, are fruitful sources of infection. Hence many mothers endure a mild or more severe attack of sepsis, have an unsatisfactory puerperium, a "bad getting up," and at no distant date, consult the gynecologist for surgical relief. With temperature and increased pulse-rate during the puerperium we should interrogate other organs besides the uterus for source of trouble.

Frequently the thorough evacuation of the contents of the alimentary canal by the free use of saline cathartics will be followed by normal temperature and pulse. I agree with the author in his statement that there is danger of using too strong germicidal remedies about the parturient canal. To be clean, to be aseptic, should be the alpha and omega in the care of the parturient patient.

Dr. A. B. Miller, Syracuse—I regret that I was not present when Dr. Duff read his paper, but from the discussion it seems to me that we are not treating the subject under discussion as we should. For us to deal with the sky parlor in obstetrics, instead of coming down to the real facts, is not going to diminish or decrease the mortality in obstetrics. The fact that everybody uses the syringe is not the source of the infection in cases of obstetrics; the infection is carried usually by the physician in attendance. If he has been attending a pus case, a streptococcus infection, our patient will in all probability be infected and is surely going to die. If we practice bacteriology and recognize that these infections are based on specific poisons, then we shall know of the possibility of our patient's recovering. If we have a staphylococcus infection the larger percentage of cases will recover, but if we have a streptococcus infection the case will in the majority of instances die. Cases of mixed infection will also die. In my practice, instead of resorting to the curette or irrigating the vagina or uterus, I determine as soon as possible the source and kind of infection with which I am dealing. If due to the presence of putrefactive material in the uterus, irrigation and the curette will do good because we are removing the products of infection and we are overcoming the progress of the infection. If we have septicemia, due to a streptococcus infection, the majority of patients will die; and if due to the bacillus coli communis, it is of little consequence.

As to the silver ointment I regret to say that while several cases have come under my care, I have seen but little benefit from its use. It is all important to ascertain the source and kind of infection with which we are dealing. If we have a pus tube from an old infection, that patient is not going to be benefited by the use of the douche or the curette. It requires something more than that.

Dr. Albert H. Tuttle, Cambridge, Mass.—If we consider parturition as one of the most important factors in the production of diseases of women, we must study how we should treat cases of parturition so that we will avoid as much as possible the complications which may result. It resolves itself into two stages. The first stage should be the preparation of our patient before the delivery, and we must consider that almost every case of parturition will be attended with the production of lesions of the parturient canal. This will, in many instances, mean large tears, complicating the deeper structures of the pelvis. In other cases there will only be moderate abrasion, but still capable of carrying infection. Consequently, we should prepare a patient for parturition in as careful a manner as we would for an abdominal section or a vaginal hysterectomy; that is an important factor. I know of no obstretician in my immediate vicinity who makes any preparation of his patient more than to use a vaginal douche. Many of them object to that, saying that a douche before delivery interferes with the normal secretions of the vagina and also interferes with delivery itself.

The other consideration is the careful examination and repair of the parts immediately at the close of labor. It is almost an impossibility to find a primipara who goes through labor without more or less of a tear. There may [illegible] a [illegible] gash, which ap[illegible] but when [illegible] and look [illegible] lacerat[illegible] [illegible] up to [illegible] up [illegible] space. Others may start at the cervix and from a similar lesion. These injuries are generally productive of severe infection with adhesions and fixation of the uterus. The infection in other cases may be mild or severe, depending on the character of the germ present. If the infection is due to the streptococcus you are almost sure to lose your patient. There are two things which should be borne in mind, namely, make a careful preparation of your patient beforehand and carefully examine the vagina and uterus after parturition, cleaning out all clots in the uterus and making a complete surgical repair of the injured parts. If the obstetrician is not able to do this himself, he should call in a neighboring physician who can do it.

The complete surgical repair of the injuries of parturition is of the utmost importance for the health of our women and the prevention of severe pelvic disease.

Dr. E. G. Zinke, Cincinnati—I have no doubt that the majority of those present know how to prevent sepsis during and after labor. I do not doubt that the majority of us thoroughly understand when and when not to irrigate, before, during or after labor; when and when not to use the curette, when to use the sharp and when the dull curette. The trouble lies elsewhere and it was pointedly stated by my friend Dr. Price, of Philadelphia. The obstetrician of the present day does not hold the position he should and there is a very good reason for it, because it does not pay to be a specialist of obstetrics. There is not money enough in it to pay a man to devote his attention exclusively to the practice of obstetrics and there lies the fault.

Everybody who has graduated, who has received a course of study as we now have it, thinks he knows all about obstetrics. I have seen men who have told me that they never saw a fatal case. They do not know what it is to have a case of puerperal sepsis or a badly torn perineum. In my part of the country, men attend cases of confinement for from $5 to $20. A man who charges $25 is looked upon as a robber, and the man who charges $50 is left strictly alone.

I hold the chair of obstetrics in our college and I am bound to practice gynecology in order to pay my debts. It is well to look these things in the face. The chair of obstetrics ought to be endowed. A good college ought to pay a man $5000 a year to teach such a branch. Then they could demand of him that he give the subject his entire attention, and I, for my part, would be willing to do it.

The profession, too, is largely to blame, because every effort that men have made, with the view of establishing maternities or out-door clinics have been damned by the profession abroad and in their immediate vicinity. I remember years ago when I started an out-door clinic in Cincinnati. I had great difficulty in obtaining the permission of the faculty to do so for fear the college would receive unpleasant notoriety, and not without good cause. The first obstetric clinic was established in Boston, and the founder of it had to leave the city in order to save his life. The first attempt to deliver a woman before a class was served in the same way. To-day, a man connected with a maternity or out-door clinic is looked down upon by his brethren. If you want to teach obstetrics thoroughly and practice it as it should be, all these things must be taken into consideration. Every man is doing the best he can, and you can not blame him if he practices other things which he understands just as well, and does not limit himself to the department he occupies simply because it does not seem right to some.

Dr. Duff (closing the discussion)—I would like to say much on this subject and would like to have said it in my paper, but I had to make it short, simply striking the notes and giving you the tune. You all know that the subject of obstetrics has not been a popular one. I have found this out for several years. I teach obstetrics and try to do so to the best of my ability, but I have to practice gynecology to make a living. I am sometimes called out fifty miles into the country to help a man out in a case. I lose much time and money in making this call, and when I meet the doctor at the depot he will probably tell me that "this is a poor man and he can not pay anything," and all I get for my time is my expenses paid. A man can not practice obstetrics alone; he can not take the necessary time; he can not have the armamentarium.

As to infection, we are coming to the day when we will consider septic infection as I have discussed it in my paper. The days of aseptic obstetrics are coming. We must use prevention in obstetrics as we do in other operations. We should not be careless beforehand and then try to remedy it afterward. Neither should we invade the territory in order to defend it, when there is no infection present in it.

A short time ago, I saw a case of septicemia in consultation with two other gentlemen. The lady had a temperature of 107, and the pulse I could not count. I made a digital examination and found placental tissue in her uterus. I called the attending physician aside and asked him whether he had all of the placenta. He said "yes" and even exhumed the placenta in order to prove it. On examination, I found that there was a placenta succenturiata as large as my hand. The case I refer to in my paper had sepsis. The doctor said he had taken the pieces all out, but on the autopsy we found a placenta succenturiata. I have seen five cases of this myself, and I have met others who have found them as well. There is very little in the literature on the subject, and I hope it will be considered more carefully next year so that all cases of this kind may be recorded.

I should like to talk along this line for a long time, but I hope that the spirit engendered here this morning will grow, and that the obstetrician will come here, read his paper and become popular instead of being an excuse for a man to slip out of the room.

ANTEFLEXION OF THE UTERUS; ITS CAUSES AND TREATMENT.*

AUGUSTUS P. CLARKE, A.M., M.D.
CAMBRIDGE, MASS.

Anteflexion of the uterus may not infrequently be regarded as a symptom of an undeveloped condition of the genitalia. The state is, no doubt, in many cases, congenital in its manifestation, or is early superinduced by exposure of the subject to faulty hygienic surroundings. Improper modes of dressing during the years of childhood and before puberty have been ascribed as an important factor entering into its causation, but it is often difficult to appreciate how the normal intra-abdominal pressure can be so modified as to cause, to any great extent, before the vulvovaginal introitus has been affected by the influences of parturient processes, displacement of so small an organ as the uterus, which, for the most part scarcely measures by the sound two and one-half inches in depth.

The uterus, including its cervix, sustained in its proper position by the uterosacral ligaments, with the axis of the corpus assuming with that of the cervix an obtuse angle, can not be said to present a condition manifesting pathologic phases, unless there is an accompanying dysmenorrhea or there are marked vesical symptoms. Such a condition of the uterus does not require treatment, unless there has been exhibited a tendency to a greater displacement of the organ, or there is an associated inflammation, or a morbid process in adjacent structures. When the axis of the body of the uterus forms with the axis of the cervix an acute or a right angle, pathologic symptoms, more or less severe, are almost always present.

Cervical anteflexion is largely due to habitual constipation; this is more apt to occur in girls at the beginning of their menstrual period, when the lower portions of the uterosacral ligaments are in a soft and yielding condition. For this reason, treatment for healthful regularity of the bowels in such subjects should at as early a date as possible be commenced and persevered in.

---

*Presented to the Section on Obstetrics and Diseases of Women, at the Fifty-first Annual Meeting of the American Medical Association, held at Atlantic City, N. J., June 5-8, 1900.

Besides the influence of excessive accumulation of fecal matter in the rectum or sigmoid flexure of the colon, frequent and long retention of the urine in the bladder is a most prolific predisposing cause. Girls should be admonished that shorter intervals for micturition are absolutely essential; particularly is it so with those who are compelled to stand much, or to take long rides, or who during the hours of the night take regular sleep after undergoing fatiguing or wearisome exercise. I have been noticing for some years the influences of such factors, and have come to regard them as matters of no small importance. American girls, from sheer modesty or from overindulgence in notions regarding the necessity of complying strictly with what may be termed the morbid conventionalities of society, have too often become the victims of vesical inflammation and distention, which have laid the foundation of cystocele and the more serious forms of anteflexion.

Prolonged mental strain, to which young females are habituated in our public schools and higher educational institutions, tends to render functionless the genitalia, or to deprive those parts of the necessary pabulum for their proper anterior development, by determining the influences of such aliment to the brain or central nervous system for the special display or attainment of cerebral activities.

In the fetus the cervix is earlier developed than is the corpus uteri; so also does the posterior portion of the uterus advance in earlier life faster than the anterior part. This we may often see by noticing the thinness of the anterior portion as compared with the thickness of the posterior aspect of the cervix, or of the lower segment of the body of the uterus.

The cause of this may satisfactorily be found when it is observed that in the females of some of the lower placental mammals the two uteri formed out of the lower portion of the Müllerian ducts remain separate, while in the higher orders of the same group the organs unite and form but one. The process of union, according to Gegenbaur and Haeckel, proceeds continuously and gradually from behind and below, upward and forward.

It may be said, therefore, that conditions which would lead to an imperfect growth of the sexual organs generally would make their influence become more manifest by the effect that would result on those parts, like the anterior segment of the uterus, which are slowest in their formation.

While we do not know as yet why menstruation has become necessary, we have been able to determine that it has been the outcome of the earlier evolutional processes, as its phenomena or its analogue are seen in certain grades of the higher kinds of placental mammalia.

The force of one fact we can fully realize is that whatever functional attainment has come through the long course of ancestral development should not be abruptly interfered with, for the organism has largely accommodated itself to its operations; and its harmonious working according to its own impulse, received through heredity, is almost absolutely essential, for the time being at least, to the preservation of the higher physical and mental activities and to the all-roundness of the individual.

As already intimated, contraction due to inflammation of the anterior wall of the uterus, at or near the junction of the cervix with the corpus, may be a cause of anteflexion; this occurs when the inflammation of the part has been the result of an extension of inflammation from the bladder or other portion of the urinary apparatus.

The weight of a fibroid or other tumor in either wall of the uterus may be accompanied by anteflexion but such a state can hardly be regarded as a typical form of flexure of the organ. If the influence of the pressure, however, produces a concavity of the uterus anteriorly, permanent flexion in that direction may follow as a result of the interference with the nutrition of that part of the uterus.

The formation of peritonitic adhesions anteriorly to the uterus is sometimes undoubtedly the cause of the forward flexion of the organ; this would be especially a factor in those cases in which the uterosacral ligaments are firm and unyielding or have become unduly shortened or contracted from any cause.

Endometritis, alteration of the utricular glands, atrophy of the submucous connective tissue, disordered condition of the vascular element are sometimes prolific sources of anteflexion.

In a case of a young woman aged 19 years, who had marked anteflexion attended with dysmenorrhea, there was a preternatural enlargement of the veins in and about the meatus urinarius. The veins in the anterior vaginal fornix had also become varicose and were much more numerous than was normal.

In many, if not in most, cases of anteflexion of the lesser type, the condition is merely physiologic in its general aspects, while in other forms it results from affections of the appendages, as from salpingitis, ovaritis, or extension of the inflammatory processes to the anterior walls of the uterus. This was exemplified in the case of a young woman aged 17 years, who had received an injury from a fall on the anterior portion of the pelvis; the accident was subsequently followed by the occurrence of dysmenorrhea and a well-marked anteflexion; pain and febrile disturbances lasted some six weeks immediately preceding the flexion.

The influences of degenerative changes in the cervical glands upon the submucous tissue and upon the muscular structures about the os internum are not infrequently productive of atrophy of the adjacent parts. Such a state unfits in large measure the structures for sustaining the corpus uteri; the condition is liable, in unmarried or in childless women, to be followed, through faulty postures which they may repeatedly assume, by the occurrence of a considerable degree of anteflexion. As said before, whatever tends to reduce unduly the general tone of the organism during its formative stage, as the lack of proper diet, may be productive of the flexure. Hyperemia, uterine catarrh and metritis resulting from mental overexcitement, cinædia or sexual perversion will often serve to weaken the uterine tissue and thus become a cause. Attacks of gonorrhea, subinvolution following abortion occurring at an early age of the patient, parametritis and cellulitis are all liable to be productive of softening or relaxation of the uterine parenchyma, and so give rise to the affection. Physical overactivity during the stage of engorgement of the organ, about the time of the occurrence of the menstrual flow, becomes an exciting cause.

It should be again said that cystitis and other morbid conditions occurring at an early age not infrequently become a factor entering into causation. In most cases of anteflexion the connec[illegible] f t[illegible] dder with the uterus are pretern[illegible] dhood t[illegible] internum is situate[illegible] han it later years; if, therefore, while the corpus is in a state of growth and development, any factor should have occurred to interfere with the normal length or with the elasticity of the uterosacral connection it will of necessity project forward upon the parietes or fundus of the bladder. Perhaps, in cases of the more serious variety, the wearing of improper dress or heavy skirts may, by modifying the intra-abdominal pressure, act as exciting causes.

Among the other causes of anteflexion which may be mentioned are: venereal excesses after marriage, criminal abortion, prolonged and instrumental labor—this to effect delivery before the full term may result in violence to the bladder or to the vesicouterine ligaments—and the all too prevalent means adopted to prevent conception or to overcome the same during its earliest stages. These influences tend to produce congestion or inflammation of the uterine tissue and contraction or inelasticity of the uterorectosacral ligaments, as before remarked.

As regards treatment, it is necessary to consider carefully in each case the predisposing cause. In a large class of cases the ora will be found preternaturally small or contracted. In such instances rapid dilatation, when faithfully performed, at the proper time, will be of much service. The operation straightens and strengthens the uterus.

In a few cases in which vesical symptoms were the disturbing features, the insertion and wearing of a properly fitting Hodge pessary were found to be of much advantage. Prolonged horizontal posture, the daily use of hot vaginal douches and the free administration of laxatives have been found beneficial as supplementary means for relief.

Marriage and encouragement of pregnancy for effecting a cure have had their advocates. Concerning the wisdom and advisability of such a step, I have some misgivings. A young woman whom I treated some years ago for anteflexion of the third degree received much benefit from the use of a Hodge pessary and of other means which I have mentioned. She was of good family; she had a soft, relaxed tissue generally. Country life and favorable hygienic surroundings added greatly to her comfort and restoration. She subsequently married and had a fair recovery after her first confinement. Her second labor, which occurred a few years after the first, was followed by a fatal attack of puerperal septicemia. After her marriage and removal into the country, during each time of her parturition, she had received skillful treatment, but she was unfitted to endure the strain consequent on her last sickness. I was called in consultation some hours before her death. There was no extensive laceration of the parts, the uterus, though empty, was found soft, relaxed and flabby. The uterine sinuses were choked with small coagula and the vessels beyond contained numerous points of embolic occlusion. Had this woman remained single, instead of exposing herself while possessing such relaxed and delicate tissue, to the risks and exactions of marital relation, she would undoubtedly have been able to have led a life of much credit and honor to herself and of advantage to her community.

For overcoming the hemorrhagic tendency curettement after dilatation of the uterine canal is most helpful. Tampons of iodoform gauze and the application of glycerin and ichthyol are in some cases excellent adjuvants.

In cases in which the active inflammatory processes have been brought under control, the use of Cutter's or Thomas' intrauterine stem pessary will sometimes be found worthy of trial.

My experience in the employment of Sims' discission of the posterior lip and in that of amputation of the cervix is far from being favorable for the indorsement of the practice. Recently there has come under my care a case in which such amputation had been resorted to for anteflexion. The patient presents a condition that may be regarded as anything but pleasant to contemplate. The corpus has become dilated and globular. The inner os appears as a mere fistula, which closes at intervals, and thus causes retention of fluids; when the os opens spontaneously or is dilated artificially the condition of the uterus resulting markedly interferes with the intra-abdominal pressure. In some cases, after rapid dilatation and curettement, I have found that gradual straightening of the canal by use of the sound or sterilized bougies proves of much benefit. Rapid dilatation, performed so as to straighten and shorten or broaden the uterine canal, followed at the time by thorough curettement, will frequently afford much relief. This should be supplemented by the frequent employment of gradual dilatation and by the patient's wearing at intervals between the menstrual periods a stem pessary. In those cases in which the ovaries and tubes have become adherent about the uterosacral ligaments, these should be separated, if possible, after all active inflammatory processes of the endometrium and other parts have been overcome, by resort to bimanual rectovaginal manipulation, and by the free use of tampons saturated with ichthyol and glycerin. In those cases in which cystitis has been a prominent symptom, from position or weight of the uterus, the use of a properly fitting pessary, after the acute stages have yielded, will become an essential means of relief.

A FEW OBSERVATIONS ON THE EFFICACY OF PROTARGOL IN PYOGENIC AFFECTIONS OF THE EYE.*

F. C. HOTZ, M.D.

Professor of Ophthalmology and Otology in Rush Medical College. CHICAGO.

Neisser, who was the first to test the germicidal activity of this new silver salt, found that a solution of 1:2000 prevented the growth of bacteria, while silver nitrate stopped their growth in a solution of 1:5000; but while the latter showed the greater germicidal power in the test-tube, protargol showed a greater penetrating power in the tissues, since it was not precipitated by blood-serum and other fluids containing albuminous compounds. Numerous clinical observations have fully confirmed the germicidal activity of protargol. I will refer only to the reports of Darier, one of the first and warmest advocates of this new remedy, who submitted a very interesting summary of his results to the last International Ophthalmological Congress in Utrecht.

Clinical experience, however, has not only proved protargol to be as efficient as argentic nitrate in the treatment of pyogenic affections, but has discovered in it valuable properties not possessed by silver nitrate. All observers agree that protargol, even in strong solutions, causes but very little irritation, and has no caustic effect. This is an advantage of inestimable value, because it permits its free use under conditions where the application of silver nitrate, on account of its irritating and caustic effect, is either positively forbidden or admissible only under the greatest precautions. We all know, for instance, how cautious we have to be in the use of argentic nitrate in the first days of an acute gonorrheal conjunctivitis; how disastrously its application may operate if one neglects to protect the cornea against contact with the solution. How different with protargol! Whatever the strength of the solution it does no harm to the cornea and therefore may be applied boldly and without fear of letting it come in contact with any part of the eye. Let me illustrate:

---

*Presented to the Section on Ophthalmology, at the Fifty-first Annual Meeting of the American Medical Association, held at Atlantic City, N. J., June 5-8, 1900.

March 24 a woman 44 years old consulted me about an inflammation of her right eye, which had begun two days before and had all the ear-marks of a violent acute gonorrheal conjunctivitis: great swelling, redness, and tenderness of the lids, so that the eversion of the upper lid was very difficult and painful; chemosis of the ocular conjunctiva, croupous coating over the tarsal conjunctiva, and a copious discharge of a whey-like secretion containing numerous gonococci. Now, in this early stage of gonorrheal conjunctivitis we religiously abstain from the use of nitrate of silver; but I did not hesitate to apply protargol at once. A cotton swab well charged with the solution—20 per cent.—was passed under the upper lid well up to the fornix and rubbed back and forth over the conjunctiva. In the same way the lower cul-de-sac was treated, and during these manipulations the protargol spread quite freely all over the eyeball. Thirty minutes after the treatment the lids were noticeably paler and less swollen, and the patient experienced a sensation of great relief. The application was repeated in the evening and twice on the following day. March 26 the lid-swelling and chemosis had disappeared; the tarsal conjunctiva was free from fibrinous coating, and the secretion showed a mucopurulent character, still containing gonococci but in much smaller number. From this day on the 20 per cent. solution was applied only in the morning and a 5 per cent. solution instilled by the patient's nurse in the afternoon and evening. On March 31, the discharge was very scanty and free from cocci; and on April 7 it was recorded that the last four days there had been no discharge. Thus in less than two weeks the eye had recovered from a violent gonorrheal infection.

With equal success protargol asserted its germicidal power in a number of suppurative inflammations of the tear-sac. A few injections usually were sufficient to stop the purulent secretion. One of the most striking instances was the case of an Irishman, 52 years old, with an acute suppurative inflammation of the tear-sac of three weeks' duration. The left side of his face was made hideous by the redness and enormous swelling of the lids and cheek, and by a large ragged wound over the tear-sac, from which pus was freely oozing. Protargol was injected into the sac, and also thoroughly rubbed with a cotton swab over the walls of the fistulous canal. In three days the swelling of the face and lids had disappeared and the pus discharge had ceased, and healthy granulations covered the wound.

In suppurative keratitis protargol has done excellent service. I unhesitatingly place it at par with the electro-cautery; and while the latter requires a special apparatus not always at the disposal of every physician, and special skill and judgment in its use, the application of protargol requires no special precaution and may be made by a nurse or almost anybody after being shown how to do it. When physicians are once acquainted with this remedy I believe many eyes will be saved which now are lost because the patient can not get the services of a specialist.

This opinion is based upon the experience in a dozen cases treated during last winter. In all cases the suppuration was checked promptly, and if the destruction of the cornea had not gone too far before I saw the case, the eye recovered with a small leucoma. In two cases the whole cornea was already involved, and, of course, could not be saved, though even here the protargol effectually stopped the further progress of destruction. The following two cases may serve as illustrations:

Case 1.—Railroad laborer, 32 years old, left eye struck by piece of coal November 15, admitted to the Presbyterian Hospital, November 22, in this condition: Swollen lids, marked chemosis, mucopurulent discharge, central portion of cornea cloudy and enclosed in a ring of pus infiltration, and a small hypopyon. Protargol was applied to the cornea as well as to the retrotarsal folds, and atropin instilled.

November 23, lid swelling and discharge greatly diminished; pus ring in cornea less marked. November 24, lid swelling and chemosis gone, no more discharge; in place of the ring there was a clean shallow groove. December 4, patient left the hospital with a rather slight central opacity in the cornea.

Case 2.—A physician came to me December 23, with a central ulcer in the cornea of his left eye; margin infiltrated, surrounding cornea cloudy; small hypopyon, irregular pupil, several posterior synechiæ. Inflammation began three weeks before, and had been treated chiefly with atropin and hot fomentations. Protargol was thoroughly applied to the ulcer. December 24, patient free from pain; slept the first time in three weeks without opiates. December 26, ulcer clean; hypopyon gone. January 6, ulcer healed.

It will be of especial interest to the members of this Section to learn that protargol was found equally efficacious in pyogenic infections after operations. In two cases of normal extraction with iridectomy the wound was not yet closed at the end of the first week. On the eighth day the eyes suddenly presented a great swelling of the lids and chemosis, mucous secretion, infiltration of the wound edges, cloudy cornea and severe pain. In both cases the first effect of the application of protargol was the almost instantaneous alleviation of the pain and the marked decrease of the lid swelling, chemosis and discharge. In the one case the suppuration did not spread beyond the wound edges after treatment was begun, and in two weeks the eye had recovered. In the other patient the symptoms were as violent as in beginning panophthalmitis, and I believe I owe it to the protargol that this eye was saved at all, though with much loss of corneal tissue and occlusion of the pupil.

Six weeks later I again had a case in which the wound was still partly open on the sixth day after extraction. With the experience of the two cases of late infection still fresh in my mind, I was naturally very anxious to see the wound closed and to forestall infection. I, therefore, touched it thoroughly with protargol, which I was satisfied would disinfect without irritating. Two days later the wound was sealed up, the anterior chamber restored, and the healing proceeded in a satisfactory way.

In summing up my experience I may say that protargol is undoubtedly a very valuable remedy in the treatment of pyogenic affections, but the results are largely governed by the strength of the solution and the frequency and mode of application. During the acute period of pyogenic inflammation the solution should be not less than 20 per cent., and applied at least twice in twenty-four hours; if no decided improvement is noticed, either the strength of the solution or the frequency of application should be increased. It is very essential that the protargol be brought in thorough contact with the affected tissues, and this is, I believe, best accomplished by means of a cotton swab, well saturated with the solution, firmly rubbed over the affected portion of the cornea and conjunctiva, especially the retrotarsal folds. On account of its non-irritating and non-caustic action it is unnecessary to wash the eyes with salt solution or to apply cold compresses after the treatment; nor is it necessary to evert the lids for the treatment of the tarsal and retrotarsal conjunctiva, an advantage greatly appreciated by patient and physician if the lids are much swollen and the eyes very sensitive.

DISCUSSION.

Dr. L. Webster Fox, Philadelphia—In 1898 I first used protargol in a mild form of purulent ophthalmia and the result obtained led me to believe that at last we had obtained a remedy which would rob many of the catarrhal inflammations of their dreaded sequelæ.

The patient was infected from a discharge, which, while gonorrheal in character and showing a few gonococci under the microscope, was yet not as inflammatory in character as is usually the case. I also used protargol in two cases of ophthalmia neonatorum and made careful observations of the same, and obtained good results. In granular conjunctivitis, I used the stronger 10 to 20 per cent., and while it seemed to lessen the discharge, yet the granulations were not changed in caliber. In serpiginous ulcers of the cornea, I did not get as good results as I expected; ordinary ulcers of the cornea did not show any greater response to its curative properties than to nitrate of silver. In dacryocystitis, I used it frequently, and it seemed in such cases to be of especial value, stopping the secretions, but not curing them. Its use gives no pain; only a slight burning is felt for a few minutes after its application, which makes it valuable where one is compelled to use it on children.

What led to my investigating its germicidal properties was the claim made for it that it had more penetrative power than the other silver salts, and therefore was of greater value in blenorrheal cases.

My assistant, Dr. Rivas, made some experiments in the pathological laboratory of the Medico-Chirurgical College, January 1899, and his report is as follows:

Transfer.	5 per cent.	10 per cent.	25 per cent.
Immediate.	300 colonies.	No growth.	No growth.
5 minutes.	Many colonies.	17 molds.	No growth.
15 minutes.	124 colonies.	No growth.	No growth.
30 minutes.	21 colonies.	No growth.	11 molds.
60 minutes.	2 colonies.	No growth.	No growth.

50 per cent., no growth.

Control, too many colonies to count.

The following experiments were made by Dr. W. Wayne Babcock:

1. *Method.*—A portion from an old agar-agar culture of bacillus anthracis was mixed in a 10 per cent. aqueous protargol solution, and after 1, 5 and 10 minutes, loopfuls of the mixture were introduced into melted agar-agar, pleated out in dishes and placed in the incubator (37 C.) for about 48 hours.

Per cent. protargol.	Time of exposure.	Number of colonies.
10 per cent.	1 minute.	22 (chiefly minute.)
10 per cent.	5 minutes.	6 (chiefly minute.)
10 per cent.	10 minutes.	None.

Control made on agar-agar slant showed luxuriant growth after twenty-four hours' incubation.

Several drops of 5 per cent. protargol solution in which anthrax bacilli had been introduced 85 minutes before were spread upon an agar-agar slant and incubated about 48 hours without apparent growth.

These experiments indicate that protargol in 10 per cent. solution has a distinct germicidal effect upon anthrax bacilli and their resistent spores after ten minutes' exposure.

2. Similar experiments with bacilli of diphtheria. There was no growth after 1 minute exposure to 10 per cent. protargol solution; but these experiments are rejected from lack of satisfactory control.

The remaining experiments were all conducted after the method suggested by D. W. Hill. (Public Health Reports, xxiv.) The method is to smear the lower end of a sterile rod with a thin coating of a pure culture of the micro-organism.

After permitting the bacterial coating to spontaneously dry it is introduced for a measured time in the antiseptic solution, washed in sterile broth to remove the excess of the antiseptic and finally incubated in a tube of sterile broth for two days at about 37 C.

3. Virulent anthrax.—Agar-agar slant culture, 24 hours old smeared upon the ends of glass rods.

Protargol.	Time of exposure.	Growth.
1 per cent.	½ minute.	+
1 per cent.	1 minute.	+
1 per cent.	2 minutes.	Sterile.
5 per cent.	½ minute.	+
5 per cent.	2 minutes.	Sterile.

Control, growth.

A tube for washing after exposure to 1 per cent. protargol solution showed a growth.

4. Similar experiments with 48-hours anthrax culture—agar-agar slant.

Protargol.	Time of exposure.	Growth.
1 per cent.	1 minute.	+
1 per cent.	3 minutes.	+
1 per cent.	5 minutes.	+
1 per cent.	5 minutes.	+
1 per cent.	10 minutes.	+

Control, +.

Broth used for washing the antiseptic solution from rods.

Per cent.	Time.	Growth.
1	1 minute.	+
1	3 minutes.	—Sterile.
1	5 minutes.	—
1	10 minutes.	—

It is to be expcted that the 48-hours culture would show greater resistance from the presence of many spores.

5. Bacillus typhosus.—Rods smeared from slant culture upon agar-agar:

Per cent.	Time of exposure.	Growth.
1	½ minute	+
1	1 minute	+
1	5 minutes	+
5	5 minutes	Sterile.

Control, growth, wash broth; no growth.

6. Staphylococcus aureus from slant culture upon agar-agar smeared upon glass rods. Incubated in broth about 48 hours.

Per cent.	Exposure.	Growth.
1	2 minutes.	+
1	5 minutes.	—Sterile.
1	5 minutes.	+
1	10 minutes.	+
5	½ minute.	+
5	2 minutes.	+
5	5 minutes.	+
5	5 minutes.	Sterile.

Wash broth remains sterile.

The discrepancies in the results of the experiments with staphylococci suggested that protargol solutions might be lacking in penetrative power and thus unable to rapidly sterilize the deeper layers of the thicker smears. Further experiments were undertaken to determine this point, but have not as yet given results that warrant report.

7. Diphtheric broth-cultures smeared upon glass rods.—As the particles of diphtheric cultures are readily washed from the glass rods it is thought that these results are more liable to error than the previous ones.

Per cent.	Exposure.	Growth.
1	½ minute.	Sterile.
1	5 minutes.	Sterile.
5	½ minute.	Sterile.

Control, +; wash broth, sterile.

Dr. G. E. de Schweinitz, Philadelphia—I have listened with the greatest interest to Dr. Hotz's enthusiastic endorsement and to Dr. Fox's equally enthusiastic remarks. I have used protargol a great deal within the last few months and have been very much impressed with its uncertainty. I have seen it do just such marvelous things as Dr. Hotz described and have seen it just as ignominously fail, so I have begun to feel that perhaps we have been too enthusiastic over this new silver salt. My own experience is that protargol is far more agreeable, of course, than nitrate of silver, but can do nothing that the nitrate will not do and the latter frequently does many things that protargol will not do. I have not used it quite as strong as Dr. Hotz recommends, but used it in the same way. I began with a 10 per cent. solution and have gone as high has a 15 per cent solution.

In one particular my experience corresponds with Dr. Holtz's, and that is that when a croupous membrane forms and nitrate of silver would do harm, protargol does not; but I regret to say also I have not seen it do good in such cases. I have great respect for the remedy and use it daily, but it is uncertain.

Dr. Casey A. Wood, Chicago—The reason that I suggested that this remedy should be taken up for discussion this year, was because I think I was one of the first to use it in the part of the country where I live and I have found that I am not able to get those universally good results from it that men elsewhere have been reporting. My experience has been very much the same as that of Dr. de Schweinitz, and I was afraid that I should be the only one here to sound a discordant note in the chorus of praise that has been raised. I think perhaps we have been using nitrate of silver in many cases where it has done harm and where possibly cleansing and the use of mild remedies would have brought about a cure in any event. I must say that in some cases of corneal ulcer where massage was used with it, it brought about fairly good results, but I am not able to bring myself to think it is better than nitrate of silver and some other agents which we have known for a good while.

Dr. T. Y. Sutphen, Newark, N. J.—I have recently seen a case of sloughing ulcer of the cornea. This tissue was entensively infiltrated, while the anterior chamber was nearly full of pus. In this case I felt sure the man would lose his vision. To my delight the trouble began to mend directly after beginning the use of protargol in conjunction with hot water. I attribute the benefit in a great measure to the drug. Argonin I prefer in purulent conjunctivitis. With these remedies I have lost many of my fears concerning a favorable result in severe corneal and conjunctival cases.

Dr. C. F. Clark, Columbus—I want to agree with Drs. Wood and de Schweinitz in their judgment of protargol, for my experience has been quite similar. Excellent results have been obtained in dacryocystitis. It has failed so utterly in other cases where it should have done good that I at first thought I had not a fair sample of the drug, but at the same time another case of keratitis treated from the same sample would do well. I have had better results with antinosine in similar cases.

Dr. Frank C. Todd, Minneapolis—I would like to ask Dr. Hotz if this drug has been used for the prevention of ophthalmia neonatorum as we use nitrate of silver, and if so in what strength?

Dr. Edward Jackson, Denver—I have used protargol a good deal and on the whole I think I would rank it as highly as the solution of nitrate of silver. As a last resort or final dependance I would prefer the nitrate; but the protargol seems so much more generally applicable to a large number of cases that I think on the whole it is probably quite as useful. For the great mass of cases it is certainly very much less irritant than the silver nitrate. But I arose principally to mention the exceptions. I had used it many months without meeting with an exception when I came across a case of dacryocystitis in which I injected it into the sac, after having given the patient a 5 per cent. solution. There was free drainage at the time. The patient complained very bitterly of the suffering it caused, and on subsequent trials this was renewed. He even preferred the passage of a large Theobold probe to the use of protargol. The eyes the next day showed an amount of redness and general irritability that they had not shown at all previously. Even a 1 per cent. solution produced this condition. Since then I have met another patient who made the same complaint on its application. It must be rare to meet with such cases, but they must be looked out for.

Dr. F. W. Southard, San Francisco—I desire to give my testimony in favor of protargol. I have used it for nearly two years in my clinic and have come to place great reliance upon it. I believe, however, that the method of using it is of importance. The eye-ball and the ocular surface of the lids should be thoroughly but gently irrigated with bichlorid solution, 1-8000 or formalin .25 per cent. before applying the drug. It is true I have had failures, but on the whole I feel that it is a most useful drug and shall for that reason continue its use unless I find that my cases do not do as well as by the older methods.

Dr. Frank Allport, Chicago—My experience with protargol has been variable. In view of its enthusiastic endorsement by reputable observers from all parts of the world, I commenced its use with full faith as to its efficacy. I saw many speedy and favorable results, but I also encountered some failures. I do not regard it as highly now as I did at first. It certainly possesses some advantages over nitrate of silver, which have been thoroughly described by the gentlemen who have preceded me; but I have had cases like those mentioned by Dr. Jackson, where even a weak solution produced considerable pain, notwithstanding the fact of its recommendation as a painless application. I remember one case where an injection of a 10 per cent. solution into the lachrymal sac practically disabled the patient all day. I have used as high as a 50 per cent. solution occasionally, and a 25 per cent. solution frequently, but it seems to me that I obtain about as good results with a 2 or a 5 per cent. solution as from the stronger ones. I think the principal point in favor of protargol is its easy application, and the freedom with which one may use it; but I can hardly say that I have seen cases where it has accomplished results superior to what might have been accomplished by the old nitrate of silver properly applied, unless it may be in apparent affections of the lachrymal sac, where it appears to possess especial beneficial qualities. In using protargol I evert the lid and cleanse it with sterile water and cotton, and believe that this procedure materially enhances its value. Another point which makes protargol a remedy of great service to ophthalmologists is the fact that it can be freely given to patients to use at home, which surely is in striking contrast with nitrate of silver.

Dr. Leartus Connor, Detroit—If the reports of scientific investigations respecting the germicidal powers of this drug be correct, under the same conditions its application should produce the same results with a preparation that is equally reliable. Now, I suspect that they are correct and I have no reason to doubt it, but there is reason to doubt whether different samples of the drug are of equal value, otherwise I can not understand why for two and a half years I should have failed to accomplish under the same conditions the same results the other gentlemen have. Of course it is not to be supposed that this agent if applied with mucus over the surface will always penetrate through that and be adequate to kill the germs beneath it, and so its application must be made with care, but as to the strength of the solution, for myself, I think it doesn't matter except that if you use a weak solution you must use more of it, in other words there must be enough of the powder to carry the charge and there must be enough of the germicide to kill the germs. I was led to use this drug through the recommendation of an ophthalmologic friend, in whom I have a great deal of confidence, some three years ago. He told me his results and having enough confidence in him to repeat his observations I found he was quite correct. A year and a half later I met him again and asked if he were using it still and he said, "No, it is no good." I said, "Now that is funny, I have done just as you told me and with just the results you told me, and it has been the delight of my life," for I have to treat a large number of cases of purulent ophthalmia in the children's hospital and they used to be a source of very great anxiety, while with this agent not a single eye has been lost. In the gonorrheal cases in the adult my experience has corresponded exactly with that of Dr. Hotz. I do not approach these cases with the fear and trembling I used to with the nitrate of silver, but I think this should be borne in mind, that the constant cleanliness which we should always employ is just as necessary with this drug as with the nitrate of silver.

Dr. A. D. McConachie, Baltimore—I would like to ask Dr. Hotz if he has had any experience with the use of protargol in acute trachoma. The reason I ask it is because of some experience of my own. I contracted an acute trachoma in one eye, probably in dispensary work at the hospital. Nitrate of silver was used and showed marked improvement for one day, with a relapse the next, and this condition went on with intermissions for a week, and then protargol was used. I can testify to its non-irritating properties, as it was simply no worse than boracic acid or cocain drops, but it did not produce an arrest of the discharge. Prior to that time I had used it a good deal in hospital practice, and I remember one case distinctly of double purulent ophthalmia where the gonococcus of Neisser was found, in which I used in one eye the protargol solution and in the other simple mechanical sterilization with the ordinary plasmin solution thoroughly applied every hour. One eye got well quite as quickly as the other. That may be coincidence, but we continued to use it at the hospital and my confrères there, as well as myself, returned to the use of the old stand-by, nitrate of silver. Time and again we have had to give up the use of protargol and go back to the nitrate of silver.

Dr. Albert E. Bulson, Jr., Fort Wayne—With reference to the use of protargol in the treatment of trachoma I wish to say that my experience has been on the whole satisfactory. In an epidemic of acute trachoma occurring in one of our orphan asylums I found protargol produced less discomfort than applications of silver nitrate and many times proved just as efficient. In some instances, however, the protargol applications did not seem to produce good results, and the substitution of silver nitrate was followed by improvement. The protargol was first used in 20 per cent. solution, but I soon found that in the majority of instances a 30 per cent. solution proved most efficacious. I never saw any unfavorable action on the cornea. In the treatment of ophthalmia neonatorum I have the utmost faith in the daily applications of 20 per cent. solution of protargol and prefer this treatment to any other. To my mind protargol certainly has a distinct therapeutic value, and in the majority of instances can be substituted for the more active and irritating nitrate of silver.

Dr. E. E. Holt, Portland, Me.—About a year ago I had some bad cases of purulent conjunctivitis that had been treated by good men, using nitrate of silver. It occurred to me in continuing the treatment usually carried out in such cases, that these eyes were going to be blind, if not helped at once, and I began to douche the eyes with the Davidson syringe, leaving off all local treatment, except to keep the water flowing in the cul-de-sac night and day. In one case where the swelling was so great that I expected to do a canthotomy the next morning, I found, however, after the douching over night that the swelling was very much reduced, and the eyes went on to a complete recovery without the application of any drug. I noticed that all the gentlemen prefaced their remarks on the use of protargol by stating the need of absolute cleanliness, and Dr. McConachie's case shows this is quite as effective as any remedies used. I think a complete continuous washing out of the conjunctival cul-de-sac will give good results. I have never lost a case since I began this treatment.

Dr. G. L. Hiers, Savannah—I wish to add my testimony to what has already been said in favor of protargol. I have been using it quite freely for eighteen months past and with excellent results. I make it a point, as several of the gentlemen have emphasized, to insist upon absolute cleanliness and I give my patient a weak solution, about 5 per cent. to instill into the eye every three hours. I see the patient once or twice a day, as may be indicated, and make application of a 10 to 15 per cent. solution and follow it with the use of the ice compress. So far my results have been phenomenally good.

In dacryocystitis my experience has been limited, but results were good. In trachoma I never fail to write for protargol and in chronic cases I first squeeze them with Knapp's roller forceps and then use protargol. I have had excellent results.

Dr. Hotz—Let me first answer the questions. I was asked: What is my experience with protargol in acute trachoma? I have not used it? As to the question whether it has been used as a preventive in lying-in-hospitals I think it has recently been tried in lieu of argentum nitrate.

Now, Mr. Chairman, I took it for granted that before treating an eye, or rather before making an application to the conjunctiva of an eye showing a purulent discharge, the lids would be cleansed; and it never occurred to me that the remark in my paper where I said the eye did not need to be washed out, would be interpreted to mean that I did not clean the eye before making an application; but it seems it was so understood by several of the speakers, as they laid particular stress upon the necessity of cleansing the eyes before treatment. My remark had reference to the washing out of the eye after the application of protargol. As you know we use water or salt water, to precipitate the superfluous nitrate of silver after its use on the conjunctiva. If the gentlemen who have spoken of treating these cases by simply observing absolute cleanliness say that they instruct the nurse to insert the nozzle of the syringe under the lids and believe that they will accomplish absolute cleansing of the eyes, they are mistaken. I have never seen an eye which did not show a good deal of mucopurulent material under the lids when they were everted after such irrigation. Some cases we know get well without treatment and others do not, but because a case gets well by doing nothing I do not think it proves that when an application is made in another case, that application is of no value. Now I have not presented this paper because nitrate of silver is not a good and excellent remedy. I have always used and recommended it; but if, as all the gentlemen admit, this new remedy is equally efficient and more pleasant to the patient I do not see why we should adhere to an old remedy and not give the patient the benefit of the more agreeable treatment. I wish to say also that the observations in my paper do not represent my whole clinical experience with this remedy. When I began to use it two years ago I at first had poor results and hence did not start in as an enthusiast for protargol; but my observations lead to the conclusion that I could attribute my failures in the first place to the use of too mild solutions. In using nitrate of silver we consider a 5 per cent. solution very strong, and so I began with a 5 per cent. solution of protargol, which did not accomplish any good. I then tried stronger solutions but did not see any prompt and positive results, until I used 20 per cent. I can only repeat that by starting with a 20 per cent. solution at once and using it in such a way that it comes in close and thorough contact with the affected parts you will accomplish as much good as with the nitrate of silver, and as the application of protargol is not attended by the severe pain and the violent irritation usually caused by argentum nitrate, I am sure we have good and sufficient reasons to substitute protargol for the same.

A SIMPLE OPERATION FOR DIVERGENT STRABISMUS.*

L. WEBSTER FOX, A.M., M.D.
PHILADELPHIA.

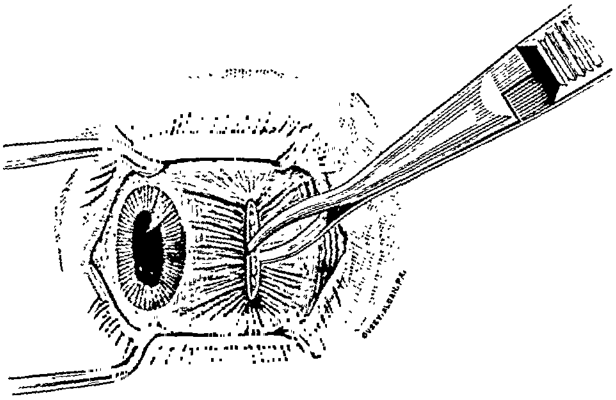
All ophthalmic surgeons have been more or less disappointed in the results obtained from the various operations now in vogue for this deformity. The fact that so many operations have been devised for its correction speaks for the failure of the various methods. Having had unusual opportunities for putting the accepted methods to a test and noting the difficulties and many failures ordinarily experienced, I have for the last eight years followed a method which has been more uniformly successful in my hands than any other.

---

*Presented to the Section on Ophthalmology, at the Fifty-first Annual Meeting of the American Medical Association, held at Atlantic City, N. J., June 5-8, 1900.

I shall not attempt to describe the various operations which might be called the standard methods; that would be too tedious to a body of gentlemen who have had such varied experiences as the majority of the members. This operation, which has given me such good results, has been developed on lines laid down by De Wecker, Grandclement and Panas. It appeals to me as being much simpler than either of the above. It is in cases where the deviation is five millimeters and upward that this operation is best adapted.

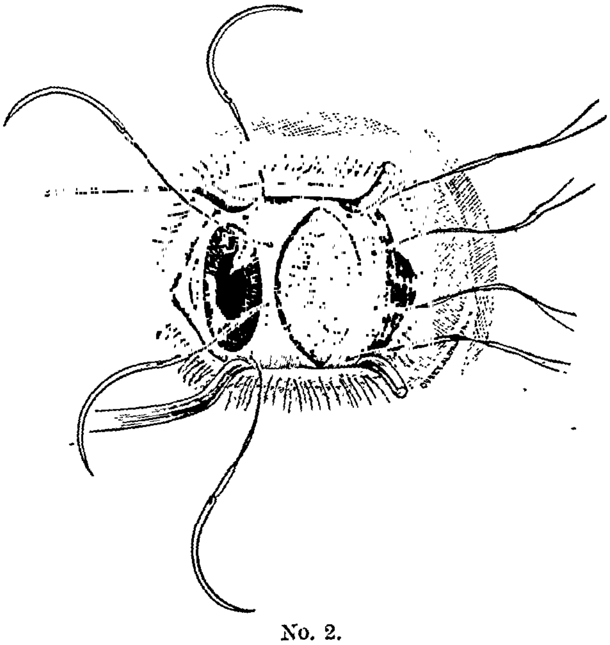
The operation is divided into three parts and is performed under cocain: 1, tenotomy of both external recti muscles and stretching of conjunctiva and Tenon's capsule; 2, making the elliptic opening either on one eye or both; 3, suturing this opening.



No. 1.

The details of the operation are carried out as follows:

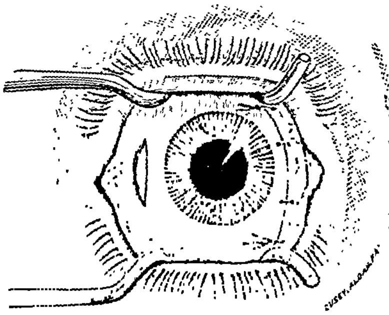
1. Tenotomy of both external recti muscles, making an opening through the conjunctiva, over the insertion of the tendons. I then stretch Tenon's capsule until the cornea is well into the inner canthus—this is done on both eyes. Panas' method is to insert the hook under the muscle and apply pronounced traction, at the same time burying the cornea in the outer or inner canthus. The operation is performed under ether or chloroform, while in this method cocain is only used. The stretching of Tenon's capsule is an important part of the operation. My method is as follows: The strabismus hook, which is a large one, flat on its side, is inserted in the opened conjunctiva and Tenon's capsule and with considerable traction all the tissues are stretched inward until the cornea is buried in the inner canthus. The stretching of the upper tissue has, as can be readily understood, a tendency to rotate the eyeball to a certain degree and leave the conjunctiva and Tenon's capsule intact below; to equalize the stretching, the point of the hook is reversed, and the lower conjunctiva and capsule stretched. In Panas' method the hook being placed under the external or internal muscle prevents rotation of the eyeball.



No. 2.

2. With the retractor forceps I grasp the conjunctiva vertically, midway between the cornea and caruncle and directly over the internal muscle, and draw upward the conjunctiva and as much of Tenon's capsule as I can. I raise the forceps two or three times to take up as much of the redundant tissue as my judgment dictates, and by this means one apparently is always successful in separating conjunctiva and overlying tissue from the muscle, if it be still present; then with curved scissors I cut with one long sweep the upraised conjunctiva and capsule close to the eyeball, making an elliptic opening, exposing, at times, the attenuated muscle, and, if no muscle be present, then the clear sclerotic.

This opening now extends in a vertical direction, beginning below the lower level of the cornea to a point above the same, its width over the muscle is about one full centimeter at its greatest diameter. The conjunctiva is then separated around this elliptic wound from its subconjunctival tissues at all points, even around the cornea if possible.



No. 3.

3. The elliptic opening is brought together with four sutures; the upper suture is inserted through conjunctiva and Tenon's capsule and across under conjunctiva and Tenon's capsule midway between the insertion of the superior rectus muscle and the margin of the cornea; a similar suture is passed through the lower margin of the conjunctiva and brought out midway between the insertion of the inferior muscle and the margin of the cornea; this thread is then tied and in like manner the upper thread; two more sutures are passed through the margin of the lips of the wound and united.

This constitutes the details of the operation. The object of the operator should be to produce one to four millimeters of convergence, which disappears during cicatrization. When the defect is not more than two or three millimeters I have performed an external tenotomy on both and stretched Tenon's capsule, with excellent results, without taking out the elliptic section, especially in those cases where the eyes could be held by the patient at fixed convergence at ten inches.

While this operation is similar in many details to that of De Wecker, Knapp, Snellen, Gruening and Grandclement, yet I am sure its simplicity has much to commend it, and the results obtained in my hands make it preferable to any single one of the above-mentioned methods.

NOTE.—I refer the reader to Dr. St. John Roosa's article in *The Postgraduate*, November, 1899.

1304 Walnut Street.

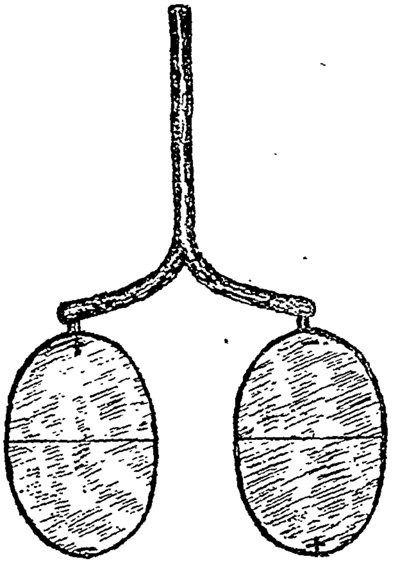
HOW TO PLACE LENSES BEFORE THE EYES SO THAT DISTANCE OF THEIR RESPECTIVE ANTERIOR FOCI SHALL BE THE SAME.*

MARK D. STEVENSON, M.D.
AKRON, OHIO.

Not every ophthalmologist seems to realize the extreme importance of having the anterior focus of each eye at exactly the same distance, and many who try to obtain this fail because of the improper methods used.

If the anterior focal points are not exactly at the same place the ciliary muscles in their ceaseless efforts to find a position of rest will be under a constant seesaw. Every ophthalmologist finds cases in which comfort and good vision can be obtained for each eye separately, yet when the patient looks with both eyes, he complains of discomfort and dizziness and of not being able to see clearly. The problem is how to remedy this.

Many patients with glasses have the same visual acuity in each eye. After refracting such cases, and while they view distant test-types with both eyes, I take a plus and minus sphere of .25 diopter strength and place one before each eye, wait a few moments, when I quickly interchange them. If the patient has any choice it shows me that I must raise the correction of one or lower that of the other, or do both.



If, however, the acuity of vision of one eye is the slightest amount better that that of the other, I take the same lenses, and, placing first one and then the other before the same eye, find which is better, and repeat the same process before the other eye. If a change is needed, the patient will accept a plus before one eye and a minus before the other; this method also indicates in what manner to proceed.

For the sake of convenience, I have combined four lenses, as shown in accompanying diagram. In the first test I hold the two lower lenses in front of the eyes a few moments, and then quickly lower the upper two into position.

In the second test, and in fitting for near, I use one side of the combination, putting first one and then the other before the same eye. It is not to be forgotten, in making the last test if the eyes are not completely under the effect of a cycloplegic, the patient will often choose a minus glass for both eyes, because there is a tendency to accommodate.

In all cases, after having finished these tests, always try stronger convex or weaker concave glasses of the same amount on both eyes.

In presbyopia the amount to be added to the refraction for distance may differ in the two eyes on account of differences in the progress of sclerosis of the lenses and the consequent changes in the ciliary muscles. The common method of fitting presbyopia is to add the same amount to the distant refraction of each eye, and to decide if the desired location of the near test-type is the same for each eye separately. This method can not be relied on, because, not being able to appreciate slight differences in the distance from the eyes to the test-card, and making a probable mistake in each eye, the patient claims that both see better at, say a distance of thirteen inches, whereas, in reality, the one is focused for twelve inches and the other for fourteen inches. It may be supposed that the eyes are now focused at the same distance; but they are not, until you have made a difference in the strength of the lenses equal to 40/12 diopters minus 40/14 diopters, or more than .38 diopters.

By virtue of the fact that the patient is not able to distinguish slight differences in the distance from the test-card to the eyes, you can not get a good result while the test-card is held at a fixed distance.

I increase the spherical strength of lenses to what I think will be necessary to make the anterior focus at the proper distance from the patient's face. Then I have him hold the test-card at the place of best and easiest vision, and use the last method spoken of for distance. If he choses a plus glass on one side and a minus glass on the other, I proceed as before mentioned. If, however, he chooses plus in front of both, I have him hold the card a little farther off, and if minus, a little closer to his eyes, and then repeat the process. When he can not choose between the plus and minus glasses the eyes are balanced.

DISCUSSION.

DR. JAMES THORINGTON, Philadelphia—In making this final test in estimating the refraction I think it is always well that we proceed slowly with the previous steps, for that is the way to perceive any decided benefit after we have proceeded carefully in testing each eye separately. There are two points that ought to have careful consideration—the first is to have the lenses used in testing the vision for distance placed very close to the eye, and the next is to have the lenses properly centered before the eye. To do this you have to ignore the trial frame as a rule, because so many of them are not adjusted to the patient's face. I often use the trial frame attached to the Risley phorometer and having tested each eye separately and then testing the eyes together in the way the doctor suggests I find there is very little advantage and that very few patients will appreciate the +.25D., but will quite frequently accept the —.25D. This is decidedly the case with myopics. Then there is this danger, that if you do not place Dr. Stevenson's instrument close to the lenses you get something of a periscopic effect. In presbyopia I find that a certain percentage can not always differentiate 0.25 plus or minus, with any degree of certainty; I therefore hesitate to embarrass them by asking for a positive answer. Patients come to us to have their glasses selected by us, and depend on our judgment; if they must decide for themselves then they think they might just as well visit an optician.

---

*Presented to the Section on Ophthalmology, at the Fifty-first Annual Meeting of the American Medical Association, held at Atlantic City, N. J., June 5-8, 1900.

Dr. Mark D. Stevenson, Akron, Ohio—As a rule patients very quickly decide which lenses they prefer, and I consider that lenses of .25 diopter strength are sufficiently strong and I often use lenses of .12 diopter. When the patient is not under the effect of a cycloplegic and there is a tendency to accommodate, if the vision of the two eyes is unequal the patient would be apt to choose a minus glass before the better eye, but when the vision in both eyes is equal there should be no choice for the purpose of accommodating. I have failed to find any reference to this method of fitting in literature.

Dr. J. A. Lippincott, Pittsburgh—I would like to say that I think this little apparatus a very convenient one and it may serve a useful purpose. I have used the same principle for a great many years by simply holding a +.25 and —.25 in either hand and transferring them during the examination. This apparatus will enable us to save time and trouble and I think there is no question of the value of making this test with both eyes open after you have completed the test with both eyes separately.

KERATITIS BULLOSA, WITH REPORT OF CASE.*

ELLET O. SISSON, M.D.
Member of the International Congress of Ophthalmologists.
KEOKUK, IOWA.

My reason for reporting this case is because it is one of great rarity. Statistics go to show that keratitis bullosa is the least frequent of all corneal troubles. It is fortunate for both the physician and the patient that such is the case, for it is one of the most painful affections that the eye is liable to, and in the majority of cases baffles all therapeutic and surgical measures adopted for its relief. The disease occurs in the eyes, the cornea of which is more or less clouded and sensitive, or in eyes with a large corneal cicatrix, or eyes which have been rendered blind by iridocyclitis or by increase of tension.

Jansen[1] describes a primary form occurring as the result of an abrasion of the cornea by the finger-nail, a twig or some such object. But the majority of cases are secondary and occur as the result of the diseased processes above mentioned. This disease is characterized by the formation on the cornea of large tremulous bullæ which last for several days before they rupture. They are not tightly distended, but form a lax, tremulous, somewhat dependent sac. After their rupture the lax anterior wall still lies upon the cornea, and can readily be made out by the way in which it can be displaced by the movements of the lids. In all cases the bullæ show a great tendency to take on frequent recurrences, in each of which the irritative symptoms set in anew. Violent symptoms of irritation, such as ciliary injection, lachrymation, photophobia, and more especially great pain, are usually present during the development of the bullæ. These doubtless are caused by the pulling upon the corneal nerves which pass into the epithelium, and which, in the process of formation of bullæ are first stretched and finally torn in two.

The irritative symptoms ordinarily disappear with the rupture of the bullæ. The bullæ appear to have a double origin. 1. According to Fuchs, the lymphatic stasis of glaucomatous eyes produces an interstitial edema of the epithelium, which tends to the production of vesicles, etc. 2. The continual irritation of the corneal epithelium alters the nutrition of the cells. Above all, the cells of the middle layer are transformed into clear vesicles, which in places acquire a very large size. The cellular membranes of these larger vesicles are destroyed, and in this manner a lacuna is produced, which is often rather large, and becomes more and more distended; such a vesicle is covered by epithelium that separates it also from Bowman's membrane.

The first mode of formation produces vesicles covered by epithelium and resting upon Bowman's membrane; the second method furnishes the intraepithelial vesicles. Vesicles which lie in the substance of the corneal membrane have also been described; they are said to be developed underneath Bowman's membrane. This point, however, merits further research.

The prognosis is so far unfavorable in that the disease often recurs, on which account the affected eye, besides being useless for purposes of vision, is the source of constant discomfort to the patient. The treatment should aim at relieving the condition of irritation produced by the eruption of the bullæ, and at preventing the recurrences. Sometimes we do not put a stop to the recurrences until we have improved the conditions for the nutrition of the eye by means of an iridectomy or posterior sclerotomy; we may even find ourselves compelled, as the operator was in this case, to perform enucleation of the diseased eye in order to give the patient relief.

Mrs. L. presented herself at my office July 12, 1898. She was of German descent, about 50 years of age; had always had good health; was the mother of several children. Subjective symptoms: Patient said that she had had the present eye trouble for about a year; had been better at intervals; no history of any injury; was suffering great pain at this time. An examination showed the presence of a large tremulous bulla measuring 4 by 5 mm., situated nearly in the center of the cornea. The remaining portion of the cornea was clear, anterior chamber of normal depth and T. normal. There was ciliary injection, lachrymation and some photophobia. Further examination revealed the presence of a cataract and complete posterior synechia of the iris; V.=0. This condition was undoubtedly the cause of the keratitis.

I adopted the usual mode of treatment, namely, opening the bullæ and touching the raw spot with nitrate of silver solution. I also used a strong solution of atropia, with the hope that I might break up some of the adhesions of the iris, and thus improve the nutrition of the parts. But I soon found this to be fruitless, and had to limit the treatment to simply opening the bullæ, which would give the patient relief for the time being, and perhaps a night's rest, but the next day another large bulla would develop on the same spot and the patient would again suffer excruciating pain. She would beg me to remove the eye, saying that she could not stand it. This I was loath to do, as the eye ball was perfect and not in the least unsightly, and most of the time there was not even congestion of the bulbar conjunctiva.

On August 24 I determined on making an iridectomy. Cocainizing the eye, I made the usual incision with a keratome, but I experienced considerable difficulty in dragging forth the iris; as before stated, it was firmly bound down by adhesions, which were hard to loosen, the iris tearing first. But I succeeded in making a fair-sized coloboma, dressed the eye as usual in such cases, and awaited results. The case progressed nicely, patient suffering no pain, and there was no sign of a return of the bulla after several days had elapsed. I began to feel quite hopeful of success, and had arranged to dismiss the patient from the hospital, when, beh[illegible] one morning when I removed [illegible] ge prepa[illegible] to [illegible] the eye, I disc[illegible] [illegible]tely f [illegible] same spot, the only difference between it and the previous ones being that it was not quite so large. This was my only consolation, and I hoped that after the eye had completely recovered from the operation they might disappear altogether.

*Presented to the Section on Ophthalmology, at the Fifty-first Annual Meeting of the American Medical Association, held at Atlantic City, N. J., June 5-8, 1900.

[1] Arch. d'Ophthal., April, 1898.

For several weeks following the patient suffered less pain than previously, the bullæ not being as large nor lasting as long, but the condition gradually became worse, until on October 9, 1898, I was forced to enucleate the eye. I would much rather have performed evisceration in this case, inserting a glass ball after the manner of J. Webster Fox or the aluminum one of D. Bryant, but the patient was not suitable for such an operation, being very intractable, which is not desirable for such delicate work, where complete submission and assistance on the part of your patient enables you to obtain a much better result. She made an uneventful recovery after the operation, and, after fitting her with a glass eye, she was one of the happiest women imaginable.

CHEMICAL FACTORS IN INTERSTITIAL GINGIVITIS.*

W. L. BAUM, M.D.
CHICAGO.

In dealing with the influence of any etiologic factors, these factors must be considered in connection with the organism on which they act—the latter in its constitutional aspects and in regard to its condition at the time the chemical factor begins its action. The local condition of the parts affected must likewise be taken into consideration. As the gums at times take upon themselves the function of excretion, they are peculiarly apt to be affected by chemical action. Prominent among the agents which produce effects on the gum and the other transitory structures are the alteratives and tonics. Arsenic, gold, iodin, iron, mercury, brass, lead, copper and phosphorus all produce, by their excretion through the gums, conditions of edema, which are predisposing factors to interstitial gingivitis. Arsenic, gold, iron, phosphorus and mercury all set up an inflammatory condition. Among the vegetable alteratives having a like action; colchicum, guaiac, salicylic acid, sarsaparilla and pilocarpin are also factors to be considered. It must be remembered also, that these alteratives and tonics, through the production of edema, furnish a culture-medium for microbes. Exceptional instances of the influence of drugs on the gums are found among the anthelmintics, cathartics, diaphoretics, diuretics, emetics and expectorants. Instances are also found among the narcotics, rather from a secondary action than from the immediate consequence. Musk, opium, hyoscyamus, valerian, veratrum, acetanilid, phenacetin, phytolacca and phenocoll, all exercise an influence as either a predisposing or an exciting factor, or both. The bromids, as might be expected, exercise a decided influence in this direction; indeed, the condition for bromidism resembles, so far as its marked symptoms are concerned, very decidedly the condition produced by mercury. The same is true, though less frequently, of antipyrin, chloral hydrate, chloralamid and chloralose. The conditions produced by mercury, gold, the iodids, the bromids, phosphorus, arsenic and antimony are well known. The vegetable drugs are much less frequently taken into consideration, and the same is true of the coal-tar compounds. The key to the effects of any drug in this direction is to be found in the untoward effect of the drug; as Kiernan observes, the most potent remedies are most fertile in untoward effects. A drug of potent physiologic action must of necessity try more severely than an inert drug, inherited and acquired deficiences of constitution. The excessive strain on inhibitions weakened by acquired or inherited taint, gives an undue sway to inhibited centers. The action, therefore, of drugs, as shown in the untoward effects, reveals the weakest point in the organism, the point at which drugs are excreted, and also the glandular structures for which they have a predilection. It should be remembered, also, that alteratives, narcotics and tonics exercise an influence over that part of the nervous system which presides over growth and repair. Such an influence may either check or aggravate the processes of growth and repair.

The histologic appearance of the structure affected in interstitial gingivitis, secondary to mercury, according to the work of Talbot, showed that the epithelial lining of the gums did not present pathologic changes, but appeared normal in every respect. Connective tissue below the gum-epithelium—the tissue analogous to the papillary layer of the derma and the derma proper—presented unmistakable evidences of a mild inflammatory process. There occurred in this connective tissue round-cell infiltration, generally moderate, but in some places quite dense. This cellular infiltration extended from below—where it was densest—upward into the papillary layer. The densest cellular infiltration usually occurred around the vessels.

Under high magnification, the cellular infiltration was found to consist of polymorphonuclear leucocytes, plasma cells and plasma-mast cells, the latter with coarse basophilic granulations.

In some places were seen between the round cells, short, broad, fusiform cells, the protoplasm of which took quite well basic methyl blue. These cells resemble fibroblasts very much and appear to be derivations of the plasma cells. No bacteria were found either in the areas of cellular infiltration—inflammatory areas—or elsewhere. In these cases it is obvious that there had occurred a mild inflammation of the gums—gingivitis. While this could not be seen with the naked eye, microscopic examination demonstrated histologic features of an inflammatory process. The absence of bacteria justified the belief that this inflammation was not of microbic origin, but due to mercury, which, by its well-known chemotactic influence, produced the histologic changes of an inflammation.

A further study of Talbot's specimens shows that the irritation chemotactically produced results in an inflammatory reaction upon the intima of the vessels, setting up an endarteritis which, by the thickening of the intima and proliferation of endothelial cells, ends in occlusion of the vessels—endarteritis obliterans—thus by cutting off the nutrition, producing an anemic infarct, which either undergoes absorption or becomes necrotic. The bacteriologic invasion is always secondary to this process.

What is true of mercury is also true of other alteratives.

---

A. T. Still, M. D., the founder of the osteopathic cult, in the *Journal of Osteopathy* for July, delivers himself of the following lucid sentence: "All bones and softer parts must obtain all matter entering their form and kind." This reminds one of the cheerful and enlightening conundrum: "Why does a mouse spin?"—*Cleveland Journal of Medicine*, July.

THE CONSTITUTIONAL TREATMENT OF INTERSTITIAL GINGIVITIS.*

J. H. SALISBURY, A.M., M.D.
Assistant Professor of Medicine and of Chemistry, Rush Medical College; Professor of Medicine, Chicago Clinical School.
CHICAGO.

At no previous period in the history of medicine has the importance of a thorough acquaintance with the human system as a whole and of the interdependence of the various organs been so well recognized as to-day. Since local diseases are scarcely ever uninfluenced by the systemic condition, it becomes important to consider their constitutional as well as their local treatment.

Interstitial gingivitis is a disease comparatively unknown to the general practitioner, but it is to be hoped that the recent investigations which have thrown such a clear light upon its nature and effects will arouse the interest of the profession, so that its treatment will be undertaken at a stage when there is hope of recovery without permanent injury to the gums or teeth and before serious affection of other organs arise from it.**

Interstitial gingivitis, or so-called pyorrhea alveolaris, has been classified by Dr. Talbot[1] as due to local and constitutional causes. The constitutional causes include mercurial, lead, brass and other drug poisoning on the one hand, and autointoxication on the other. Dr. Talbot has shown that this disease has its origin in the tissues of the gum and alveolar process, and that atrophic changes precede the invasion of the tissue by micro-organisms. These primary atrophic changes are due to poisons circulating in the blood, and hence the disease falls into the large group of affections caused by autointoxication. The constitutional treatment of this disease must be governed by its etiology. Successful treatment must keep in mind the toxemia by which it is caused and endeavor as far as possible to trace the origin of the poison which is at the root of the local disease.

Autointoxication means self-poisoning, and has received a somewhat wide application, so as to include all cases of disease in which the poisons that produce the symptoms arise within the system and are not produced by recognized pathogenic organisms.

These poisons may be divided into several classes: 1. Poisons produced at all times by the ordinary metabolic activity of the tissues, which accumulate in the latter until they produce the symptoms of disease; 2, poisons produced in abnormal amount by the unnatural metabolism of certain tissues; 3, poisons produced by the metabolism of the tissues, but which are not produced at all in health; 4, poisons produced by bacteria in the intestines or other parts of the system, and which accumulate in the body in consequence of imperfect action of the eliminating organs; 5, poisons produced in abnormal quantities by bacteria in consequence of circumstances favoring bacterial activity; 6. poisons produced by bacteria which are not normally formed in the system.

In general we may divide these poisons into two classes, according to the place where they originate: 1. Those which are formed by fermentation in the stomach or intestines; 2, those which originate in improper metabolism of the tissues. According to Pœhl,[2] these two can be distinguished by analysis of the urine. The substances arising from fermentation in the intestines include several aromatic substances which are excreted as conjugated sulphates. When the proportion of ordinary sulphates to the conjugated or aromatic sulphates is ten to one or less, intestinal autointoxication is present. The same condition is indicated by a marked amount of indican in the urine.

Pœhl believes the abnormal metabolism that results in autointoxication to be due to a diminished intra-organic oxidation. This is due to: Deficiency of oxygen or diminished alkalinity of the blood, in a normally alkaline blood. Leucocytosis occurs, with a considerable destruction of white blood-corpuscles, which sets free spermin. This latter substance acts as a ferment that hastens the oxidation in the tissues. The lowering of the alkalinity of the blood is a potent factor in increasing the susceptibility of the system to infection, as has been shown by the researches of Von Fodor,[3] Behring,[4] Calabresse,[5] Cantani[6] and others. This condition is shown, according to Pœhl, by the analysis of the urine. If the amount of disodium hydrogen phosphate falls below 50 per cent. of the total phosphates there is lessened alkalinity, and autointoxication has begun. The coefficient of Zerner, which consists in the ratio of uric acid to the total phosphates, is of value. A ratio higher than 0.4 per cent. indicates lowered alkalinity. The relation of the chlorids to urea may also be taken as a similar measure; it should not be less than one of NaCl to two of urea. Armstrong[7] cites the port-wine color given to urine by the addition of ferric chlorid as an indication of autointoxication. This reaction occurs especially in cases due to dilatation of the stomach.

The symptoms of autointoxication are very various, and many grave conditions have been traced to this source. Among the severe forms of disease that have been shown to be the result of autointoxication are the following: Epilepsy,[8] neurasthenia,[9] migraine,[10] neuralgia, tachycardia,[11] Basedow's disease,[12] asthma,[13] tetany, gout, amblyopia,[14] albuminuria,[15] urticaria.[16] Dr. Talbot has shown that intestitial gingivitis is one of the first, if not the first, symptom of autointoxication. Recent researches of Vaughan Harley indicate that scurvy is caused by ptomains from tainted meat and the condition of the gums in scurvy is closely allied to that of pyorrhea.

In its milder forms we may usually describe the course of the symptoms as follows: One of the most prominent symptoms is headache, which varies in severity according to the sensitiveness of the subject. Poisons produced by autointoxication usually cause contraction of the arterioles, with consequent rise in the arterial pressure. This rise of blood-pressure may so stimulate the kidneys as to increase the quantity of urine and cause the elimination of the poison. In these cases the symptoms produced by the poisons are wanting or insignificant. If the rise in blood-pressure is considerable, the symptoms of asthma may supervene. M. Huchard[17] states that in some cases the contraction of the vessels may be so great as to produce a pallor that simulates chlorosis. In such cases the pallor disappears upon regulation of the diet, by the removal of meat, so as to prevent the formation of the toxin which produced the contraction of the vessels. On the whole the contraction of the blood-vessels, and consequent rise of blood-pressure, must be regarded as salutary, being a provision of nature for the elimination of the poisons. Other symptoms are due to the elimination of waste material by other emunctories than the usual ones. The natural excretions do not seem to produce any disturbance in the eliminating organ, but an unusual poison will produce violent symptoms by irritating the organ by which it is excreted. Thus when the kidneys are performing their functions imperfectly the skin or bronchial mucous membrane shows irritation in consequence of vigorous efforts at elimination. As a result of these efforts there may be itching of the skin, eruptions of urticaria, eczema or cough and bronchial irritation extending even to catarrhal inflammation. Salivation is an occasional symptom. We know that mercury is eliminated in the saliva, and the same is doubtless true of other poisons, including those of autointoxication. J. C. Simpson[17] thinks that the salivation of pregnancy is due to a toxic substance absorbed from the uterus. Bouchard has isolated from the urine of healthy men a substance that will produce an increased flow of saliva. Salivation may, therefore, be regarded as one of the danger signals in autointoxication.

---

*Presented in a symposium on Interstitial Gingivitis, to the Section on Stomatology, at the Fifty-first Annual Meeting of the American Medical Association, held at Atlantic City, N. J., June 5-8, 1900.

**Hunter has attributed infection of the stomach and consequent pernicious anemia to germs swallowed from the mouth.

The constitutional treatment of interstitial gingivitis resolves itself into the treatment of autointoxication, and especially of those forms that are liable to cause the disease.

Three indications are to be met in the treatment: 1. To stimulate the eliminating organs; 2, to fortify the system against the action of the poison; 3, to prevent the formation of the poison.

The three important emunctories through which poisons—whether introduced from without, or produced in the system itself—are eliminated are the skin, kidneys and bowels. Of these the skin is the most accessible, and ought to be most susceptible to treatment.

That even metallic poisons can be eliminated by the skin is shown by the elimination of lead in this manner, and by the deposition of silver in the skin when the metal is given for a long time. A similar function is shown by the formation of crystals of urea on the skin in cases of kidney disease, where the eliminative action of the kidney is impaired.

The therapeutic problem in the treatment of gingivitis will best be solved by methods that serve to keep the skin up to its highest efficiency as an eliminative organ, rather than by spasmodic stimulation followed by periods of inaction. Hygienic measures should be utilized to the utmost, while drugs should be used only as adjuvants. The conditions under which the skin reaches its highest efficiency as an eliminating organ are warmth, cleanliness, free cutaneous circulation and an abundant supply of moisture. To secure these conditions requires the attention of the physician to the subject of clothing, but it is beyond the scope of this paper to enter into details in regard to this subject.

The importance of an equable temperature for all parts of the skin is shown by the results of experiments, which indicate that chilling of certain areas of the skin affect the circulation of the internal organs, and also tend to lessen the rapidity of circulation in the skin of other parts. Elimination by the skin is promoted by a judiciously applied hydrotherapy, but the external use of water accomplishes much more, so that several indications are fulfilled at the same time. Warm or hot baths and the friction that follows them promote a free cutaneous circulation. The value of the Turkish bath is well known, but its expense and the danger of subsequent chill tend to limit its utility. The old-fashioned alcohol sweat acted on the same principle, and was a powerful therapeutic agent. The bath cabinets now on the market seem destined to remove the objection of expense, and the use of the hot-air bath deserves the attention of the profession for the relief of autointoxication as well as in the treatment of more serious affections, like dropsy and uremia. It should be given under careful direction from the physician or medically educated dentist, who should be well acquainted with its physiologic action as with the action of the drugs which he employs. For the treatment of migraine Steel[18] recommends, in addition to a vegetable diet, the use of hot vapor baths, cold sponging and vigorous rubbing, suiting his measures to the condition of the patient, and using one or all, according as his judgment determines. He reports very gratifying results. We have in the cold bath a powerful agent for the stimulation of the nervous system, for increasing the alkalinity of the blood and profoundly influencing the metabolism of the tissues.

Strasser found that cold baths increased the alkalinity of the blood. The cold bath by its temporary contraction of the arteries drives the blood more rapidly through the kidneys, liver and other internal organs. and thus improves the action of the other eliminating organs as well as the skin.

Armstrong[7] recommends the use of the needle spray and general faradization. He also recommends, as a means of stimulation of the nervous system, an application of mustard, which he calls the double-mustard pack. This is made as follows: Two large poultices are made of mustard bran and applied, one to the nape of the neck and down the spine, and the other over the region of the stomach and liver. The application is made for fifteen minutes every second day.

While the free action of the skin is to be encouraged, it should not be carried too far or adopted as an exclusive method of treatment. Bouchard[18] suggests that too free action of the skin may be prejudicial by lessening the activity of the kidneys, and thus in some cases inducing rather than preventing autointoxication. This condition is noticed in summer, when, with excessive sweating, the urine becomes scanty and irritating, and at the same time the skin is affected with pruritus or with urticaria. This danger is, however, easily guarded against by the free use of fluids.

The importance of excretion by the kidneys has never been overlooked by the profession, and the means by which it can be promoted are well known. Diuresis depends upon two factors: increase in blood-pressure and stimulation of the kidney epithelium. The increased blood-pressure is promoted by two means: contraction of the arterioles and increase in the force of the heart's action.

As has been said, the contraction of arterioles by most auto-poisons tends to bring about their own elimination if the heart acts with sufficient vigor, and all that may be needed to secure the elimination of the poison is to secure the vigor of the heart, and in cases where the formation of the poison has ceased, this will terminate the disease. Digitalis acting as a heart tonic and raising the blood-pressure at the same time, stands in the front rank as a diuretic, and may often act favorably when there is no heart lesion to require it. Caffein appears to act not only by stimulation of the heart but also by a special action on the kidney epithelium. The close relation of caffein to bodies of the xanthin group renders its employment of doubtful utility in cases where the intoxication is due to the presence of this group. In cases of doubt it is probable that an estimation of xanthin bases in the urine might be a valuable guide in deciding whether to employ caffein as a remedy, or to exclude coffee, tea and chocolate from the dietary.

The saline diuretics act by their influence in withdrawing water from the tissues and thus increasing the volume of the blood. They are thus well suited to the removal of poisons that have been deposited in the lymph-spaces, and ought to be especially useful in the treatment of gingivitis. The action of alkaline diuretics also promotes oxidation and thus they serve a double purpose.

The free imbibition of water affords the readiest and best means of sustaining the action of the kidneys. That the American people drink an insufficient amount of water is shown by the fact that the average amount of urine is less in this country than in other countries. When the daily amount of urine is less than three pints a good indication is afforded for the administration of water and diuretics. It will often be found to be less than a quart.

The water will be taken more freely and with less repugnance if it contains a small amount of salts. An alkaline mineral water containing only a small amount of solids is especially suitable for the purpose. The amount of water used should be such as to materially increase the amount of urine.

The eliminating function of the large intestine is shown by the fact that mercury is eliminated by this channel, even when it has entered the system by other avenues than the stomach. That the liver also acts by eliminating poisons in the bile is well established. The cure of autointoxication demands, therefore, the use of agents to stimulate the liver and the large intestine. Calomel has long held the confidence of the profession as an agent that produces an increased action of the liver, and clinical experience seems to justify the continuance of the confidence. The question has not been settled experimentally, but the favorable effects derived from it in practice indicate that it must act in some way not yet revealed by experiment. The further action of calomel as a purgative renders it an invaluable agent in the treatment of autointoxication.

The use of purgatives can not well be considered separated from their action as eliminating agents. The value of purgation is generally recognized, and we can only add some recommendations as to the particular agents to be used. Prof. H. A. Hare[10] recommends the following pill in the treatment of a case in which epileptiform convulsions were due to autointoxication:

℞.	Extract chiretta	gr. ii
	Leptandrin	gr. ss
	Podophyllin	gr 1/5
	Euonymin	gr. ss
	Beechwood creosote	gr. ss

M. Ft. pil. Sig. One to be taken three times a day, after meals.

In addition he gives Hunyadi water in sufficient quantity to secure a semifluid stool.

Prof. D. R. Brower[20] in the treatment of neurasthenia due to autointoxication recommends four parts of sodium sulphate to one part of sodium phosphate as a purgative in intestinal dyspepsia.

The defenses which the organism possesses against the action of poisons are: 1, the power of the liver to destroy poisons absorbed from the intestines; 2, the general oxidizing power of the system; 3, the action of special organs such as the thyroid. To fortify the system against the action of poisons we need to stimulate these activities. A large proportion of the toxic substances whose actions produce the clinical picture of autointoxication consists of immediate links between the albumin molecule and the final results of oxidization produced by the metabolism of these substances in the body. The final products of oxidation are comparatively harmless, while those substances which represent a less advanced degree of oxidation are usually poisonous in proportion to their remoteness from the final product of metabolism. Thus urea is harmless, while uric acid, which represents a lower degree of oxidation, is irritating and somewhat poisonous, and xanthin, which contains less oxygen than uric acid, is more decidedly poisonous than the latter. Lastly we have adenin, which contains no oxygen and is a powerful poison. In all probability the most poisonous leucomains are complex compounds more nearly allied to albumin, which have not been isolated. The more complete the process of oxidation in the system the less the organism will be affected by the poisons of autointoxication. If, therefore, the natural oxidizing processes of the system can be promoted, these substances will be converted by oxidation into less noxious or harmless compounds whose excretion is easy. The process of oxidation in the body is a function of the cells and is carried on best in an alkaline medium. The alkalinity of the blood is known to increase in the progress of an infection *pari passu* with the acquisition of immunity by the organism and the destruction of the toxins of the disease. A similar process goes on in the recovery of the organism from autointoxication.

The alkalinity of the blood may be kept at its maximum by securing the excretion of acid by the kidneys and skin, by preventing the formation of acid, by the administration of alkalies, and by the use of a meat diet.

The administration of the alkalies does not markedly influence the alkalinity of the blood, but there is no reason to doubt that they affect the reaction of the lymph and increase the oxidizing powers of the system. The oxidations going on in the system, depend upon the activity of the cells and, therefore, will be favored by the renewal of the lymph which bathes these cells. The beneficial effects of massage find in part their explanation in the increased activity of the lymph circulation which it brings about. The cold bath as a means of stimulating the nervous system has already been referred to. Tonics like strychnin have a similar action.

Is is possible to introduce into the system oxidizing agents that will act either independently or in conjunction with cellular activity to promote the oxidation and destruction of poisonous substances circulating in the blood? On the discovery of the active oxidizing powers of certain agents it was assumed that they could be made to give up their oxygen inside the body as they do outside and thus affect therapeutic results.

By many physicians it was once thought that, in potassium chlorate we had a source of oxygen as available when taken internally as when used in a retort in a chemical laboratory. But experience has shown that such analogies can not be pressed too closely and that the process of oxidation in the system goes on by the intervention of the chemistry of the cells and probably in no other way. It is quite possible that the cell may make use of extraneous oxidizing agents as it uses the iron of the red blood-corpuscle for the purpose of carrying oxygen.

Ratchford[21] recommends potassium permanganate to neutralize poisonous ptomains circulating in the blood. He gives it in pills coated with salol, each containing one grain. One of these is taken three times a day, an hour after meals. In addition to the permanganate he gives a mixture of sodium salicylate, sodium phosphate, and sodium sulphate. It is improbable that potassium permanganate acts as an oxidizing agent after absorption into the blood. The results of its use in opium poisoning seem to show that it is efficacious by oxidizing morphin in the stomach, but does not act after absorption[32]. It has been suggested by Prof. W. S. Haines that hydrogen dioxid might act after absorption into the blood, because it has been shown that it can exist in the blood. Pœhl would employ spermin for this, while others recommend nuclein. Poisons absorbed from the intestinal canal are largely destroyed by the liver. This is well illustrated by the formation of urea from ammonium carbamate by the action of that organ. If the liver be removed from the circulation by making an Eck's fistula so that the portal blood is carried directly into the vena cava, urea is no longer formed, but instead the blood becomes loaded with ammonium carbamate, which is a powerful poison producing symptoms similar to those characteristic of uremia. That the liver performs a similar function with regard to other poisons is well established. The regulation of the action of the liver is, therefore, of prime importance in the treatment of any disease depending upon autointoxication. For the stimulation of the liver only two drugs seem to be effective, sodium salicylate and inspissated bile. Of these, the latter is doubtless preferable as being more of a physiologic agent. The abandonment of sedentary habits and the use of fresh air and exercise are to be recommended where there is reason to think that the liver is inactive.

In this connection we may speak of a maneuver suggested by Moebius[22], and which he states he has practiced on himself with great success in relieving certain pains attributable to congestion of the liver. It is probable that this maneuver would be useful in stimulating the liver to perform its functions. Moebius terms this procedure, hepatic massage. He describes it as follows: He first takes a deep inspiration, by which the liver is depressed one or two centimeters below the edge of the ribs. He holds his breath as long as possible and then expires slowly. By this means the liver is compressed between the walls of the abdomen and the diaphragm. The operation is carried out most advantageously when sitting in a rocker with side arms.

Second in importance to the liver stands the thyroid. The chemistry of the thyroid offers some explanation of its action and of the use of two remedies which have heretofore been classed as alteratives without our being able to give a satisfactory reason for their action.

The discovery of thyroiodin by Baumann and the demonstration of the marked therapeutic effects of thyroid extract and of thyroiodin in various diseases marked a great advance in scientific therapy. Recently Roos[23] has shown that the activity of the thyroid depends upon the iodin-containing substance and is greatly increased when the gland contains much iodin and fails entirely when the gland is free from that substance. In the wild state, herbivorous animals contain more iodin in the thyroid than carnivorous, whose thyroids are sometimes free of iodin. With dogs, however, the amount varies with the food, being small or wanting on a meat diet, increasing with a mixed diet, and being very large when doses of iodin are administered in addition to that contained in the food.

The researches of Blum[24] led to the conclusion that the thyroid acts by storing iodin in its substance, which it causes to combine with toxins, forming toxalbumins partly saturated with iodin, which gradually renders them innocuous. The fact that this toxalbumin does not produce its effects on metabolism during life indicates that it does not pass into the circulation. This is further indicated by the fact that long-continued withdrawal of iodin from the food does not affect its removal from the thyroid. When, however, iodin is administered, the amount in the thyroid increases. If, as these researches indicate, the action of the thyroid is dependent on its iodin and consists in the destruction of toxins or toxalbumins, by separating them from the blood and combining them in its substance with iodin, the utility of the iodids is explained. The fact that the iodin acts through the metabolic changes in the thyroid would make it probable that the most efficient method of administration in autointoxication is by means of small doses extending over a long period of time. It is doubtful if doses large enough to enable the element to be detected in the urine should be given. The value of a mixed diet as affording a source for thyroid iodin is also indicated.

Recent researches by Gautier[25] have shown the presence of iodin in organic combination of sea-water, and it is probable that it is present to a very slight extent in all ordinary potable waters. The experiments of Oswald[26] show that the iodin-containing substance of the thyroid contains very nearly the same proportion of iodin as the iodin-containing proteid of sponge, known as spongin. It is possible that spongin might be an acceptable form in which to administer iodin.

Further researches of Gautier[27] show that arsenic is also a constant constituent of the thyroid, existing there in very minute quantity. This may also explain the valuable alterative properties of arsenic.

The third purpose of the treatment of autointoxication is to prevent the formation of leucomains, ptomains and toxins. The point of origin of these poisons can not always be ascertained, but careful search for all complications which might give rise to the absorption of toxins from the various mucous surfaces should be made. The nose, pharynx and tonsils, as well as the genital tract, should be scrutinized, and any disease found should be treated so as to prevent the absorption of poisons from these sources.

There is no doubt that in many cases putrefactive changes go on in the stomach or intestines, where we are not able to classify the disorder as a recognized disease of the stomach or intestines. These cases must be classed clinically as autointoxications, and the obviously rational treatment of them is the prevention of the formation of the poisons by fermentation.

The limits of this paper forbid our entering into a full treatment of the subject of intestinal antisepsis. We may attempt to control gastrointestinal fermentation: 1, by diet; 2, by excluding germs from the food before it is taken, and preventing their mixture with it in the mouth or the stomach; 3, by securing proper digestion, and increasing the natural antiseptic elements of the digestive secretions, viz., HCl in the gastric juice and bile in the intestines; 4, by securing the prompt passage of the food along the digestive tract and the prompt evacuation of feces; 5, by the administration of drugs as antiseptics.

While the exclusion of germs from the food may be impossible, their number should be reduced. In addition to the ordinary cleanliness and thorough cooking of food the cleansing of the mouth before and after each meal should be insisted on. Lavage of the stomach, or the use of large amounts of hot water before meals may be useful.

The secretion of gastric juice should be promoted by removal of all irritants, by cheerful surroundings at mealtimes, nerve tonics such as the cold douche, electricity, strychnia, etc. In cases where these measures fail, the administration of hydrochloric acid after meals should be resorted to, thirty minims of the dilute acid being given in two doses, one dose half-an-hour, the other an hour, after eating.

The antiseptic power of the bile has been denied on the strength of experiments which show that pathogenic organisms flourish in it. While this is true, we must concur in the opinion of Dr. Dock[28], who says: "Yet the changes in the odor of the intestinal contents in the absence of bile suggest that it may influence the forms of putrefaction and after the conditions of bacterial life in the intestines in ways that may be of great pathologic and clinical importance."

The prompt removal of feces from the alimentary canal is promotive of intestinal antisepsis. Vaughan Harley and Francis Goodbody have shown that washing out the large intestine by copious enemata is capable of decreasing the aromatic sulphates in urine and therefore causes a diminution of intestinal putrefaction. Calomel and other laxatives, even when they do not act as decided purgatives, diminish the amount of putrefaction in the intestine.

A desirable antiseptic drug should have the following characters: 1, it should have antiseptic power; 2, it should be non-toxic; 3, it should act through the whole length of the intestine. The least toxic drug fulfilling these conditions is charcoal. It is of very feeble antiseptic power, but it is non-toxic, non-absorbable, and acts through the whole length of the alimentary canal. Its power of removing alkaloids from solution makes it desirable for use in case we suspect the absorption of ptomains. It is highly recommended by Bouchard in his work on autointoxication.

Naphthol is a drug which has considerable antiseptic power and is not absorbed in sufficient quantity to produce toxic effects. Dr. Brower recommends benzonaphthol in ½-gm. doses, four times a day. Orphol, or beta-naphthol bismuth, combines the virtues of naphthol and bismuth and is deserving of trial as an antiseptic. The same may be said of eudoxin, or tetraiodophenolphthalein bismuth. The ordinary salts of bismuth are useful.

Salol, while much used, has two disadvantages: 1, it does not act in the stomach; 2, it is decomposed and absorbed from the upper part of the intestine and therefore does not act through the whole intestinal canal. It is also distinctly toxic in large doses.

The metabolism of the nervous and muscular systems is a source of poisoning. The production of lactic acid, creatin and other toxic substances occurs normally in the muscles, and excessive use of the muscles, or the moderate use of them in conditions of the system of which the oxidizing power is low, may result in such an accumulation of toxic material as to give rise to disease. In such cases the remedy is to reduce temporarily the amount of waste of the muscles by rest and to restore the normal power of oxidation and elimination. What is true of muscular exertion is equally true of nervous and mental exertion. Betscherew has suggested that fatigue, mental overwork and sedentary habits may disorder intestinal circulation and digestion, and so favor the production and absorption of toxins.

There is no more important element in the treatment of these diseased conditions than diet. We have to consider diet in reference to its composition, its digestibility, its liability to fermentation, and its relation to metabolism. Man is an omnivorous animal, and the dictum that "if we wish to be happy and healthy we must live on vegetable diet" is not justified by experience nor by science. Except as a temporary measure the diet should be a mixed one, containing the due proportion of proteids, carbohydrates and fats, with the organic salts derived from vegetables.

The evil effects of deviation from the normal diet are well illustrated, as Chittenden[29] remarks, by the production of acetone, probably from the metabolism of the fats, when carbohydrates are removed from the food. This is also shown by the influence of deprivation of fats in producing rickets. The composition of the food is also important from the fact that certain foods contain the precursors of some of the poisons which cause autointoxication. Thus uric acid and the members of the xanthin group are the result of the metabolism of the nuclein of the food. The foods that contain nuclein may be actually poisonous to persons that are affected with the so-called uric-acid diathesis. These foods are not, as has been supposed, the pure proteids or the flesh-food simply, but the animal food that consists largely of cells, and also vegetable foods that contain much nuclein, such as beans and peas and foods containing much seeds. Thus the experiments of Taylor[30] have shown that more uric acid is excreted under a vegetable diet consisting largely of peas and beans than under a diet of lean meat.

An important function of proteid food in carnivorous animals, and probably in man, is to maintain the alkalinity of the blood. Carnivorous animals withstand the effects of acid much better than herbivorous, because they are able to neutralize the acid by ammonia formed from the proteid materials of their food. This fact should not be forgotten in the treatment of autointoxication. The carbohydrate elements of the food are especially liable to yield acid products by imperfect oxidation, and should, therefore, be restricted in amount. Food that is easily digestible should be chosen. Carbohydrate food is especially liable to fermentation, and moderation in its use should be enjoined in cases where there is liability to fermentation in the intestines.

Authors differ somewhat in their recommendation of diet for the conditions due to autointoxication.

Hare recommends a diet free from fat. Huchard recommends a milk diet, and claims that by this means he can cure dyspnea and asthmatic symptoms in certain cases, while a return to a meat diet will bring on a return of the symptoms. Stekel reports a case in which migraine was brought on whenever the patient ate eggs. Armstrong[31] recommends for certain cases of gout, in which he believes there is autointoxication, the Salisbury treatment. This is carried out as follows: From three to five pints of hot water are taken per day, one pint before each meal. The diet consists exclusively of red meat without fiber or fat. No carbohydrates are allowed, except a half-slice of bread, cut very thin, and thoroughly toasted. Occasional aperients are given, and, if necessary, potassium citrate is administered to facilitate the excretion of uric acid. This diet is successful in some cases of gout that have resi[illegible] e usual methods of treatment. Its [illegible] ined as follows: It excludes the [illegible] eaily favor fermentation; it [illegible] gonisms which are found in the stomach and intestines, and promotes the alkalinity of the blood. In addition, it does not introduce much nuclein, so that it does not tend to increase the amount of uric acid and its congeners in the blood.

The constitutional treatment of gingivitis due to poisonous metals or drugs, as well as that due to scurvy, must be conducted on the same principles as when due to autointoxication. In all these affections the physician must bear in mind the various factors that enter into the causation in the case in hand, and adapt the treatment to the individual patient on the principles which we have endeavored to state and illustrate.

It is to be hoped that future investigations will enable us to trace the symptoms of autointoxication to the specific poisons from which they arise, and to adopt a specific antidotal treatment. But whatever the advance made in this line, it will remain true that our chief reliance in treatment must be upon judicious efforts to aid nature to eliminate or destroy the poisons of disease.

LOCAL TREATMENT OF INTERSTITIAL GINGIVITIS.*

M. H. FLETCHER, M.D.
CINCINNATI, OHIO.

Talbot, when treating of interstitial gingivitis, says: "The exciting causes are either constitutional or local, but as a rule are local, or have local action." Regarding his experiments on dogs, he says: "While it is by no means improbable that constitutional factors assist in its early progress in man, still the exciting cause of this disease is tartar." Dr. G. P. Carpenter's experiments tend to establish the law that without a locally exciting cause the disease would not exist as such. The writer is in full accord with these opinions; consequently, from his standpoint, the natural and all-important treatment is to first remove the local cause, by cleansing away the deposits found about the teeth, either superficial or deep-seated. This being accomplished, local germicidal and palliative treatment should be adopted and continued until health is the result, or failure established. To accomplish these ends many methods are pursued, but all must attain the same end before recovery can take place, namely, removal of the exciting cause, for the laws of growth and repair are always the same under the same conditions, and if the cause be removed before it is too late, complete recovery is the result, without further assistance from the physician, and, doubtless in many cases, in spite of him.

For convenience in classifying we make three arbitrary divisions, as follows: acute, chronic, and sloughing stages of the disease. The writer, after examination, appoints the earliest date possible for beginning the removal of deposits. The majority of these deposits are hard, but many are soft and cheesy, especially in young patients, and even these soft accumulations may produce the incipient or acute stage of the disease. It is the writer's opinion that these early and softer deposits and their consequent irritation, produce "the point of least resistance," which, in systemic dyscrasia, may terminate in the utter destruction of parts involved. In this stage, the complete removal of these deposits in one or more sittings, usually suffices for recovery as to local symptoms; if constitutional treatment is needed it most properly begins with the local work. The younger the patient the oftener and more watchful should be the attention in order to prevent progress of the disease. This treatment may be made three or four times a year, and to be continued indefinitely.

In the second or chronic stage, we will assume the tissues are diseased or destroyed one-third the distance from the normal gum-line to the apex of the tooth, involving the alveolar process with the outer periosteum and the gum tissues. In this instance, as in the other, all deposits must be removed, and infected bone taken away; this will require from three to ten sittings, from a week to ten days apart.

The sloughing stage may be defined as that wherein so much of the tissues have been lost that the tooth is abnormally loose, indicating that more than half the bony support has disappeared. To induce recovery in this class of cases, demands of the practitioner his keenest knowledge of pathology, and his greatest skill in assisting nature to produce what the surgeon would call a "healthy stump." The procedure here is the same as in the previous stages, excepting that it requires much more care, and very greatly increased diligence, expecting the time for recovery to be much longer, if indeed it can be accomplished at all. In these cases, like all other pathologic conditions about the body, absolute reliance may be placed in the laws of repair, for there is a constant and continual effort on the part of nature to maintain the normal, and if we, as practitioners, are bright enough to remove exciting causes, we have done all that it is possible to do. This idea would include what we call palliative, stimulating, and antiseptic treatment. During this time we should keep constantly in mind the fact that we are merely trying to assist nature to accomplish what the laws of the universe are compelling her to do.

In removing deposits, each operator must select and use those instruments best suited to his individuality and the needs of the case, the necessity being to absolutely remove all deposits. It has been found that clean dentine or cementum, without peridental membrane, is, at least, *non-irritating*, while deposits of *any kind upon* the root surface irritate, and will stimulate a continuous effort on the part of nature to get rid of it. In this instance, however, the effort to get rid of foreign bodies fails of its object on the intruder, but acts on the surrounding tissues and destroys them; hence the pathology of the disease. The complete removal of deposits having been accomplished, the attention should now be directed to the alveolar process, and dead bone or other foreign substance taken away. In actual practice, the work necessary to remove deposits usually removes all other irritating substances. Dead tissue may be absorbed, but these deposits never are; hence the necessity of their removal.

---

*Presented in a symposium on Interstitial Gingivitis, to the Section on Stomatology, at the Fifty-first Annual Meeting of the American Medical Association, held at Atlantic City, N. J., June 5-8, 1900.

If it were possible for all this to be perfectly done at one sitting, and the wound dressed and allowed to remain quiet and in perfect position, as can be done in other parts of the body, then no further attention would be necessary, aside from one or two redressings, several days apart, to maintain antisepsis. A week or ten days is suggested, for the reason that this length of time is usually necessary in the process of healing, for new material to be formed. To irritate a wound with treatment every two or three days would seem a hindrance rather than a help to the process of repair, and this seems especially true with the sockets of the teeth.

One of the most impressive, and I might say astonishing, things that has happened to the writer was viewed while pursuing embryologic studies in the laboratory. To watch, through the microscope, the manner in which channels, or blood-vessels are formed in embryonic tissue or blood-clot was fascinating beyond measure, leaving an impression never to be effaced. The blood has many important offices, not the least of which is that of clotting. A minor wound which can fill itself with blood-clot and be kept aseptic, will sooner or later be rebuilt with its own kind of tissue, providing, of course, the power of the organ to functionate has not been destroyed; should this function be performed, then a healthy stump, or scar material of the next adjoining tissue, is the natural result. To destroy or even disturb blood-clot in an aseptic wound, within twenty-four or forty-eight hours after it has formed, is simply tearing down or injuring the false or preliminary scaffolding that nature has constructed for the rebuilding of lost tissue, hence the necessity of allowing a wound to remain quiet until sufficient effete matter has accumulated to need removal, which is usually about a week or ten days.

If this view be accepted, then the typical procedure would be to remove, at one sitting, all foreign matter in or about the sockets of the teeth. The endurance of the patient might compel this to be confined to one or two teeth; this being accomplished, sterilize the wounds with medicaments, and permit them to fill with blood-clot, allow this clot to remain undisturbed so long as pus does not form. Just previous to, or at the time this stage arrives, the surplus matter should be taken away very carefully, but the new granulations should be most cautiously guarded from violence, if the most satisfactory results are to be obtained.

In actual practice, however, I believe most of us go over much of the field in one sitting, and often to the limit of the patient's strength. If several teeth can be thoroughly done at one time it is well; but the typical way, as stated, is to so do the work that no second scraping or cutting will be necessary, any more than an amputation should need be done the second time. Now, if the patient return in a week or ten days, a much improved condition can be seen, and where the work has not been perfectly done, there can be seen near the gum margin, dark or bright-red spots where deposits have not been removed. If this deposit be deep in the socket, then lack of granulation tissue and pus will be the result, and other attempts must be made until the point of recovery or failure has been reached.

For removing deposits the writer uses such instruments as are illustrated by Talbot, in addition to those styles recommended by Drs. Henry H. Tompkins and Storer How. I find instruments shaped like Dr. How's fissure chisels, of the greatest value in removing deposits from the approximal surface of the roots, for they are thin, strong and efficient, their varieties in shape will enable one to reach nearly all the approximal surfaces.

The medicaments used for treating the sockets may be any suitable antiseptics and stimulating remedy, and even escharotics may be applied with advantage to destroy tissue and bacteria, and produce a healthy aseptic wound, this latter condition being the true fundamental principle of repair. The writer's practice is to use 5 per cent. tincture of iodin in 50 per cent. alcohol, to which is added as much oil of cinnamon as will be held in solution by the alcohol. After the use of the instruments, this is injected into every part of the sockets with a hypodermic syringe, until the blood starts again, then the patient is discharged for one week or more. This treatment is continued until recovery of all the teeth is complete, or the best stage possible reached, in any event, retaining all teeth as long as practicable. Complete recovery of all cases, however, is far from the writer's experience.

Accompanying office treatment, the patient should be required to carry on vigilant attention to the case; satisfactory co-operation of the patient, however, is not always easy to obtain. This is so often true that I deliver stereotyped lectures in each case, on brushes, picks, dentifrices, and their use, with imperative and dogmatic instructions as to their continued use, believing that if the teeth are kept absolutely free from mechanical irritation or deposits, the disease, as we now know it, is practically out of the question.

A stiff serrated brush of the best quality with the rows widely separated, is recommended, with instruction to allow at least one-half of the width of the brush to rub the gums. This not only insures the removal of lodgement and deposits about the necks of the teeth, but gives a necessary massage treatment to the gums, keeping them hard and healthy.

Tooth-picks of soft wood are recommended for use between the teeth. These should be thick enough to rub against the teeth on either side, thus preventing accumulations on the approximal surfaces at the necks. Soft pine or other light wood serves best for this purpose, whittled flat and thin at the point, then gradually becoming thick enough to do the work well on both approximal surfaces. The hem of a handkerchief or other fabric may be used to advantage when the teeth are not too close together. Whatever plan is adopted the approximal surfaces at the necks should have exceeding care, for this is the locality first and most frequently attacked by the onset of the disease.

The fact that these localities are inaccessible to the cleansing action of food, tongue and lips, as well as to the brush, and that here the accumulations and disease most often make their start, tends to strengthen the belief that without local irritation the disease would not exist. It is our belief that these particular localities do not receive adequate care, either from the patient or practitioner, principally because they are inaccessible and troublesome to care for, but for this very reason, they should have cautious and particular attention, especially in cases predisposed to gingivitis. For this purpose there seems to be nothing better in the patient's hands than the tooth-picks of soft wood, referred to.

The matter of leaving injurious splinters in the gums is far-fetched, for if such a thing should by chance occur, the splinter would be discharged from the gums in the same manner as it would from any other part of the body with but temporary soreness. However, brushes and picks alone, fail of their object unless they be accompanied by an efficient powder. A false idea about powders for cleansing the teeth seems always to have prevailed, as it does to the present day, namely, that a powder to cleanse the teeth must be capable of polishing them, and on that idea, tooth powders have been compounded from time immemorial, when the fact is that the natural polish of the teeth is almost universally the best they can have. Abrasives, such as chalk, sea-shells and pumice stone, not only polish the enamel, but in time cut into the dentine at the necks of the teeth, which both dentists and patients know to their sorrow. The teeth do not need polishing, but simply to be kept free from deposits and lodgements. If this can be accomplished I think no one need fear disease of the gums, which always precedes peridentitis in all its variations.

To the end of being able to use a dentifrice *ad libitum,* without danger of abrasion, and one coarse enough to take away all that a powder should remove, the writer has, for months past, been compounding and prescribing a preparation made from the hard parts of cereals, such as rice and indian corn. The grit in this powder does the work most thoroughly, without the least injury or wear, as must be self-evident. Pulverized cereal has been objected to on the grounds that it ferments in the mouth. This is wrong, however, for only hydrated starches ferment, and to hydrate it requires boiling, the action of caustic alkalies, or long continued action of bacteria.

With this pulverized cereal is incorporated 25 per cent. of soluble ingredients for sterilizing the mouth and neutralizing its acids. These ingredients are sodium borate, potassium chlorate, and potassium nitrate in some cases. The formula mostly used is as follows:

R.	Pulverized cereal	75 parts
	Sodium borate	18 parts
	Potassium chlorate	7 parts

Sweeten with saccharin, and flavor to taste.

As a dentifrice this cereal tooth-powder does no possible injury, even by excessive use, but is perfectly safe. It may be used freely and often enough to prevent any accumulations whatever on any surface accessible to a good brush. Under the use of this powder the accumulations are not only kept away, but the surface of saw-toothed abrasions at the necks of the teeth become dark, and loose their sensitiveness, showing that the abrasion has ceased. Many confrères in my own city, and some of those present, can testify to the efficiency of this formula, not only as a cleanser, but as a most satisfactory medicinal treatment. When there is no stomatitis or gingivitis, the medicaments tend only to keep the gums hard and the mucous membrane in perfect health.

The fallacy of splinters from tooth-picks, like that false idea of "injury to the gums by hard brushes," has been the negative cause of the loss of innumerable teeth to mankind. These ideas, coupled with the use of something gritty for polishing the teeth, are mistakes that should be stamped out of the profession by its thinking men. The failure to cleanse the teeth, the use of soft brushes and inefficient dentifrices, and the omission of tooth-picks are the great negative causes of the disease under discussion. Civilization may be held accountable for such omissions, and we, as custodians of the organs involved, are directly responsible for much ignorance in prophylaxis.

DISCUSSION ON INTERSTITIAL GINGIVITIS.

[The papers of Drs. G. L. Curtis, J. G. Kiernan and E. S. Talbot, belonging to this Symposium appeared in last issue.]

Dr. E. S. Talbot, Chicago—When I placed my book, "Interstitial Gingivitis," on the market, it met with considerable opposition from some of the ablest men in the profession. The point raised was that this was a local disease and not constitutional. In that work I said very little about the treatment of constitutional disease, for the reason that I wanted to develop a certain line of research, and to find some one capable, who had a large experience in the treatment of such conditions, before I undertook any further work in this direction. To offset the views of these able men—teachers and practitioners of dentistry—I formulated this symposium. Many of you, perhaps, are not familiar with the gentlemen who have responded to my request. I can assure you that in the West they are the ablest men we have in their various departments. They are men who have had life-long experience, and who have reputations in the special branches they practice. The object has been to show—which I think they have conclusively—that interstitial gingivitis, or pyorrhea alveolaris is due in a measure to constitutional causes. The very able paper by Dr. Curtis, and the illustration which he has presented is enough to show that syphilis is one of the marked conditions.

Twenty-four years' experience among the defective classes, paretic dementia, and other diseases of the brain, idiocy, ataxia, etc., has shown me that neurotic affections have much to do with this disease. This is also represented in practice by the degenerate patients.

So far as my own paper on indigestion is concerned, I think every dentist will agree with me that chronic dyspeptics suffer from this disease oftener than any other, except the tuberculous and syphilitic, patients.

The very able paper by Dr. Baum—who last year read a paper on the factors of syphilis—is certainly interesting in relation to the action of drugs. Those of you who have read my paper on this subject can say how very clearly I have drawn the knot around all these constitutional conditions, including scurvy and blood poisons, and have united them—as shown by microscopic slides—into one pathologic condition.

In regard to the treatment of these conditions, I must say that the paper by Dr. Salisbury is surely of great interest to us, and if this lesion is to be treated in an intelligent manner, we, as practitioners of chemistry, must know something of all the diseases of the human body. If we undertake by local treatment to restore the lost or diseased tissues to health, and ignore the constitutional conditions—which I believe are noticed in at least 95 to 97 per cent.—we shall certainly make very poor practitioners. In regard to the local treatment as suggested by Dr. Fletcher, I can endorse his method in almost every particular. Each one of us has his peculiar methods of treating these conditions locally, but the general outline, as laid down by Dr. Fletcher, is carried out, as a rule, by every practitioner. I do not use instruments in removing the local deposits at the first sitting, as a rule. I first obtain a sample of the patient's urine and examine it; in nearly every case it is acid. I immediately request my patient to drink from eight to twelve glasses of pure water—distilled or spring—every day. As there are forty ounces of water excreted from the body every day, if that amount be not taken into our systems we certainly can not remain healthy. At the first sitting I make an application of iodin, not a dilute application as recommended by the chairman, but the crystals of iodin, applying it until the gums are saturated and black. The iodin percolates through the gums and runs down between the gum and the tooth. The object is to reduce the inflammation, which extends all through the alveolar process and peridental membrane. Therefore, the constitutional condition of this disease should be reduced, as well as the interstitial gingivitis. If the gums are very badly inflamed, on the second or third day I lance them. The object in using iodin the first day and dismissing the patient for two or three days is that great pain would be produced by attempting to remove the deposits at that time, owing to the sensitive condition of gums and the necks of the teeth, but by using iodin and waiting, the sensitiveness is reduced to a minimum. After three or four days the deposit is removed, and massage treatment taken up. I depend more on the massage of the gums after the blood-letting than on any other treatment. The stimulation is necessary. The massage brush can not be used too freely. By this means the gums are contracted tightly over the alveolar process.

The gums should be examined and restored to health just as much as teeth are prepared and filled. It is a part of our specialty to keep our patients' mouths in good condition, and the gums must be treated. Massage brushes that reach the gums must be used. By the stimulation which their use gives, a majority of the cases are restored to health.

Pyorrhea, which is secondary, in many cases will cure itself: after the inflammation in the alveolar process, and the gum tissue has been reduced, pus will cease to flow. If, however, it does not, the use of oil of cloves or cassia, or other stimulant, is all that is necessary. I wish to say a word in regard to acids, such as aromatic sulphuric, lactic, etc., which have been highly recommended. There is not a surgeon living who would make such an application to inflamed bone in any other part of the body. Alkaline substances should be the basis of all preparations for cleansing the teeth and massaging the gums. A wash does not accomplish the desired results in the mouth for the reason that patients swash it around and think that all parts are cleansed. Therefore, I have discarded it to a very great extent. A tooth powder or a paste containing an alkaline substance is certainly more beneficial. I have been very successful in the use of a preparation that Dr. Fletcher has recommended, having used it for the last year. I consider it as being one of the best tooth powders.

Dr. Wilber F. Litch, Philadelphia—Interstitial gingivitis has been termed essentially a filth disease. I should call it a disease of functional and organic inertia, of which filth is one of the manifestations. In my experience it is a disease which arises chiefly in persons of sedentary habits, who live on a diet in which the proper balance is not observed between the needs of the system and the amount of fuel or food taken to supply it with vital energy; the result is faulty metabolism, and the accumulation in the system of those toxic principles to which Dr. Salisbury has called our attention.

Personally, I have very little faith in the permanently curative power of systemic medication in that class of cases, but rely on a proper regulation of diet, active exercise, and the cleansing and eliminative power of such natural agencies as copious draughts of pure water. The large amount of water which Dr. Talbot recommends, and which I presume he succeeds in getting his patients to imbibe, I find to be rather in excess, perhaps not of the needs, but of the capacity of the average patient. A good rule is to drink all that can be taken without interference with the digestive powers of the stomach. I find that water when heated is most eliminative in its character, and when taken half an hour before meals has a very stimulating effect on the kidneys and other excretory organs, while it does not cause the same gastric disturbances which a large amount of cold water will, especially when taken with meals.

The plan of local treatment recommended by Dr. Fletcher, proceeding from tooth to tooth, and removing as much as possible of all deposits in every case, is based upon sound principles. He does not claim to be always successful. There are certainly many cases where it seems to be impossible by ordinary mechanism to remove every vestige of calcareous depositions. In such cases we can only do the best we can and strive to do our work thoroughly. I agree with Dr. Fletcher that after one thorough local medication it is best not to meddle too much. Meddlesome surgery is bad surgery. Give nature a chance. The powder he recommends I have not had an opportunity to test personally, and I confess to being prejudiced against starchy powders of all kinds, and to a preference for alkaline powders, such as precipitated chalk and magnesia, even though slightly abrasive. Undoubtedly many of our powders have been too abrasive in character, owing not only to the nature of their constituents, but to the manner in which they are used. Friction should be employed with the brush alone, to be followed, after thorough rinsing of the mouth, by the powder applied lightly and chiefly as an antacid. I find the wooden toothpick objectionable for interspaces difficult of access, as between the molars. There is no flexibility in the ordinary wooden toothpick. Often by its use the gum is pushed away from the teeth to a destructive extent. I recommend the quill pick in all cases. An excellent agent for the removal of substances between the teeth is a strip of rubber. This being thin will pass between teeth which are in very close contact, and if the strip is broad, will wipe off deposits and remove foreign material much more effectively than floss silk. It is the difference between cleansing a surface with a thread and with a cloth.

Dr. A. E. Baldwin, Chicago—It is important to present the reasons for and against considering this disease, constitutional or purely local. It is impossible at this date to decide definitely whether it is clearly proved to be either one or the other. Many cases seem to be clearly of constitutional origin, and in others constitutional conditions clearly aggravate the trouble. I am opposed to the use of wooden toothpicks, and I think, though Dr. Fletcher considered lightly the consequences of splinters being left in the gums, that they do cause trouble and would better be avoided. I find the use of little rubber bands, which are so common, is worthy of trial. My patients use them and I find they keep the teeth clean, even better than floss silk. In regard to the autointoxication spoken of in the scholarly and interesting paper read by Dr. Salisbury, it seems to me it was practical to condense the subject for consideration. There are two thinks to which especial attention should be paid promptly. Of course, Dr. Salisbury goes into details further than I can in regard to the chemistry, the materials and the conditions, but the two things to be done, as far as possible, are, 1, to lessen the cause, and 2, do all possible to stimulate the excretory organs.

I do not agree with Dr. Talbot in discarding mouth washes. I favor the use of a good local wash. Dr. Talbot stated that after the termination of the local conditions, the treatment of pyorrhea would be very slight. In case all accretions are removed, and the parts restored to a natural, healthy state, the disease will cure itself; but to bring this about the whole system must be brought to a state of health. We are learning every day that the body is one organization and that the organs are dependent upon each other for well being.

Dr. E. A. Bogue, New York—Dr. Baldwin has just announced what I have been learning for some years, that all vital processes consist of a balance, and when that balance is disturbed there is disease. Dr. Salisbury, in his paper, came perilously near to another thought that has been announced as a fact, and is only a little way off from the subject under discussion; you will, perhaps, allow me to allude to it. The liver, in its process of disposing of sugar that has been taken with food, or of sugar formed in the stomach, succeeds much of the time—it is claimed most of the time—in sending a quantity of the sugar even so far as to show itself in the saliva. I mention this because in the treatment of pyorrhea I think it is an element which should be considered. If the physical system is in good condition, there is very little of this disease, very little dental disease of any kind. A few years ago I had occasion to examine the mouth of a gentleman 52 years of age. After searching an hour and a half for the cause of the trouble I discovered pyorrhea between the upper right wisdom tooth and the second molar. I also discovered a cavity at a point where the dentist had filled between the teeth. I was told by the gentleman that he never had a tooth-brush in his mouth. You would naturally expect that I found a filthy, dirty mouth, but I found [illegible] as [illegible] the mouths of any of us in this room. [illegible] of [illegible] en allu[illegible] to. He was in absol[illegible] c[illegible] that railroad contractor. [illegible] o[illegible] rse f[illegible] largely bread and meat. He used water as a drink and rinsed his mouth with two to four glasses of water after every meal. The consequence was, he was in good physical health, his teeth were well formed and well placed, and they were practically self-cleansing. The gums were in good condition, for they got a certain amount of the bruising or exercise which is needed by the human animal to keep him in good condition. What he took served as his medicine. He was regular in his habits, and was one of the finest specimens of the human being I have met in civilized society.

From that, I learned, among other things, not to use powder as my friend, Dr. Talbot, for the presence of the insoluble, mechanical, and abrasive in direct contact with the margin of the gums would serve as a nucleus for a deposit of those various pathogenic bacteria which are always found in the mouth. It is not easy to secure a soluble powder, though the S. S. White Dental Manufacturing Company have advertised one, which I have found was not soluble. Sugar of milk will dissolve, and perhaps that is the least deleterious of the soluble powders. On the other hand, it has seemed to me the amount of friction this gentleman gave his gums by his hard food was sufficient to keep them in good order. In the treatment of pyorrhea I should proceed differently from the treatment described by Dr. Talbot. I first use iodin and zinc to relieve the pain and then immediately proceed to remove all deposits. The aqueous solution of iodin and zinc I use is prepared as follows: Zinc sulphate as much as will dissolve in cold water. Dissolve 1 ounce potassium iodid in 2 ounces of water and add as much iodin in crystals as it will take up, then take equal parts of the two solutions and put them together. This will make something that is most efficient in the treatment of these conditions and which I have used with great delight to myself and to my patients.

Dr. W. E. Walker, Pass Christian, Miss.—I wish to give a word of testimony in favor of the stiff brushes, for I knew many practitioners who used soft brushes as I was taught. Ten years ago I ceased to recommend powders, and dropped them, as I found my patients would depend too much on the cleansing action of the powder and too little upon the brush. For the last five years I have given them the stiff brush alone, insisting more and more on its being used on the gums, as well as on the teeth. I use only the stiff brush and water. I find in the treatment of interstitial gingivitis that the patient gets better proportionately with the stiffness of the brush, as the massage of the gums by the brush is the important point.

Dr. G. V. I. Brown, Milwaukee—I am glad to see the discussion brought into the course of autointoxication. For practical purposes I do not think it advisable to go too far afield to find, in the majority of cases, what lies very near. If the rest of those present were surrounded as I am every day in the hospital with the giving of drugs, perhaps they would appreciate that all things are seldom what they seem. I have not much faith in the administration of drugs, strictly speaking, for any of these purposes. I believe in the stimulation of the glands for a time by the administration of drugs, but a considerable portion of the effect is necessarily lost after a few administrations. There is danger of an effect, which perhaps you know not of, being started up, possibly to counteract the very thing you are striving for. Such remedies as suggested, namely, of drinking water, and remedies that are applied directly to the surfaces affected, are undoubtedly safe. They promise a better result in long-continued use than would be obtained by internal administration of drugs for the specific purpose of stimulating any organ of the body.

One view of this matter has been overlooked. We have been describing here interstitial gingivitis, a condition of the gums and alveolar sockets which most resembles what we find resulting from the administration of many drugs mentioned in Dr. Baum's paper. How many of you have known in any part of the body an atrophy by reason of imperfect action of any of the organs, provided the part itself was properly used and kept in a reasonable state of health? When the gums are swollen, when gingivitis is present, there is a condition which accounts for destruction of tissue, but remember there are many cases in which there is gradual absorption of the alveolus surrounding the root, and a gradual contraction of the gum after many of these diseases. I would like somebody to account for this as a result of autointoxication. There is a stage of the subject which Dr. Talbot alluded to when he spoke of the frequency of pyorrhea among neurotics. This is accounted for in many ways, but before closing I want to call your attention to a condition which I have in mind. Take a child suffering from contraction of the spleen, due to a rickety condition. Does anybody believe that the administration of any of the drugs which is understood as valuable to overcome the disease, would cure the condition? Can the weight of the body bearing more on one side be remedied by the use of drugs? The part of the weight of the child will have to be relieved by properly supporting it, before we locally obtain the condition required. It does not follow that our tissue will be remedied by drugs, applicable to that disease. The same is true of pyorrhea. The restoration of a broken limb, or anything in surgery to health depends on granulation, and on the supply of new cells to take the place of those destroyed or lost. This can not be obtained while there is motion. The patient must be in condition so that nature can restore the integrity of the tissues.

I think it a fair proposition to say that if any one will show me the occlusal surfaces of the teeth, I will tell him whether there is pyorrhea and where the pockets are; on the other hand, if I see the pockets, I can tell how the occlusive surfaces are worn. In every case, absolutely and inevitably that condition is a factor. It may not, however, be an etiologic factor. There is an opposite condition, the result of this continued irritation. In this inflammation which goes on around the teeth in pyorrhea, a destruction of the tissues results.

I have here a microscopic slide of a tooth which is characteristic of that class. Such cases are usually accompanied by great pain. It is true in many instances, more than are realized, that pyorrhea is the cause of chronic neuralgia. There is very little pain in pyorrhea except from some of the symptoms which become complicated. It is a slow process, a gradual liquefaction and destruction of the tissue.

Dr. M. I. Rhein, New York—The various papers of this symposium which I have heard have given me personally more satisfaction than any discussion of this subject I have ever listened to at any gathering. The fact, that we have been able to listen to a series of papers which recognize the constitutional variety of exciting causes that may produce autointoxication is a point gained for which this section ought to very heartily congratulate itself. My own position in regard to this matter is very well known to most of the members. As far back as 1894, before the American Dental Association at Old Point Comfort, I introduced an etiologic classification of the exciting causes of interstitial gingivitis or pyorrhea alveolaris, and the classification I gave there is one that has been closely followed to-day by various papers, especially by Dr. Talbot, and in the constitutional treatment as outlined by the very admirable paper from Dr. Salisbury, who practically follows in the line of the etiologic conclusion I presented on that occasion. I feel more than gratified to see so much unanimity manifest at this meeting on this point. It has long been evident to me, that a symptom of various systemic disorders can not be discussed intelligently, unless that scientific point is reached, so that when an isolated case is discussed the etiology of the particular case is brought out, and an attempt is not made to have a universal panacea for the treatment of a symptom that may arise from many different causes or follow many different diseases. I have been intensely interested in Dr. Salisbury's line of thought. I believe this paper one of the most valuable presented at this meeting. I do not wish to say anything against the criticism Dr. Brown has presented in regard to too much materia medica in constitutional treatment, but so long as the acute stages of a trouble are met and they have to be treated, there must be more or less reliance on the pharmacopeia for alleviating the acute manifestations. In regard to the local treatment, I wish I had the time to go into the matter at greater length. There is a point Dr. Talbot raised about the application of iodin, and the preliminary diagnosis of the general condition of the patient. It is one in which I heartily and thoroughly coincide, more especially in the value to be obtained in forcing the iodin down into the alveolar socket itself, not only in the peridental membrane. I would say that for that purpose I have put the greatest trust in using a saturated solution of iodin with cataphoresis, using the negative pole in order to force it through the tissues. In this way I have obtained the same constitutional conditions and diminished the inflammatory, so necessary before active operations are undertaken. It is my firm conviction that if such conditions are properly treated it is necessary to give more attention to the local condition. I refer now to the keeping in absolute hygenic condition all the teeth of our patients. For my part, I have found it impossible to give the time necessary, and I have for years trained a female assistant, who devotes her entire atention to the cleansing of individual teeth. I agree thoroughly in the idea that only one, or two, or three teeth ought to be cleansed at a time, and not attempt to cover too much surface. Following this method, I feel at the present moment that my patients can have their mouths kept in the hygienic condition all the teeth of our patients. For my part, only if sufficient dental attention is given. I can not imagine any one present who is able to take the time which is necessary to do this work effectively. I throw this suggestion out for the benefit of those who have not already adopted such a plan. I am able to keep a young woman busy at nothing else but this one particular thing, and she has trained her fingers so well in this that I have many of my friends, my professional colleagues, come to her for this work because she has become so adept with an experience of seven or eight years.

DR. E. S. TALBOT, Chicago—Dr. Brown brought up one point not down on the program, and that is natural absorption. I believe that in the evolution of man the absorption of the second set of teeth is in accord with the process. In the lower vertebrates there is a succession of teeth. When one set has done its work it is lost and a new set takes its place; this continues throughout the life of the animal. Advance in evolution finds man with only two sets of teeth. Natural absorption takes place in every individual. This absorption is called osteomalacia. It takes place in the lower animals such as carnivora, monkey, horse and cow. The alveolar processes being transitory structures, disease of any kind due to trophic changes is liable to produce absorption. This may take place in children as young as 12 years, as I can prove by photographs and skulls in my possession.

DR. G. V. I. BROWN, Milwaukee—If the teeth came together so that there would be no motion, there would be comparatively little pyorrhea. When the occlusal surfaces are such that there must be a slight adjustment of the position of the teeth, every time the mouth is closed, the slight movement constantly repeated causes inflammation and a series of disturbances which develop the disease.

DR. J. H. SALISBURY, Chicago—Dr. Litch stated that he had difficulty in getting his patients to drink the amount of water Dr. Talbot prescribed. That may be due, in some cases, to the fact that the water is retained in the stomach, and so causes disturbance. Absorption of water from the stomach is practically unnatural, and if for any reason the stomach does not empty itself water will remain there and give more or less trouble. That failure to empty itself is due to the fact that the intestines are full. In that case it would be desirable to see that the intestines are emptied at proper intervals. Constipation in some cases may be the cause, or in other cases it may be due to dilatation of the stomach and causes which prevent the passage of liquid from the stomach to the intestines.

The criticism raised in regard to the continued use of drugs arose from a misconception. The continual use of drugs was not advocated. It was not at all necessary to use them but for the purposes of arousing the various organs to activity; as for instance, to empty the intestines a cathartic or two or three doses would be very desirable, but in general natural means to stimulate the powers of the system should be depended on, rather than the action of drugs. As a general practitioner, I am much interested in this question, not only from the standpoint of etiology, but also from the impression that it is a matter of vital importance. The profession should understand the possible deleterious effects upon the general system of a continued swallowing of food and mucus laden with pathogenic organisms derived from the teeth. Both the medical profession and the laity should be impressed with the very serious importance of attending to this matter, that no very serious changes take place in the stomach, and consequently in the blood.

CEREBRAL LOCALIZATION.*

SYDNEY KUH, M.D.
Professor of Diseases of the Nervous System, Post-Graduate and Medical School; Attending Neurologist, Michael Reese Hospital; Fellow, Chicago Academy of Medicine, etc.
CHICAGO.

Fifty years after Gall had published his doctrine of cerebral localization, the scientific medical world still believed with Flourens that "not only did all perceptions, all volitions, all intellectual faculties, reside exclusively in the brain, but that all faculties occupied the same place in it. That as soon as one of them disappeared from a lesion of any one point of the brain proper, they all disappeared; that as soon as one returned after the healing of that lesion, all returned. That the ability to perceive and to will, therefore, constituted essentially but one faculty; and that that faculty resided essentially in a single organ." Again fifty years had elapsed and a chart of the surface of a brain could be fitly compared to "a political map of Germany at the end of the seventeenth century." So greatly has our knowledge of cerebral localization advanced in those years that it seems impossible to give more than a most cursory review of what is known, in the course of one evening. Many important and interesting theoretical considerations will necessarily have to be neglected entirely.

We will begin with cortical localization, that part of our subject which is probably of greatest importance from a clinical point of view. The region of the surface of the brain which has been studied most carefully, and about which we consequently know most, is the motor, or Rolandic, area. That portion of the brain which lies anteriorly to this, the so-called prefrontal region, appears to be the seat of the highest mental processes. Its destruction is said to annihilate the power of directing one's attention entirely when the lesion is bilateral, while a unilateral lesion often causes only a transitory mental change. Mental weakness, loss of memory and attention, apathy and childish behavior are common symptoms. A tendency to indulge in rather stupid jokes, the "Witzelsucht" of German authors, is supposed to be particularly characteristic. In irritative lesions Flechsig claims boundless delirium of grandeur and its reverse in the early stages, later on complete apathy and loss of judgment to be particularly frequent. Bruns has taught us that pathologic processes in this region may cause ataxia of the so-called cerebellar type.

Before we enter into the study of the motor region of the brain a few general remarks about cerebral centers and brain palsies may not be out of place. These so-called centers are in all probability not mathematical points, nor even spaces with sharp boundary lines, but rather diffuse areas which perhaps differ somewhat in extent in various individuals. It is, of course, known to all of you that each hemisphere influences in the main the muscles of the opposite side of the body, a point to which I shall return presently. Some centers, however, control muscles on both sides of the body equally, such as the orbiculares oculi, the muscles of mastication, of the larynx, pharynx and to a lesser extent some other ones. Irritative lesions in these may, therefore, cause bilateral spasms, while paralysis is found only when the center is destroyed in both hemispheres of the brain. In older literature there are quite a large number of cases recorded in which spasms or paralysis were found on the same side as the brain lesion. Nasse has collected no less than 58 of them, but on account of the unsatisfactory histories and uncertain methods of microscopic examination they are of very doubtful value. There are, however, some more recent observations to which these objections do not apply. One of these I had occasion to watch for some months; it was later published by Dinkler. Here, an immense tumor had destroyed practically all of one hemisphere, and it was in all probability the pressure upon the opposite hemisphere which was responsible for the existing spasms.

---

* Read at the joint meeting of the Chicago Medical and Neurological Societies, March 7, 1900.

Another instance of even greater interest is that reported by Dr. Bidon and quoted by Charcot and Pitres. In this case there was hemiplegia affecting the left side of the body, with complete motor aphasia. The postmortem showed softening of the lower half of the left Rolandic area and the foot of the third left frontal convolution, and the microscopic examination revealed secondary descending degeneration in the left cerebral peduncle and the left anterior and lateral columns; there was no trace of decussation of the pyramids. That cerebral centers may migrate from one side of the brain to the other was at least made probable by an observation of Oppenheim. His patient had been right-handed up to the age of 17, when an injury to the right hand compelled her to learn to write with the left one. When at the age of 59 a tumor developed in the right hemisphere, it caused left hemiparesis with aphasia. Bramwell has reported a somewhat similar case in an old man.

Since the so-called psychomotor centers are distributed over a relatively large area of the cortex supplied by a number of small arteries, superficial lesions cause monoplegias more often than hemiplegias. On the other hand, monoplegias due to destruction of the white substance of the brain are rather rare, a point which may at times be of considerable value in determining the exact location of a pathologic process.

Cerebral hemiplegia, whether it be due to a superficial or a deep-seated lesion, never means a complete paralysis of one-half of the body. Those muscles which we habitually use together with the same muscles of the opposite side are affected only to a slighter degree. Thus we find paralysis of arm and leg, together with paresis of the lower part of the face, slight weakness only in the muscles of the tongue and trunk, excepting the trapezius, and no demonstrable loss of power at all in the muscles of mastication, articulation and those of the eye. Since we use both legs simultaneously more often than both arms, the weakness is usually more pronounced in the former than in the latter. Paralysis of cortical origin is flaccid in the beginning, and presents late contractures due to secondary degeneration in the pyramidal tracts.

We will next consider the distribution of motor centers in the so-called Rolandic area, which extends over both central convolutions and the paracentral lobule, to a lesser extent into the frontal convolution and the superior parietal lobule. The muscles of face and tongue, and probably also those of mastication, are represented in the lower portions of both, principally the anterior, central convolutions. The upper extremity occupies about the middle one-third of these same convolutions, extending further up anteriorly than posteriorly, while the upper one-third, as well as the paracentral lobule, and probably part of the superior parietal lobe, control the movements of the lower extremities. Experiments on animals, in part verified by clinical experiences, have taught us a great many details, which you will find on charts in any modern text-book on nervous diseases. I shall mention only a part of the more important ones here.

While monoplegias of cerebral origin affecting only the leg are relatively rare, they have been bilateral in a rather large percentage of the cases recorded. The proximity of the two paracentral lobules explains this rather interesting observation. Charcot has claimed that tubercular lesions have a special tendency to attack the leg center. A curious fact, for which there had been no satisfactory explanation for many years, is the apparent immunity of the upper branch of the facial nerve in cerebral hemiplegia. It was thought that for this portion of the facial nerve a separate cortical center must exist, and Exner and Paneth claim to have located it in animals in the gyrus angularis. A more probable explanation for this immunity has already been given. The muscles supplied by that nerve belong to those which are generally used simultaneously on both sides of the body, and, therefore, each cerebral center very probably controls both upper facial nerves. Paralysis could, therefore, occur only when both cortical areas are destroyed. Furthermore, recent pains-taking investigations by Mirallie have shown that "in every case of cerebral hemiplegia in which the lower facial is paralyzed, the upper branch of that nerve is also affected, but to a lesser degree than the lower branches or than in peripheral facial paralysis."

The cortical center for the muscles of mastication has been located in a number of animals, the dog, ape and rabbit, but, as far as I am aware, there are no clear cases in the human being on record to verify these observations.

The same applies to the center for the rotation of the head. We know where to find it in animals, but are uncertain about its exact location in the human brain.

The cortical center for the larynx was first demonstrated in cats by Ferrier in 1873. His conclusions were confirmed by experiments made on dogs by Soltmann, Krause and Duret, and on apes by Masini and Semon and Horsley. It is in all probability bilateral in man, and located at the lower end of the Rolandic area, in the immediate neighborhood of the centers for speech and face. Cases in the human being verifying these experiments are very rare, and, therefore, one which I have under observation at present may be of some interest. The patient is a man, 45 years of age, who had been ill for one week when he first consulted me. He complained of headache, and stated that about every half hour he had a peculiar attack, during which he suffered from "sticking pains" and a "shaking sensation" in his throat, and was unable to utter a sound. The examination of the central nervous system revealed no objective signs of disease, but there was marked enlargement of all superficial lymphatic glands. At that time the patient denied syphilitic infection, but later acknowledged that it occurred about one year ago. Two laryngologists examined the patient, and could find nothing to explain the laryngeal spasms, from which the patient evidently suffered. He was put on iodid of potash, and after about one week reported that he was worse. I then for the first time could witness one of his attacks. It consisted of a marked laryngeal spasm, followed by aphasia, which lasted but a very few minutes, but recurred frequently. He was sent to the Michael Reese Hospital, and there developed clonic spasms of the right side of the face, which usually followed the laryngeal attacks and a more permanent motor aphasia. Dr. Hale, who kindly examined the fundus for me, found optic atrophy on both sides. Under vigorous antisyphilitic treatment he improved considerably, was discharged, but returned after about two weeks, complaining of weakness in his right arm. This gradually increased and spread, until now the patient has a right hemiplegia with complete motor aphasia, which does no longer yield to antisyphilitic treatment. He is sinking rapidly, and will probably die within a week or so.[1]

While we are discussing the centers controlling the voluntary muscles of the body, it may perhaps be opportune to say a few words about that most important group of symptoms due to cortical lesions, Jacksonian epilepsy. It appears that quite a number of physicians even to-day consider every localized spasm of an organic nature to be cortical. That is certainly not correct.The true Jacksonian epilepsy is characterized by a number of features which occur but very rarely when other parts but the cortex are irritated, so that if we only know what constitutes an attack of Jacksonian epilepsy we will seldom err in basing our localization upon its presence. The convulsion proper is almost always—Grasset even claims invariably—preceded by a brief tonic spasm, then we see a series of clonic contractions, beginning in an isolated group of muscles, to which it either remains confined, or else it spreads progressively to adjoining groups of muscles, or may involve all of one-half of the body, or even become generalized. The convulsions hardly ever last more than five minutes, and are followed in the part first affected by a feeling of great lassitude, or even by a paresis, which latter persists for some hours, a few days, rarely for a longer time. With each successive attack this paresis becomes more intense and lasts longer; in rare cases we see post-epileptic contractures. The convulsive period is followed in the more severe cases by post-epileptic stertor, or sleep, usually shorter in duration than in so-called idiopathic epilepsy. Other post-epileptic symptoms are delirium, headache, amnesia, vertigo, vomiting, transitory aphasia, hemianopia or myosis. The sensibility usually remains intact. In rare instances, particularly when a syphilitic lesion causes the attacks, we find patches of anesthesia, most commonly on the dorsum of the hands, the outer side of the hips or the forearms. Charcot, Bourneville and others have reported cases in which the spasm consisted of tonic contractions only.[2] A glance at a chart in your text-books will show you in what way Jacksonian epilepsy may spread. The following sequence is most often seen: Face-tongue, face-arm-leg, arm-face-leg, leg-arm-face. The spasms could never jump from face to lower extremity without affecting the arm also, as the center for the latter lies between those of the two former.

Just as in idiopathic, we at times see epileptic equivalents in the Jacksonian form of epilepsy, which may either alternate with the convulsive attacks or may take their place altogether. One case of the latter type, which I saw some years ago, I referred to briefly in a discussion on epilepsy last year. Here, attacks of visual hallucinations were the first sign of a brain-tumor. In other cases these equivalents consisted in attacks of vertigo, so-called "absence," hallucinations of sight, hearing or of the olfactory sense, localized parethesiæ or sudden, impulsive acts. Attacks of migraine ophthalmique have been described; according to Féré they consist of two phases, that of excitation, in which violent circumscribed headache, vertigo, vomiting, convulsions, scintillating scotoma are noted, followed by a period of exhaustion, comprising hemianopia, somnolence, and at times aphasia and hemiplegia.

Such attacks are, as I have already stated, very rare, excepting in cortical lesions. They have, however, been seen in disease of the centrum ovale, the internal capsule, striated bodies and optic thalamus. They occur most frequently in limited lesions, which develop actively and progressively, such as neoplasmata, encephalitis or meningitis. It is not necessary for the pathological process to have its origin in the motor area proper, or even in its immediate neighborhood, as long as it causes irritation of those parts. The existence of paresis, or paralysis, makes it probable that the motor region proper is affected; absence of loss of motor power that the lesion is either very superficial or only in parts near the psychomotor centers. The early occurrence of headache points to a disturbance near the surface—irritation of meninges—a sign of considerable practical importance.

The points which are valuable in differentiating Jacksonian from idiopathic epilepsy are the following: The spasm is limited in the beginning of the attack; loss of consciousness occurs late, if at all; the epileptic cry, fall and biting of tongue are usually absent; the post-epileptic coma is slight, of short duration or entirely absent; in the so-called *etat de mal* there is no rise of temperature; finally the history of the case, in particular the age at which the first attack occurred.

Common or tactile sensibility is supposed by some authors to be localized in the psychomotor area. Some even go so far as to claim that destruction of these parts does not cause any disturbance of motility primarily, but only in so far as disturbances of sensibility interfere with the voluntary use of our muscles. Others again claim that the motor and sensory centers are distinct and separate. One of the latter group, Ferrier, has collected 284 cases in which paralysis was caused by cortical lesions, and has found that in 100 of these nothing was said about the condition of sensibility, that in 121 it was found intact, and in the remaining 63 affected. Counting only those cases in which the condition of sensibility is mentioned—and it seems extremely probable that in some of the first 100 it was not mentioned, because intact—we would find it normal in about two-thirds of all cases. Where anesthesia does exist, it often does not correspond in extent to the area of paralysis, and is usually more transitory. This has induced Charcot and Pitres to conclude that in most cases of anesthesia with cortical hemiplegia the former is purely functional, "analogous, if not identical, with hysterical anesthesia," just as we see a purely functional loss of sensibility in organic paralysis of spinal or peripheral origin. (Erb's case of progressive muscular atrophy, Gowers' case of peripheral facial paralysis, etc.)

Goltz has found that in dogs even the ablation of an entire hemisphere causes only hypesthesia, not anesthesia, and he himself admits that this may possibly be due to destruction of fibers below the cortex.

Horsley found that when parts of the motor cortex were removed in man slight loss of tactile sensation, difficulty in localization stimuli, and loss of muscular sense resulted. Most authors, I believe, concede that the latter, the muscular sense, is most intimately associated with the Rolandic area, but it can not be denied that even it may remain intact when the cortex is destroyed by disease. Ferrier has sought for another localization of common sensibility, and claims to have found it in the hippocampus major and gyrus fornicatus. Observations in the human being, tending to prove the correctness of his views, are not known to us. The entire problem of cortical localization of sensibility, you see, still remains to be solved.

---

[1] The patient has since died. No additional symptoms of any importance developed, excepting that just before death the temperature reached 108. Unfortunately we could not make a post-mortem examination.

[2] Other types of epilepsy may of course occur in cortical lesions, but they are not characteristic

One of the clinically most important centers of the Rolandic area we find in the posterior of the third left—in right-handed persons—frontal convolution, the seat of the faculty of articulated speech. Its destruction deprives the individual of the power of speech, with conservation of the faculty to understand, read and write. Broca is generally thought to have discovered this important fact, while in reality he was only one of several, each of whom contributed his share. When he published his first "memoire" he did not, apparently, know that this center was found in the left hemisphere only, a fact which had been noted by Dax twenty-five years before; but the most important work of the latter had been noticed by few, so that Broca received all the credit. In about the same region, as nearly as we can locate it to-day, is the center for musical expression, which, however, may remain intact in cases of motor aphasia. Lesions in the second left frontal convolution probably cause agraphia, i. e., loss of the memory for written images. On account of the proximity of this center to Broca's convolution, motor aphasia and agraphia are very often found in the same case.

Some authorities have claimed to have found other centers in the motor area, but their observations are all lacking convincing confirmation. Thus, Herrington claims to have located a center for the contraction of the sphincter ani in the paracentral lobe, while an area controlling movements of the bladder is supposed to be located in the front part of the gyrus sigmoides. According to Raudnitz, stimulation of the vasomotor centers in the Rolandic region decreases the temperature in the corresponding extremity, while destructive lesions cause the opposite effect.

Unverricht and Preobraschewsky claim to have found a center controlling respiration near the fissure which separates the second from the third frontal convolution.

About the symptoms caused by disease of the cortex of the insula we know practically nothing. Perdrier states that they consist in paralysis of arm and leg, without involvement of face or trunk, that the paralysis is very much more marked in the upper than in the lower extremity, that it is flaccid, without contractures, is neither accompanied by disturbances of sensibility, nor by any characteristic changes in cutaneous or deep reflexes.

Parietal lobe.—The most important portion of this lobe is the gyrus angularis. It appears to have some relation to our visual apparatus. Irritative lesions occasionally give rise to optical illusions or flashes of light, followed by temporary amblyopia, while destructive pathologic processes, more particularly in the left hemisphere, usually cause word-blindness. Bruns calls attention to the occurrence of hemi- or mono-ataxy in lesions of the parietal lobe and believes with many other observers that this part of the brain is intimately associated with the muscular sense.

It is possible, though not proved definitely, that centers for the movement of tne eyeball and upper lid may be in this region. Charcot and Pitres publish an interesting case in which a small focus of superficial hemorrhagic softening in the inferior parietal lobe caused ptosis. But Surmount has collected 61 cases of disease in the parietal lobe, in only 11 of which ptosis had been found. Conjugate deviation of the eyes and the head is also supposed in some instances to have been due to lesions in this region. But it is a rare symptom, occurs most frequently in cases of general meningitis, and is usually transitory in hemiplegias, so that we have few data for definite localization. It may also occur in disease of the mesencephalon. When it is cortical in its origin, the patient is said to look toward the convulsed extremities in case of irritation; at the lesion, in case of destruction, a law which is exactly reversed in case the mesencephalon is affected.

The cortex of the occipital lobe contains the visual centers. Their exact location is still somewhat doubtful. The symptoms characteristic of cortical lesions in this region are the following: The visual disturbance is homonymous, there are no ophthalmoscopic changes—unless due to increased cerebral pressure—the pupilary reflexes remain intact, even if a pencil of light be thrown upon the blind half of the retina only. Visual hallucinations or scintillating scotoma frequently precede or coexist with the hemianopia. It is claimed by some that in the occipital lobe are to be found the psychomotor centers for the eye-muscles and that lesions limited to its anterior portion may cause color hemianopia.

In the temporal lobe we find the auditory centers. Destruction of the left superior temporo-sphenoidal lobe causes loss of the auditory images of words, word-deafness; destruction of both temporal lobes total deafness, while irritative processes in the superior temporo-sphenoidal gyrus often give rise to auditory discharges and subjective auditory sensations, so that a spasm which begins with an auditory aura always suggests that localization.

On the lower surface of the brain are supposed to be centers of the olfactory and gustatory senses, on the region of the gyrus uncinatus. Whether the fibers preceding from them cross or not has not been ascertained definitely; for those of the sense of smell it seems very improbable.

If the large mass of white matter under the cortex is the seat of disease there may either be no focal symptoms at all, or else those of a cortical lesion or of one in the internal capsule, according to the seat of the pathologic process. Jacksonian epilepsy, however, is but rarely met with.

In the capsula interna motor and sensory tracts lie closely together, so that hemiplegia and hemianesthesia must occur in extensive lesions. The order of representation of movement is from before back: opening and turning of eyes, opening of mouth, turning of head and eyes simultaneously, turning of head alone, moving of tongue, of angle of mouth, of shoulder, elbow, wrist, fingers, thumb, hip, ankle, knee, hallux, toes. Back of the motor tracts are the fibers conducting sensibility. The group of symptoms which is characteristic for disease of the internal capsule is hemiplegia with hemianesthesia including hemianopia, but without disturbance of the pupilary reactions to light. This hemiplegia differs from that due to cortical lesions in this, that the loss of sensibility is often not only more pronounced, but also more permanent, that all qualities of sensibility are usually affected and that all of the mucous membrane with the exception of part of that of the eye may be anesthetic. Hearing, smell, taste often suffer as in hysteria. Post- or pre-hemiplegic hemichorea or hemiathetosis are almost pathognomonic of disease in this region. Grasset has also observed hemiataxy. In most of the cases in which intense neuralgiform pain occurred on the paralyzed side, the internal capsule or its imediate neighborhood was the seat of the lesion.

About the functions of the optic thalami but little is known. They are supposed to control to some extent mimic expression; so that destructive lesions would cause loss of this function, while irritative lesions may cause spasmodic crying and laughing, particularly if situated in the anterior portion of this ganglion. In most cases the symptoms will be about those just described for disease of the internal capsule and due to involvement of these paths: hemiplegia, hemianesthesia, hemichorea, etc. A very pronounced atrophy of paralyzed muscles, developing rapidly with quantitative and qualitative changes in their reaction to the electric current, was supposed by some to indicate trouble in the optic thalami, but the same phenomena have been seen in disease of the cortex.

Destruction of the striated bodies causes no focal symptoms as far as we know. These ganglia are said to contain thermic centers, but as there are some in other parts of the brain, we can not utilize this fact in localizing.

The diagnosis of a lesion in the corpus callosum is also usually impossible. The following signs are supposed to be of some importance in case of tumor:

1. The existence of symptoms of an organic cerebral trouble which develop slowly and increase constantly in intensity.
2. Hemiparesis, usually combined with more or less weakness of the opposite side of the body.
3. Very pronounced dementia, which contrasts strikingly with the insignificance or total absence of the so-called general symptoms of tumor—headache, vomiting, convulsions, optic neuritis.
4. Existence of dysarthria.
5. Absence of any symptoms suggesting any other localization.

Of these diseases which may affect the lateral ventricles directly we can recognize with some degree of certainty only hemorrhage. Its onset is naturally very sudden and violent, the coma is very profound from the beginning, convulsions and contractures are frequent, while paralysis is in some cases entirely absent, in others general. Vomiting is relatively infrequent. Recovery is rare; in the majority of instances the patients died within a few hours.

The symptom which characterizes disease in the region of the third ventricle is the nuclear ophthalmoplegia. The nuclei of the eye-muscles are arranged so that the cells for the ciliary and sphincter iridis muscles are placed anteriorly, those of the trochlear and abducens nerves posteriorly. If an ophthalmoplegia is bilateral and affects all ocular muscles, whether they be paralyzed or only paretic, it is almost certainly nuclear in its origin; the same symptoms may occur, but are very rare in lesions at the base. If an ophthalmoplegia is unilateral and affects all muscles of that one side it may be due either to disease in the region of the third ventricle or to some disturbance at the point at which the nerves enter the orbit, more probably the latter, and then often combined with some degree of exophthalmus.

The cerebellum is relatively often the seat of disease. Tumors, particularly tubercles, are often met with in children, and sarcomata and cystic growths are not at all rare. The most important topical symptom is the so-called cerebellar ataxy, a peculiar reeling gait, closely resembling that of an intoxicated person, with a tendency to fall toward the affected side. Another form of disturbance of co-ordination has been seen in some few cases of cerebellar lesions, an ataxy which differs in no way from that of tabes. Second in importance as a cerebellar symptom comes vertigo; it is true that a disturbance in almost any other part of the brain may cause this phenomenon, but in disease of the cerebellum it usually appears early and throughout the course of the malady remains a very prominent and annoying feature. Exactly the same is to be said of vomiting and headache. If a tumor, etc., affects only the cerebellum and not the neighboring parts there is no distinct paralysis, but a certain amount of weakness is often found in the extremities corresponding to the side on which the lesion is located. Some authors even go so far as to hold a paresis of the muscles of the trunk and legs responsible for the ataxy. In quite a few cases intention tremor of the upper extremities has been observed, the occipital region is often sensitive to percussion, and the knee-jerk is relatively often not obtainable. Paralysis of ocular muscles, paretic nystagmus, dilatation or immobility of the pupils, paralysis and anesthesia are very common, but they are due to pressure on neighboring parts, not to the cerebellar lesion proper. Formerly it was thought that the occurrence of cerebellar ataxy always meant involvement of the central lobe of the cerebellum, the vermis superior, but we know now that this is incorrect. I have myself seen a case in which an angiosarcoma had almost totally destroyed that part and there had never been any indication of inco-ordination.

Lesions in the anterior corpora quadrigemina may cause associated movements of the extrinsic ocular muscles, those in the posterior bodies paralysis of these muscles, particularly of the recti superiores et inferiores. The intrinsic muscles are often intact in such cases, as their nuclei are placed anteriorly to the parts we are now discussing. Ataxy, both of the cerebellar and the tabetic type, occurs frequently, particularly in the form first mentioned and in a few instances choreiform movements have been recorded. Deafness is rather a common symptom, crossed in unilateral disease. Whether the hemianopia which has been seen, is due to disease of the corpora quadrigemina proper or to involvement of the external geniculate bodies is doubtful; the fact, however, remains that it is a frequent symptom. It is thought by some that this region contains centers which control perspiration.

Disease of the hypophysis is thought to be the cause of acromegaly, although in some cases of this disease the pituitary body has been found intact. Only recently I saw a case of psammoma of this region with stunted growth and with but very few of the symptoms which are supposed to be characteristic for this localization. They are: Pain in the frontal and temporal region, shooting toward the orbits; early involvement of both eyes in form of an amblyopia with temporal hemianopia, followed later by so-called primary optic atrophy, paralytic squint, somnolence, weakness in the lower extremities, occasionally dementia and diabetes mellitus or insipidus.

If the crura cerebri are affected we most frequently find that type of alternating hemiplegia, which is known under the name of hemiplegia alterans superior, i. e., paralysis of the oculomotor nerve on one side, that of the lesion, and of the muscles of the lower face and the tongue and the extremities on the opposite side. Ptosis is usually pronounced and often one of the first, if not the first, symptom. The intrinsic eye-muscles usually remain intact. In some cases paralysis of the extrinsic muscles of the eye has been associated with a tremor of the opposite side of the body, resembling either the intention tremor of disseminated sclerosis or that of paralysis agitans; in other instances the oculomotor nerve of one side and the contralateral facial—lower branches—have been paralyzed. Frequent micturition and incontinence have been noted in a number of cases. It is rather common to see the disease begin in one crus and spread to the other one.

Another type of alternating hemiplegia is seen, when the pons is the seat of a pathologic process. Here it is the facial on the side of the lesion and the extremities and hypoglossal nerve on the other side of the body that are affected. Paresthesia and anesthesia of the latter half of the body may or may not occur. Another form of alternating hemiplegia due to disease of the pons, but less frequent than the one just mentioned, is that of the abducens on one, of the extremities on the other side. Again, in other cases the abducens of one side and the rectus internus of the other one are paralyzed, so that both eyes are turned toward the seat of the disease. In a third, the rarest, form of alternating hemiplegia finally the trigeminus—its motor or sensory branches or both together—are paralyzed on one side, the extremities on the other. Occasionally we see trophic disturbances in the trigeminal region, such as neuroparalytic keratitis. The hearing is quite frequently affected to some degree, although complete deafness is exceptional.

It is a matter of course that various combinations of the types just described may occur and that such an alternating hemiplegia is possible only in unilateral lesions. It is needless to enter into a description of the symptoms caused by bilateral lesions; a moment's thought will show what they must be; but I might add that the nerves in the medulla oblongata are usually affected more or less, thus giving rise to the additional symptoms of bulbar paralysis, difficulty in swallowing, dysarthria, paralysis of soft palate, pharyngeal and laryngeal muscles. Among the rarer symptoms the following may be worth mentioning: Albuminuria, mellituria, polyuria, and very pronounced rise in temperature. Convulsions resembling those of epilepsy are rarely seen, but more tonic contractions, especially of the muscles of the trunk and neck are not uncommon. Choked disc usually appears very late in pontine lesions and there is but little disturbance of the intellect.

The medulla oblongata contains the nuclei of the ninth to twelfth cerebral nerves, sensory, motor and vasomotor paths and centers controlling the actions of heart and respiration. Hence lesions of this part cause partial or total deafness, paralysis of the soft palate and of the larynx, of the vocal cord, disturbance of cardiac action and of respiration, paralysis and atrophy of the tongue with dysarthria and paralysis of motility and sensibility in the extremities. Since the nuclei of these cerebral nerves are mostly placed close together near the median line, unilateral paralysis or alternating hemiplegia must necessarily be infrequent. Diabetes mellitus, polyuria or albuminuria are common.

This is rather a hasty and incomplete review of what is known of cerebral localization. I would add but one point, and that is in attempting to localize a lesion in the brain we should always be prepared for surprises. I have mentioned a few of the curious cases I have seen, such as the case with convulsions on the side of the cerebral tumor, the tumor of the hypophysis with stunted growth, and as a warning to those who would still be too confident of our ability to determine the seat of brain-disease would say that I have seen typical Jacksonian epilepsy on the same side of the body in which the disease was located in an abscess of the cerebellum.

Death-Rate of British Capitals.—According to *The Lancet* the annual rate of mortality in London during the four weeks preceding July 28 was 16.2, in Edinburgh 17.2, and in Dublin 19.4 per 1000.

MEDICINE AND MEDICAL MEN IN THE UNITED STATES.

A. JACOBI, M.D.
NEW YORK CITY.

(Concluded from page 431.)

It is hardly necessary to say that for those of you for whom the practice of medicine is not only diagnosis and autopsy, but the treatment and cure of the patient in whose behalf a consultation is to be held, when medicinal treatment is in question you can not agree with a homeopath who is a Hahnemannian; and you do not want to meet a homeopath, who, because the name is still fashionable and for a portion of the misinformed public the subject of an almost religious fanaticism, employs that title for meretricious purposes. Still there are cases in which it would be inhuman to refuse a consultation in an urgent case.* Not only were such consultations held from olden times, but even in large cities, exceptions to the rule were always frequent, indeed too frequent in my opinion. Moreover, whoever is acquainted with smaller cities and villages, where a homeopath is the only rival or companion of the regular physician, knows that for either it would be suicidal to refuse a consultation. Only lately one of the medical men most widely known for his wisdom, in the AMERICAN MEDICAL ASSOCIATION and in the profession at large—Dr. S. C. Busey of Washington—proclaimed that the rule forbidding such consultations should be so modified or explained as to permit them in cases of emergency. This is exactly what the Medical Society of the State of New York made its official policy in 1882. We considered it more honest to admit by law what was constantly being done, and to decree precisely, that for reasons of humanity and in an urgent case a consultation should not be refused. For this sin we, the body of the Medical Society of New York, were expelled from the AMERICAN MEDICAL ASSOCIATION. You see we have in America our persecutions for heresy, when we have not even the recognition of religions in our constitution. It was in their names only that auto da fés were held and the bodies of men were burned. In these eighteen years, however, the animosities have not died out. You see we are a people of surprises, and have not yet found out our equilibrium. What indeed does all the discord amount to? The whole profession agrees about the inadvisability of consultations, in the very interest of the patient, with a certain class of practitioners, in the average case of illness. In emergency cases such consultations are deemed permissible for reasons of humanity by both parties of the profession. One of them bases its action on the written code of ethics, the other believes a written code to be unnecessary for its guidance. A third forms its own code of ethics, like the Medical Society of the State of Massachusetts, in 1871, and those of other states, without any recrimination on the part of the AMERICAN MEDICAL ASSOCIATION.

It is my opinion that our successors will hardly believe we ever were serious men when they learn that an enlightened and public-spirited profession could go to war over differences of motives and methods when the end in view was the same.

It would not be proper to dismiss the subject of the position of medical men without referring to them as sanitarians. It is to be taken for granted that all family physicians are sanitarians in the families they have charge of. In their societies public hygiene is frequently the subject of discussion. Practical work in that direction is evidenced by the Sanitary Commission of the Civil War, the effective labors of the New York Academy of Medicine in the reconstruction of the Quarantine Islands in the harbor of New York, and its defensive work in cholera times, the—it is true futile—efforts of all the large societies of the country in favor of the re-establishment of the National Board of Health which perished because a short-sighted Congress refused the required appropriation, and the intelligent activity under the direction of medical men, of our municipal boards of health. It is true they are hampered by the greed of politicians. Imagine that in New York the President of the Board of Health must not be a physician. Whether this is more sad or more ludicrous does not matter. The only consolation the citizens of a republic have when they contemplate such an anachronism, is that they have nobody to blame for it, and have nobody to correct it, but themselves.

But I do not wish you to believe that we American doctors are altogether angelic. Wings have not grown from our scapulæ yet. We are not such good citizens as you may believe from what I had to praise. Indeed there is no class of citizens that takes less interest in municipal, and political, other than sanitary, affairs, than doctors. It is true their vocation takes all their time and is exhausting; but the examples of European parliaments in which good medical men are representing the people, should not be lost on us. With us, however, most of the medical men in state legislatures are not the best representatives of the profession from which they claim to come, and wherever there is a medical man in the Congress of the United States, you would not know he was one unless you were told. There is at present a Senator of the United States—think of Rome and of Emilius Paulus and of Cato; of France and Arago and Nélaton; of Germany and of Virchow—who calls himself a homeopathic physician, no: a homeopathic doctor, and is the staunchest adversary of the medical profession and the solidest champion of the antivivisectionists. There is one weakness from which the medical profession of the United States does not appear to recover. In order to explain I should say that in the early [illegible] the [illegible]ies and the United States, when [illegible] and doctors scarce, the popula[illegible] domestic remedies and later [illegible]

[*It may not be inappropriate in this connection to print the following from the Code of Medical Ethics of the American Medical Association, last edition, p. 19.—ED.]

EXPLANATORY DECLARATIONS.

WHEREAS, Persistent misrepresentations have been and still are being made concerning certain provisions of the Code of Ethics of this ASSOCIATION, by which many in the community, and some in the ranks of the profession, are led to believe those provisions exclude persons from professional recognition simply because of differences of opinions or doctrines; therefore,

1. *Resolved,* That clause first, of Art. IV, in the National Code of Medical Ethics, is not to be interpreted as excluding from professional fellowship, on the ground of differences in doctrine or belief, those who in other respects are entitled to be members of the regular medical profession. Neither is there any other article or clause of the said Code of Ethics that interferes with the exercise of the most perfect liberty of individual opinion and practice.

2. *Resolved,* That it constitutes a voluntary disconnection or withdrawal from the medical profession proper, to assume a name indicating to the public a sectarian, or exclusive system of practice, or to belong to an association or party antagonistic to the general medical profession.

3. *Resolved, That there is no provision in the National Code of Medical Ethics in any wise inconsistent with the broadest dictates of humanity, and that the article of the Code which relates to consultations can not be correctly interpreted as interdicting under any circumstances, the rendering of professional services whenever there is a pressing or immediate need of them. On the contrary, to meet the emergencies occasioned by disease or accident, and to give a helping hand to the distressed without unnecessary delay, is a duty fully enjoined on every member of the profession, both by the letter and the spirit of the entire Code.*

cines. It is estimated that our people spend at present 200 millions of dollars annually on proprietary medicines; I think that this estimate is too low. Unfortunately medical men rather sustain than combat that bad habit. Our wholesale manufacturers of drugs are always busy, their agents are everywhere, their wares are dumped on the tables of the physicians of the country. The vast majority of the physicians accept them, employ them, and recommend them, and their prescriptions are frequently nothing else but the name of an American or a foreign proprietary compound. I am certain that amongst the most meritorious and instructive books of America there are none less known and appreciated than the Pharmacopeia of the United States and the Formulary of the National Pharmaceutical Association.

If there is any way to lower the regular profession and to raise and enrich the manufacturers of drugs, and drug compounds that is the way. I emphasize this, because I know from the advertisements in your journals, and from the attention paid in your articles and laboratories to proprietary stuffs of all kinds, both medicines and foods, and from oral reports of friends in all countries, that you Europeans are not much, if any, better than we; that our bad example has not taught you and that you are swamped, or about to be swamped in the cloud-burst of greedy commercialism.

Specialism is as rampant with us as it is with you. In all doctrines and branches of practice there are with us, as with you, men who know medicine and practice a specialty. But there are thousands who do not care to know medicine, but mean to make both a reputation and riches out of a limited degree of dexterity and a boundless ocean of self-assertion. That will in time correct itself, but it takes time. I trust it will disappear, if not before, when the meretriciousness of trade and industry will have found its legitimate termination in the establishment of a sounder and juster policy of human society.

In democratic communities the free will of the collective individuals takes the place of government dicta. In place of orders coming from above, rules are obeyed that are universally agreed upon by co-operating individuals. That explains the early formation of medical societies in our thinly settled country. Two were formed during Colonial times, namely, the Medical Society of the State of New Jersey in 1766, and of Delaware in 1776; in 1876 there was only one State in the whole Union that did not have a State Medical Society. Affiliated with the state medical society, and sending delegates to it, there are societies in many of the thirty to sixty or more counties of a state. The state societies as a rule meet annually, the county societies monthly, or quarterly, according to their membership, isolation and distances.

All these societies are represented in the American Medical Association, which was formed in 1847, with the exception of the Medical Society of our great State of New York, which was deprived of its membership since 1882 for a reason to which I have referred.

I should state here that the homeopathic and the eclectic practitioners of the United States are legally recognized as separate bodies like ourselves, and are similarly organized. It should also be known that there is a certain relation, legally established, between most of the state medical societies and the legislatures of their states. This legal position is not, however, possessed by the American Medical Association.

Still, the voice of that body, powerful through its numbers and the character of its membership, is frequently raised in connection with public questions. So is that of other large societies. The New York Academy of Medicine, for instance, has often advised and coöperated with official bodies of New York City and State, though originally it was not intended that it should exercise any such influence. Other societies which in large cities are formed for special scientific purposes, have no such influence or activity and do not claim it.

The number of medical societies in large cities has probably become too large. There are many practitioners who are members of many more than one society. Beside the legalized society of the County—I now speak of New York City—having about 1500 members, there is the "Association of the County," with about 800, and a third one lately formed—the Society of Greater New York. If our brethren would only remember that there is more strength in forceful consolidation than in fanciful expansion or multiplicity—but then, it is not always strength and harmony that some men seek, but egotistic self-assertion and envy of the success of others. Besides, we have many societies limited to certain neighborhoods on account of the great distances, and special societies such as the Pathological, Neurological, Ophthalmological, Dermatological, Obstetrical; also a large and active German Medical Society, and last, but by no means least, the New York Academy of Medicine, which I mentioned before. Let me say a few words about it, for it illustrates some of the differences between America and Europe.

NEW YORK ACADEMY OF MEDICINE.

When our New York Academy of Medicine was founded in 1847, it was well understood that it was to differ materially from what is called an Academy of Medicine in Europe. The latter is always a government institution, and in some way or other is supported by centralized national means, or accumulated funds. Its members comprise the intellectual and sometimes the social heads of the profession only. Young faces are seldom seen amongst its fellows. Membership is, as a rule, obtained after a long life of successful scientific pursuits only. Their labors and efforts are not always intended for immediately practical aims or objects, but become beneficent by the action of that logical force which ordains that there is no scientific result, no truth ever so abstruse, that will not finally terminate in some tangible application. Though all this be true, the limitation and exclusiveness of membership results in a sort of aristocratic estrangement from the masses of the medical profession, and still more from the community at large.

The New York Academy of Medicine has a broader democratic basis. The high and the lowly, the old and comparatively young, the mature and the youthfully ambitious combine for the same purpose. The Academy is not connected with any school or college. It is self-supporting, and is carried on in the interest of the whole profession, whether members or not. There are no fees or emoluments of a private or individual nature. It is a democratic community, with equal duties and rights. It is not subsidized by the state or municipal corporation. Its aims are the elevation of the profession to a higher scientific standard for increased public usefulness. Having been a member for forty-three years, I have known it when it was small, and followed its growth with grateful and hopeful eyes until it was established in its present palace, with its ever-increasing public medical library, second in size and importance in the country; its absence from medico-political fights about the advisability or superfluousness of a written code of ethics; its impartial and non-political interest and co-operation in all public sanitary questions; its labors in matters of quarantine, cholera and watershed; its generosity to members and non-members alike; its rooms taken up by many large and small special societies so as to form the medical center of the metropolis; and its ten sections in constant working order. These have given the young and deserving men, during more than a dozen years, the opportunity for legitimate competition, for obtaining a hearing and making their reputations, which are due—next to themselves and their honest work—to the New York Academy of Medicine. Ask me, for a medical institution, democratic, enlightened, independent, generous, and progressive, the daughter of a country free, independent, progressive, and in spite of the present plutocratic clouds overhanging its clear democratic sky, the hope of future mankind, and I shall give you the name of the New York Academy of Medicine.

SOME FACTS ON MEN AND INSTITUTIONS.

During the time of the War of Independence there lived Bard, whose papers on diphtheria are to-day examples of good observation and elegant diction; and Rush, one of the signers of the Declaration of Independence, a fertile writer and famous teacher; a little later Dunglison the lexicographer, Drake, the author of the "Diseases of the Mississippi Valley," and Mitchell; then men like Wormley, whose "Microchemistry of Poisons" appeared in 1867. Contemporaneously there was Bigelow, the inventor of litholapaxy, and Oliver Wendell Holmes, who wrote on the contagiousness of puerperal fever in 1843; then came Harry P. Bowditch, Meigs, Clark, Flint, J. W. Draper and Beard. Remember, I speak of the dead, of some of the dead, only. Of modern times I shall mention no names, but the many studies on malaria, amebæ, blood, and diagnosis in general, commend themselves to the studious expert. The literature of these few generations is very fertile; even smaller men did meritorious work. In 1835 it was Fisher of Boston who discovered the fontanelle murmur, and in 1832 it was a country doctor in Canandaigua who gave the first plausible explanation of the crepitant râles of incipient pneumonia. What should always be remembered is this, that all the men I mentioned were engaged in the practical work of their profession; and that some of them had enjoyed no other instruction than what the insufficient schools of the country could furnish.

Thus it appears that no faulty system of teaching, no defectiveness of schools, hamper a man whose stimulus is necessity from within, and an ideal. Sometimes this alone is sufficient for unusual results. Think of Marion Sims, and, in spite of his insufficiency as a pathologist, of the impetus his genius gave to gynecology.

But this is not what is best known in Europe about us. We are principally credited with the introduction of anesthesia into practice.

Dr. Long, of Jefferson, in the State of Georgia, removed a tumor under ether. But it was a dentist, William Jennings Morton, who successfully gave ether to a patient on whom Dr. J. Collins Warren operated for a tumor, in the Massachusetts General Hospital in Boston, on October 16, 1846. Before this assembly of medical and laymen I confine myself to what Lecky says in his "History of European Morals": "It is probable that the American inventor of the first anesthetic has done more for the real happiness of mankind than all the philosophers from Socrates to Mills." Nothing remains to be said, except that not only was the discovery made in America, but even the name anesthesia was coined by an American, Oliver Wendell Holmes, great as an anatomist, as a physician, a poet and a scholar.

Our perfect ambulance system has been largely imitated in Europe, and to a small extent also, the night medical service for the poor.

Thus, for the humane purposes of medicine you admit America exhibits a good record; in many other respects it does not excel, but equals Europe. Its hospitals, and operating rooms are like yours, many I have been told are better than yours. There is no country in which the demands of antisepsis and asepsis are more scrupulously obeyed than ours. The medical attendance on hospitals, however, is capable of improvement. In Europe a distinguished man is known for his lifelong connection with a special hospital. That is less so with us. The ambition to be on a hospital staff, the democratic tendency of the authorities to be fair to the greatest possible number, are the reasons why the hospital staffs are unduly large, and the year is divided up in alternating temporary services, and men are compelled, in order to have hospital services through the whole year, to seek them in different institutions. The improprieties and drawbacks of this arrangement have so long been felt that the establishment of permanent services, mostly of a special nature, has been resorted to in some hospitals. One particular disadvantage of our system of cutting up our hospital services, which you may have noticed, is that our hospitals, while a source of constant improvement to the lucky incumbents of the medical places, have not contributed to medical literature in the shape of special scientific reports, with the exception of the last few years.

The assistantships are in almost every case in the hands of young graduates who obtain their places after competitive examinations. Their terms of service range from one and a half to two or two and a half years, in semi-annual advances from grade to grade. This method affords a great many young physicians an opportunity for more or less independent work guided by their superiors who make gratuitous daily visits during their term of service. That is how the people of the United States derive immense benefit from the facilities afforded to a very large number of young graduates before they enter into private practice.

When I rose, I did not mean, nor was I expected to entertain, but to communicate facts. I spoke good and evil of medicine and the medical men of my country in order to secure knowledge and appreciation in Europe. What I briefly wrote for you could be only flashlight pictures, which, when more closely inspected, may be apt to convey some information; what I could say are but fragments; what I wished all the time was to help in relieving mutual isolation. This isolation has sometimes led to misapprehension and estrangement, but, I think, you have lost more from them than we, for our eyes were and are always directed to the East, whence we came one-half, one, two centuries ago, and where the sun rises. But it takes the sun only four or five hours to come to us, and it is the same sun. Your books are on our shelves, our students and doctors go to you to learn and to compare, and they return, and the time is fast approaching, I hope, when yours will travel with the sun to enjoy the light ot the West. In this way mutual appreciation and respect will engender tolerance and justice, and kill chauvinism. Modern chauvinism is just as much a people's overestimation of its own old methods and actual or alleged achievements as original hatred. That is why every nation is infected with it; for its cause is ignorance, owing to the narrowness of mental horizons. When vision is locked up in valleys, the sun rises late, or too late, or not at all.

Of jealous rivals, mutual appreciation makes eager collaborators. That I take to be the sacred office of international meetings. That is why, as I have done these twenty years, I gladly came and, with the approval of your officers, selected this subject, to do away with errors and misapprehensions, and aid in procuring mutual understanding and fraternity. Cosmopolitanism does not advance on parallel lines. Some classes of men, some branches of science, must be the first to force a breach. Such a class of men, and such a science is medicine, most humane, both as theoretical knowledge and applied art.

Perhaps I had an additional reason. I come from a country that at present is believed by many of us, and of you, and, I regret to confess, by myself, to be not true, at least temporarily, to its principles and its history, though all firmly believe and trust that the soul of the people is sound and its feeling is conservative.

If only the political and social development were founded on the same basis of methodical research as modern medicine! That soundness, conservatism and method in evolution I claim for American medicine. Having the great advantage of developing out of Anglo-Saxon medicine, with its sober observations and cool thinking, no Schellingian mysticism ever led it astray, and popular fads did not permanently pollute it. It never forgot that the human body is not a mechanism, but an organism, that no specialties can legitimately exist apart from medicine, that the special doctrines and studies in books and clinics and laboratories are its handmaids, but not its equivalents, that what the great American, Benjamin Franklin, said is true, viz.: That the knowledge of natural history is nothing if not applicable to some service to mankind, and, finally, that the object of medicine is always the prevention or cure of disease in man, community or mankind. That is what makes medicine, in its broadest sense, the example and harbinger of what we all should work for, the future enlightened policy of fraternal, cosmopolitan and humanized mankind.

ANESTHESIA.

COMPLETE FAILURE TO SECURE IT WITH CHLOROFORM; PERFECT SUCCESS WITH NITROUS OXID AND ETHER.

D. H. GALLOWAY, M.D.

CHICAGO.

The following case is reported as an example of the value of nitrous oxid as an aid to anesthesia with ether or chloroform:

About 5 o'clock one afternoon I was called to a suburban town to administer an anesthetic, and on arrival received the following history of the case. About 1 o'clock that afternoon, the patient, a young man, met with an accident in a factory, by which one of his legs was completely severed. The accident was such that there was almost no hemorrhage; his fellow workmen put a tight constrictor about the stump and conveyed him to the hospital. A surgeon was sent for and at 3:30 p.m. they prepared to amputate the stump. One of the physicians began the administration of chloroform, but in a moment the patient began to struggle and then ceased breathing. The anesthetic was stopped and the patient resuscitated without much trouble. The chloroform was reapplied and again the patient stopped breathing. The chloroform was removed and the patient resuscitated, and when his condition seemed normal the anesthetic was reapplied repeatedly, but always with the same result. After some time spent in fruitless attempts to get the patient anesthetized, this physician refused to continue the effort and his place was taken by another, who met with no better result. A third one then tried, and after a few trials, in which he met with the same difficulty, and three-quarters of an hour had been spent, the effort to secure anesthesia was abandoned.

On examining the patient I found his respirations rather shallow and 24 to the minute, pulse 92 and good. The pupils were greatly contracted and, although he answered questions rationally, he seemed to be in a partial stupor. I learned that he had received two $\frac{1}{4}$-grain doses of morphin hypodermically previous to the attempt to anesthetize him, and another of the same amount while awaiting my arrival. I began the anesthesia with nitrous oxid gas; in 30 or 40 seconds the patient was unconscious, ether was substituted and in two or three minutes he was profoundly anesthetized, and in five minutes the operation was begun. The patient did not move a muscle or utter a sound, and the amount of ether necessary to maintain anesthesia was less than half the amount which is usually required. Pulse and respiration did not noticeably change during the continuance of the anesthesia—fifty minutes.

The trouble with the chloroform was doubtless due to the large dose of morphin, to which he seemed to be abnormally susceptible.

THE BACILLUS OF PHILIPPINE DYSENTERY.

Extract of a Report by Assistant-Surgeon R. P. Strong, U. S. Army, and Dr. W. E. Musgrave, 1st Reserve Hospital, Manila, P. I.

The authors describe in detail the typhoid-like bacillus they found and the cases in which they encountered it, as follows:

Morphology.—Bacilli with rounded ends which differ in morphology in various culture-media. On agar cultures they generally appear as short rods with rounded ends measuring 1 to 3 microns in length and about .4 to .5 broad, occurring not frequently in pairs. In 24-hour bouillon cultures the rods are always longer, often measuring 3 or 3.5 microns in length, occurring frequently in pairs, and occasionally—particularly in old bouillon cultures or in fresh bouillon cultures made after many generations on artificial media—the rods may be seen even longer; and it is not infrequent then to observe filaments of several organisms. The organism possesses no capsule and does not form spores. No flagella have been demonstrated.

Staining Properties.—They stain readily and evenly with ordinary aniline dyes and are easily decolorized by Gram's method, but not decolorized by alcohol except by prolonged treatment. Old bouillon cultures sometimes show slight irregularities in staining.

Cultural Characters.—Anaërobic and facultative anaërobic, very slightly motile bacillus. Spore formation has not been observed. It grows on the usual media both at room temperature and in the incubator.

On agar-plate cultures after twenty-four hours in the incubator superficial and deep colonies develop. The surface colonies are round, of a distinctly bluish-white tinge and delicate, measuring from about .5 to 1 mm. in diameter; under a low magnifying power these colonies are often nucleated, having a darker center with a gradually growing lighter periphery. They are granular with often a tendency toward central radiation of the granules. These colonies are generally round with even borders. The colonies in the depth are small, more yellowish, oval or round, and present nothing characteristic.

Often from the 24-hour plate cultures, made from the stools of acute dysenteric cases, when the plates are held up to the light the colonies of dysenteric bacilli can be picked out from the colon colonies by their more delicate growth and by their bluish tinge. In older plate cultures the colon demonstrates that it is a heavier grower. From close observation of many plate cultures we have concluded that in a 24-hour plate culture certain colonies of bacillus coli communis resemble the colonies of those of bacillus dysenteriæ so closely that they can not be told apart either by the naked eye or by a low magnifiying power. On the other hand colonies of the bacillus of dysentery never resemble certain common forms of colon colonies.

On agar slants with bacillus dysenteriæ a moderately heavy growth appears after twenty-four hours, bluish-white by transmitted and whitish by reflected light. The growth is lighter than that of bacillus coli communis and sometimes even lighter than that of bacillus typhosus.

On glycerin agar the growth is about the same as on ordinary agar. In gelatin stick culture the organism grows along the track of the needle without liquefying the medium.

In glucose-agar stick cultures there is never any production of gas. The growth occurs along the track of the needle and slightly on the surface about the point of inoculation of the medium. Litmus milk is always slightly reddened after twenty-four hours. The red color does not change further and no other change occurs after one week. Ordinary milk is neither coagulated or peptonized, but appears unchanged though the organism grows well in it.

Litmus-lactose agar is apparently not changed after twenty-four hours. There is no gas formation; neither is there any fermentation in saccharose cultures.

On fresh potato cultures after twenty-four hours there is generally apparently no growth or only slight moisture about the track of inoculation; after three days there is a light straw-colored growth, which gradually becomes heavier and a little darker by the end of a week. Coverslips show that the organism grows well on this medium. In bouillon cultures there is moderate clouding of the media in twenty-four hours, with the formation of a light precipitate. No pellicle on the surface ever occurs. Dunham's solution is clouded in twenty-four hours with the formation of a slight sediment. Neither in Dunham's solution nor in Smith's sugar-free bouillon is there any indol production.

The bacillus is pathogenic for mice, rats and rabbits, when injected either subcutaneously or intraperitoneally. White mice when inoculated with one-half to one c.c. of a 24-hour bouillon culture, generally die within forty-eight hours, but may live three days. Post-mortem the organism may be obtained from the visceral organs and from the heart's blood. When the same amount is injected intraperitoneally the animal dies generally in from ten to twenty-four hours. Post-mortem there is generally edema of the abdominal walls, and a little fibrin over the surfaces of the intestines. The organism may be obtained from the abdominal cavity, visceral organs and heart's blood.

Manila gray rats, when inoculated with one-half to one c.c. of a 24-hour bouillon culture subcutaneously, generally died on the third or fourth day. The organism may be obtained from the visceral organs and sometimes from the heart's blood. When inoculated intraperitoneally with the same amount, death takes place in from twenty-four to thirty-six hours. Post-mortem there is a little fibrin over the intestines. The organism may be obtained from the liver, and generally from the spleen and heart.

In rabbits subcutaneous inoculation of 1 c.c. of a 24-hour bouillon culture generally causes death on the third day. At necropsy the vessels of the epicardium are injected; the vessels of the mesentery are also brightly injected; the gall-bladder is swollen; there are small hemorrhages in the liver; the stomach and small intestine contain a small amount of mucus. The cecum and large intestine are distended with apparently normal feces.

Intraperitoneal injection into rabbits causes death with a more marked peritonitis; otherwise the changes are the same as when the inoculation is made subcutaneously. The organism is found in greater numbers in the liver than elsewhere.

Four monkeys were fed for two weeks daily, with a 24-hour bouillon culture of bacillus dystenteriæ. Two of the monkeys were fed 10 grains of sodium bicarbonate previous to taking the bouillon culture. Three of the cases had at times a moderate diarrhea; at no time was there blood in their stools. Bacillus dysenteriæ was recovered from their stools. In the fourth case, there appeared after about ten days' feeding a little mucus and blood in the stools for two days. Microscopical examination showed the trichomonas intestinalis, red blood-cells and epithelial cells; no amebæ. Bacillus dysenteriæ was obtained from the stools. The feeding was continued, but the stools became normal, with no further result.

Cats and dogs were injected per rectum with large amounts of fresh, bloody, mucous stools from acute dysenteric cases in which the bacillus dysenteriæ had been demonstrated. No dysentery was obtained and no changes in the large intestine.

Cats were given enemas of bouillon cultures of bacillus dysenteriæ. Only slight diarrhea for a few days was produced. One cat was killed nine days after the injection; at necropsy there was no swelling of the mesenteric glands. On opening the large intestine the rugæ were seen well marked, the surface of the bowel bathed in a light layer of mucus. Microscopical examination showed only epithelium and epithelioid cells. No hemorrhages nor ulcerations of the large bowel.

Subcutaneous injection of one c.c. into a Manila pony causes a rise of temperature in the neighborhood of 105 F.; after a few days' illness the temperature declines to normal.

The virulence of the organism varies greatly in different cultures. The organism quickly loses its virulence when grown for any length of time on artificial media. Thus it will be seen that the disease, acute specific dysentery, can not be produced as such in animals any more than typhoid fever can.

We will now attempt to describe the type of dysentery which we have called *acute specific dysentery*.

Acute Specific Infectious Dysentery.—Definition: An acute infectious disease characterized anatomically by an extensive superficial necrosis of the mucosa and by hyperplasia and hemorrhagic infiltration of the lymph-follicles of the large intestine, with induration and thickening of its walls; by hemorrhagic swelling of the adjacent mesocolic glands; and often by parenchymatous changes in other organs. The bacillus dysenteriæ is present in the acute stage of the disease, both in the discharges and in the superficial necrotic layer of the intestinal mucosa. Clinically the disease is marked by an acute onset, by very frequent mucus bloody stools, accompanied by intense tenesmus and by an abrupt termination either in death—usually in from four to fifteen days—or by a gradual improvement, from which an early recovery takes place, or the disease may apparently pass into a subacute stage.

Etiology.—The disease seems widely spread over the island of Luzon, but has occurred particularly among our troops in certain districts. The cases often appear in groups. It is not the rule to find sporadic cass. In one regiment in which in the neighborhood of twenty cases of typhoid fever occurred within a short space of time, there were almost twice that number of acute specific dysentery cases within the same space of time, as verified by the clinical histories and by the blood-serum reaction. It is not possible for us to say just now if the disease is spreading to any great extent. The conditions under which our troops are living are very different from what they were last year; the troops all practically being in garrison now. The disease appears to occur more frequently toward the end of the rainy season. Thus in the latter part of July and in August and September, 1899, there were more cases which came to necropsy with this type of the disease than in the remaining nine months of the year together.

Infection.—Infection probably occurs generally through the drinking water. Milk is a possible means of infection, but not a practicable one here, owing to the scarcity of cows' milk in the Philippines, and to the little use of other fresh milk as food. Infection through uncooked food—salads, cresses, etc.—can not be excluded. Undoubtedly infection is markedly influenced—as in cholera—by the existence of catarrhal troubles, irritating food, bad food, constipation, starvation, physical exhaustion, exposure to wet, etc. Infection with malarial plasmodia can hardly be consid[illegible] importa[illegible]isposing factor, for it occurred in only [illegible] ac[illegible] only one [illegible] our subacute cases.

The Bacillus Dysen[illegible]

shown that a bacillus similar to, if not identical with, the one we have described above, is probably the cause of a certain form of acute dysentery in Japan. Our own researches seem to show that this organism is probably the etiological factor in the acute specific form of dysentery which occurs here, and which we are attempting to describe. We have isolated this bacillus from twenty-eight cases of dysentery. Nineteen of these cases came to necropsy and all showed similar lesions of the large intestine, to be described below. This bacillus was isolated in eighteen of our twenty-one necropsies on acute dysentric cases. In our first acute case it was not sought for; in the remaining two it was not found. In our subacute cases it was obtained twice out of eleven necropsies. In two cases it was unfortunately not looked for. In the other seven it was not found. We shall refer again to the difficulty in finding the bacillus in the later stages of the disease.

The organism has been sought for in normal stools, in the contents of the large intestine of those dying from other diseases than dysentery and in the feces of monkeys and rabbits, but has never been encountered on any of these occasions. In twenty-six cases of dysentery which presented post-mortem an entirely different anatomical picture of the large intestine, and in all of which amebæ dysenteriæ were present, this bacillus was carefully sought for, and never found. Lastly, the disease has been produced in man on one occasion by inoculation with this organism.

Serum Reaction.—The blood-serum of the acute and subacute cases shows usually a marked agglutinative reaction for this bacillus. The reaction may be present as early as the third day and is usually marked by the fifth or sixth. In one grave acute case which died on the fourth day of the disease, there was no reaction with the serum, either ante- or post-mortem, with this organism. The reaction may persist for several months but usually seems to disappear in a shorter time. In one case of our series it persisted for six months, but has since disappeared.

General Description.—The period of incubation probably lasts not over forty-eight hours. In one case, to be referred to later, in which a pure culture of the organism was swallowed, symptoms of the dysentery began to appear after twenty-four hours. The onset of the disease is usually abrupt; there being no prodromal symptoms generally. Often a patient goes to bed feeling perfectly well; during the night he is suddenly attacked with dysentery, and it is not infrequent for these cases to have from twenty to forty stools during the night. The stools at first contain a small amount of mucus; this mucus rapidly increases in amount, however, and soon becomes blood-streaked; generally within forty-eight hours, or a shorter time, the stools consist of nothing but reddish, bloody mucus. Microscopically these discharges consist, in the later stages, of many red blood-cells, leucocytes, epithelial cells and large epithelioid cells. No amebæ are present in unmixed infections. The movements increase in frequency until finally there appears to be no control whatever over the sphincter ani, and the patient is almost continually on the bed-pan or pad. The straining and tenesmus are often excessive. Toward the end the movements become less frequent, and may cease altogether shortly before death. Extensive hemorrhages are very unusual, but occasionally occur, always mixed, however, with more or less mucus. Excessive thirst is usually a prominent symptom. The tongue is generally coated with a whitish fur.

Fever.—The temperature is very irregular and variable, though almost always is there some pyrexia present. It may often reach 103 or 104 F., or it may not rise above 102 F. Just before death the temperature may rise rapidly, or it may fall as rapidly to a subnormal point; the latter is always a very unfavorable sign.

The blood changes are not constant; there may be a moderate leucocytosis, but in the rapidly fatal cases often the number of leucocytes is not increased. The red blood-cells in the first forty-eight hours are often increased in number, doubtless due to the early loss of water through the bowel; but shortly after the appearance of blood in the stools, notwithstanding this concentration of the blood, the blood count from the corresponding loss of red cells may fall below four million to the cubic millimeter. Differential counts show that when a leucocytosis occurs it is the polymorphonuclear variety of white cells which is increased in number.

Pulse.—The pulse in the early stages of the disease is in the neighborhood of 100. As the disease progresses, particularly in unfavorable cases, the pulse becomes very rapid and may reach 150 or more. The extremities become cold and the patient generally dies in coma, from cardiac exhaustion.

Cardiac complications are rare. Neither acute endocarditis or pericarditis has occurred in any of the cases studied. In the grave cases the sounds early become rapid and feeble and running; they soon lose their normal rhythm and approach that of embryocardia.

Nausea and vomiting are also somewhat uncommon, but occasionally occur, particularly in the earlier stages of the disease. Acute gastritis was found to be present in one subacute case at necropsy. There is often abdominal tenderness, particularly about the region of the colon, on deep pressure. No particular part of the colon appears constantly more tender than the rest. The abdomen is generally not distended. The spleen is generally not enlarged.

Respiratory System.—Pulmonary complications have been occasionally present; lobar pneumonia occurred in one subacute case, and bronchopneumonia in three acute and one subacute case. Acute bronchitis and fibrinopurulent pleurisy have been found, each once in two of the acute cases of dysentery.

Nervous System.—There is no complaint of intense headache. Delirium may occur toward the close, particularly in the prolonged fatal cases. Convulsions have not been noted in any case, nor has neuritis or paralysis been observed as a sequela.

The urine is always decreased in amount, and may contain a small amount of albumin. Retention is often an early symptom. The diazo-reaction does not occur. Acute glomerular nephritis has been found post-mortem in one case.

In none of our cases has the liver been found much enlarged or tender. It is perhaps hardly necessary to mention that liver abscess has not been found in this form of dysentery.

Recovery from the most severe form is rare; in those cases which recover, the loss of weight may be very marked; a loss in the neighborhood of 20 to 30 pounds may occur within two weeks. The patients, after the acute form, are generally left in a weakened state. After convalescence has been established, they do not seem to suffer from dyspeptic or intestinal troubles. One attack does not necessarily protect, for one of our cases writes to us from a distance that he has had a similar attack to his first, which was a severe one and studied clinically by us. The second attack occurred five months after the first, convalescence had been long established between the two. The most violent stage of the disease rarely lasts a week, although patients have lived for ten days in this stage. We have referred before to the fact that the cycle of this type is different from that of the amebic type of dysentery. In the former it is brief; thus of our twenty-one acute cases which came to necropsy, four died on the fourth and four on the fifth day of the disease. None of our cases died before three complete days of illness. Ten others died before the fifteenth day. In those cases which recover, the urgency of the symptoms gradually diminishes, the stools gradually lessen and the temperature declines. Recovery then may be early and convalescence well established by the end of the second week, or the disease may sometimes become subacute and last for months. One of our cases died on the sixty-fourth day of the disease. We regret that we have not as yet studied clinically this subacute stage as carefully as we could wish. These patients are usually poorly nourished and have thin bloody mucus stools from time to time; often not over from three to five in twenty-four hours. These stools in unmixed infections do not contain amebæ. The blood-serum of these cases shows a well-marked agglutinative reaction with the bacillus dysenteriæ, and sometimes an agglutinative reaction with certain colon bacilli; particularly for varieties of colon which show feeble power to ferment sugars, and which only faintly redden litmus milk without coagulating it, and which perhaps should be more correctly referred to as paracolon bacilli. These subacute cases with their serum reactions will be more fully described in a later paper.

SATURDAY, AUGUST 25, 1900.

MEDICAL SCHOOLS AND HOSPITALS.

Medical education in the United States has made wonderful progress during the last decade. The day of the two-year year school is gone; that of the three-year school is rapidly drawing to a close; and already we hear talk of establishing courses of medical study extending over five years of eight to nine months each. Simultaneously, scientific medicine has also reached a higher plane than ever before. Original research, new discoveries, and finished clinical and other studies are making their appearances in a manner that betokens a sound foundation, thorough training, and fully equipped hospitals and laboratories. That this progress of medicine in general is gratifying to all who have its true interests at heart, naturally goes without saying. But there is much to be done. The great majority of our medical schools fail to adequately meet the responsibilities they shoulder in offering young men and women "full opportunities" to secure a thorough medical education. The crying need at this time is greater facilities for proper clinical instruction. In this respect, perhaps, all our schools fall short, although there is a heaven-wide difference between the two extremes reached.

One of the necessities of a properly equipped medical school is a large hospital. It does not suffice that this hospital is adjacent to the college; it must be under the full and unrestricted management of the college, as far as the medical work is concerned. It should form one essential part of the machinery for giving instruction, as it is the mainstay of the college. Indeed, to a large extent the hospital, with its wards, its outpatient department, its operating-rooms, its dead-house, and its laboratories, is the medical school. All other instruction is naturally preliminary to observation and study in the hospital. The eager, intense competition on part of recent graduates for all kinds of interneships is sufficient evidence of the need the students themselves feel of further clinical training. Give a student but fair opportunities to work in the hospital and he is more than willing to spend a year or more after graduation. He asks no pay, simply a chance. Indeed, in some medical centers, the best students spend the last year or more of their medical course in the most arduous special training for the hospital examinations—a system fostered by the antiquated method of examining applicants for interneships and by the absence in the college of the necessary facilities for proper clinical instruction. The day of exclusively hearsay learning in medical schools is past.

Like the student of other biologic sciences, the student of medicine demands the chance to see and to feel with his own senses. And he should have it. But how? In the first place no medical school should be considered fully organized without a well-established general hospital under the unquestioned and permanent control of its faculty, as the first and fundamental requisite. It is high time that the state take cognizance of the opportunities for, and the character of, the practical, clinical instruction offered by the various corporations that send up graduates as applicants for state license to practice medicine. At present the state pays little or no attention to this part of the medical schools.

Secondly, the existing hospitals, city, county, and endowed, should be organized and utilized to the fullest extent. Educate the governors of hospitals and the public so that they may see that the use of the hospitals for clinical study by medical students, when rightly conducted, means improvement in the treatment of the patients and of the scientific work of the hospitals. There are neglected opportunities of clinical instruction in all our large cities. The number of interneships may be increased quite generally without detriment to the service.

In the third place, the clinical teacher should be in such a position that he would feel more his responsibilities. The clinical departments should be reorganized, and men should be placed at their head who are properly paid and of whom more may be demanded than of those who regard their clinical services merely as a means of rapidly acquiring a large private clientèle. Commercialism and clinical teaching do not harmonize. There are able young men springing up who are willing to devote their energies to scientific clinical teaching and work for a financial return commensurate with that received by scientists in other departments. This means money, and we are fully aware of the status of our medical schools in this respect. Progress, however, lies in this direction. Finally, it may be emphasized again that in order to realize for our medical students the best opportunities for correct clinical teaching, the hospital must be an integral part of the school, and as completely under its control as the chemical or other laboratory—all other arrangements are in the end unsatisfactory, temporary, and often irksome and unsafe.

THE BACILLUS DYSENTERIÆ.

Reports have been received at the office of the Surgeon-General of the Army as a result of the requirement of the Surgeon-General that a careful study of the dysentery of the Philippine Islands be made in the bacteriological laboratories of the large military hospitals. Assistant-Surgeon Strong, in charge of the First Reserve Army Laboratory, in Manila, and Hospital-Steward W. E. Musgrave, M.D., pathologist of the hospital, have reported[1] that during ten months 9063 cases were admitted to the First Reserve Hospital, and that in 1328 of these cases, or 14.65 per cent. of the total, a diagnosis of dysentery was entered. Of the dysentery cases 125 died, a mortality of 9.4 per cent., which, however, by no means represents the fatality of the disease, for 338 of the cases were transferred to the United States, as there seemed little hope of their recovery while in the Philippines, and 283 were sent to other hospitals. Only 581 were returned to military duty from the First Reserve Hospital.

The report of these officers is based on careful clinical and post-mortem observations. The anatomical changes found in 111 fatal cases of dysentery enabled them to divide the cases into two distinct types: a specific dysentery, of which 21 of the cases were acute and 11 subacute; and an amebic dysentery, which included the remaining 79 of the fatal cases examined. It is claimed that when the type of each case, as determined at the necropsy, was compared with its associated clinical history, the two types might easily be separated during life, the clinical cycle of the disease as well as the onset being generally somewhat different in each type, and while one may be recognized by its specific blood-serum reaction on the bacillus dysenteriæ, which was isolated in each case, the presence of ameba dysenteriæ in the stools is characteristic of the other.

The disease associated with the infection of the bacillus dysenteriæ is said to be characterized anatomically by an extensive superficial necrosis of the mucosa, and by hyperplasia and hemorrhagic infiltration of the lymph follicles of the large intestine, with induration and thickening of its walls. Clinically the disease is marked by an acute onset and an abrupt termination either by death—usually in four to fifteen days—by an early improvement and recovery, or by passing into a subacute and prolonged stage. In the amebic form there is, on the contrary, an irregular course, marked by intermissions and exacerbations of the diarrhea with a tendency to chronicity and the frequent occurrence of abscess of the liver.

Drs. Strong and Musgrave review the history of the bacteriology of dysentery to 1898, when Shiga, working in Kitasato's laboratory in Tokio, described a bacillus in connection with the epidemic of dysentery then prevailing in Japan. He obtained a specific organism in thirty-four out of thirty-six cases studied, which he believed to be the *vera causa* of the Japanese epidemic. The bacillus is a short rod much resembling the bacillus typhosus or the greater portion of the coli group. Flexner and Barker, who investigated the prevalent diseases of the Philippines[2], state in regard to their bacteriological results in dysentery that tests for agglutination developed two groups of bacilli, one having affinities with the coli communis, the other with the bacillus typhosus. "A bacillus," they say, "belonging to the second group, which is still under study, would seem to agree with the bacillus dysenteriæ isolated by Shiga from cases of endemic dysentery occurring in Japan. It is regarded by us as an important factor in the causation of the dysentery of the Philippine Islands." Strong and Musgrave recognize this bacillus as the cause of their specific dysentery.

Many of the cases of Philippine dysentery which were not expected to recover in the Philippine climate were sent on transports to San Francisco. Here, they were studied by Dr. Charles F. Craig, who examined the stools of 205 cases and the morbid anatomy of 25 fatal cases, reporting on these without any knowledge of the results of the investigations by Drs. Strong and Musgrave. The ameba coli was found in the stools of only three of these cases. Craig, however, isolated a bacillus identical with that found by Flexner in Manila, previously described by Shiga. The bacillus was practically identical with the bacillus typhosus. It agglutinated with the blood of the cases from which it was isolated and also with the blood of a few other cases of dysentery, but not of all, suggesting the possibility of the agglutinating power being lost, or that there were different varieties of dysentery in the hospital.

It would seem, therefore, that in Manila, we have two forms of dysentery, one an amebic form, in which the patient recovers or dies before reaching San Francisco, and the other due to a specific bacillus which if not promptly fatal persists for a long period in a subacute or chronic form.

QUACK DOCTORS, QUACK MEDICINE, AND A LAY JOURNAL.

Mr. Ewing Herbert publishes the *Brown County World*, at Hiawatha, Kansas, a paper that deserves commendatory mention in every respectable medical journal. Without going into any prior advertising of his course or making, so far as we know, any special religious pretenses, he publishes in a recent issue the following editorial announcement:

"We have at last done what we have wanted to do for many years—thrown out of this paper every advertisement that can be by any chance considered objectionable in any degree. And hereafter we shall print no offensive advertisements. . . . If persons are ailing they should not hesitate to consult a reputable physician. No medicine acts the same way on different persons. What benefits some harms others. From this time on we will not print advertisements of traveling quack doctors. We want clean advertising matter, or none. . . . Last year our patent medicine 'ads' amounted to $800. With one dash we have practically swept aside this source of income. We believe that the people who have glanced at Lydia Redham's offensive propositions, and at Slow's Specific, Bradshaw's Regulator, et al., including the bids of various quack doctors to cure weak and suffering men and women, will miss them in this paper with not a little pleasure. If you are ailing see a home physician, some good doctor you can confide in. It does not make any difference what ails you, do not be afraid to tell an honorable physician about it, and submit to his advice and treatment. Beware of quack doctors; they want your money and they will get it. And they can not cure you. If your home physician can not cure you, he will probably tell you of some eminent man in the medical profession who can help you; but he should warn you in a conscientious and disinterested way never to permit a quack doctor to treat you. Young folks should talk freely to their parents when ill. The parents will call a physician, if one is needed. Do not read filthy 'ads.' Do not buy quack medicines. Do not have anything to do with strange doctors. They are generally disreputable, and entirely unable to do any more for you than to mercilessly take your money."

[2] Johns Hopkins Hospital Bulletin, February, 1900.

This, a New York paper characterizes as a "step so radical that to read it will cause the hair of every normally constituted publisher to stand erect." We are glad that there are such abnormally constituted ones in the wild and wooly West and trust that time will develop more of them. When the newspaper leaders of public opinion, generally, denounce quackery we will have advanced a long step toward the millennium. At present they mutually defend themselves by each other's example and plead the rule that we should be suspicious of scruples that do not trouble other good men. A little more independence of conscience like that of Mr. Herbert would be a good thing if more generally distributed.

THERAPEUTIC PESSIMISM.

Whatever the scientific qualifications and aims of the practitioner of medicine, his especial function is the prevention and the cure of disease, the prolongation of life and the relief of suffering. He must be ever resourceful, and from the therapeutic point of view an optimist. In discussing the causes of therapeutic pessimism among the better men in the profession, Barker[1], in a recent address, points out that when therapeutics is spoken of, disproportionate consideration is given to pharmacotherapy. It is because they are insufficiently known and appreciated that dietotherapy, climatotherapy, hydrotherapy, kinesitherapy, electrotherapy, and psychotherapy are not ranked with pharmacotherapy, and yet in the majority of cases with which the physician has to deal, one or more of these is of far greater importance than treatment with drugs. Psychotherapy especially has a great future. Not until physicians become better psychologists and learn better how to apply psychic methods in the treatment of disease can the disappearance of such psychic epidemics as that represented by so-called christian science be hoped for. In the near future psychopathogenic mechanisms should be carefully studied in order that psychoprophylaxis can have a wider field.

BITS OF MEDICAL HISTORY OF PURITAN BOSTON.

A series of articles on "Doctors and Apothecaries of Puritan Boston," by A. Corbett, Jr., has been appearing in the *Boston Globe*. There are many interesting stories of their often varied experience, professional and otherwise, and of their queer ideas of disease and the remarkable remedial agencies employed. In the issue for August 15 is an account of the two Firmins. Giles Firmin was the first apothecary in Boston, "a godly man and an apothecary," is his epitaph. Firmin's son, also named Giles, was a chirurgeon and gave lectures on anatomy, illustrated by the use of a skeleton; he returned to England in 1645 and sought refuge, from starvation, in the ministry. Admitted to the ministry he settled in Stratford; after the restoration he was ejected from the ministry because he was a dissenter; he continued to preach, however, and to practice medicine gratuitously. He advocated the union of all churches. He died in 1697, 82 years old. The patent medicine trade got an early start in Boston. The means of advertising resorted to quite equal in their presumption those of to-day. In a souvenir booklet, "suitable to be given at funerals," entitled, "The Mourner's Cordial Against Excessive Sorrow," there occurs the statement that the publisher has a remedy on sale which "if taken, cureth grippings of the gutts and preventeth dry belly ach."

THE CHOICE OF A SITE FOR VACCINATION.

From the prophylactic point of view it is a matter of indifference on what part of the body vaccination is practiced. For the prevention of smallpox it is only necessary that the procedure be adopted early in life and be repeated at intervals—say seven years, unless special conditions seem to justify making the interval shorter. In order that the protection shall be most effective, the vaccinal lesion should be a positive and well-defined one. A scar that would be designated "good" from the professional point of view, may, however, be a source of disfigurement to personal beauty, and, as the world goes, it will not be wondered at that occasionally fond mothers will object to its presence in a conspicuous place. The arm is probably the most common site for vaccination, but in deference to the wishes of some mothers and out of regard for the sensibilities of esthetic young women, girls are not rarely vaccinated on the thigh. Other sites have also been proposed, such as the arm-pit, the popliteal space, etc., but none has proved universally acceptable. A French physician has recently suggested the sole of the foot as the best place for the purpose, on the ground that, with the individual in the erect posture, this is the only portion of the body that is not in the range of vision, and hence it can exhibit no unsightly scar. This may be thought a joke, but the suggestion is made in earnest. Other advantages claimed for this situation are the convenience of operation and of applying the dressings, the avoidance of complications and the possibility of bathing. The method is readily applicable in the case of children, while an adult could decide for himself or herself whether to submit to confinement in bed or the recumbent posture for the necessary period of time, or to select a more acceptable site.

---

[1] Johns Hopkins Hosp. Bulletin, July-August.

COMPARATIVE THERAPEUTIC VALUE OF DIGITALIS AND ITS DERIVATIVES.

There are probably few subjects in pharmacodynamics that have been more extensively investigated and more fully discussed than the physiologic action and the therapeutic application of digitalis and its derivatives, and there has been no want of contrariety of opinion with regard to some aspects of the matter. As the result of a research undertaken with the object of harmonizing some of these differences, Arnold and Wood[1] found that digitalin and digitoxin each represent the full circulatory power of digitalis. Digitalis, digitalin and digitoxin, stimulate the cardio-inhibitory mechanism, both centrally and peripherally. In larger doses they paralyze the intrinsic cardio-inhibitory apparatus. They all cause a rise of blood-pressure by stimulating the heart and constricting the blood-vessels. Excessive doses paralyze the heart-muscle in mammals, the organ stopping in diastole. Digitalin of German origin is a stable compound, 1 gram being equivalent to about 70 c.c. of tincture of digitalis. Digitoxin is not to be recommended for human medication on account of its irritant action, which makes it liable to upset the stomach when given by the mouth, or to cause abscesses when given hypodermically; and on account of its insolubility, which renders its absorption slow and its elimination irregular and causes a marked tendency to cumulative action. It is further pointed out that the failure to obtain clinically the good results that experimental observation would lead one to expect from the administration of digitalin may be due, as was formerly the case with digitalis, to the employment of too small a dose. That ordinarily prescribed is from 1/60 to 1/30 gr., while it has been shown that doses of ½ gr. can be administered safely and with advantage.

THE FEAR OF TUBERCULOSIS.

The antituberculosis agitation has its inconvenient features. It is impossible for a medical subject to be so generally discussed without exciting popular interest, and this is especially true in this case. A large portion of the public is already hysterical on the subject, and the California preacher who, though a prohibitionist, would rather have his home surrounded by dram-shops than to have a consumptive settle near him is a typical instance of the irrational terror that has been aroused. Even the efforts to aid the tuberculous are sometimes balked by this public craze. A physician, said to be a thoroughly competent specialist, was recently heavily fined in a Canadian city for attempting to start a sanitarium for consumptives; and at Limoges, France, a similar institution was ordered closed by the authorities after it had been mobbed and some of its inmates injured by missiles. This is what we may expect if the output of popular information of the quality now in vogue is kept up, as it has been during the past year or two. Every medical writer who has nothing better about which to write has his say on tuberculosis, seldom imparting anything new and often only reiterating the most extreme statements as to its mortality and contagiousness. Consumption is bad enough; it is probably the most deadly of our diseases, though there are one or two others that are close seconds, but it is made no better by creating an unreasonable fear of its deadliness. We can educate the people to avoid it without scaring them to death, or making them act like brutes to those that are its victims. It would be just as near the truth if we told them that it is an infection that few or none can avoid, but that this infection is comparatively harmless in at least the great majority of cases, and even in the minority the developed disease is not so hopeless as it was formerly thought to be. We can instruct the public that it is not viciously contagious, that its fatality largely depends on predisposition, and that there is far more danger from the promiscuous spitting in houses and conveyances than from contact with a consumptive, if reasonable and easy precautions are taken. While its mortality is apparently steadily, though slowly, decreasing with our better knowledge of the disease, it is only arousing a foolish hope to tell the public that it can be extirpated entirely—certainly not merely by quarantine or isolation.

ROUTINISM IN MEDICINE.

An English contemporary[1] takes occasion to criticise Dr. Osler's recent address at the opening of the Museums of the London Polyclinic. It objects to his inference that practitioners may be divided into routinists and rationalists, at least as far as Great Britain is concerned, and it evidently wants us to believe that there are no routinists in Great Britain. Noticing Professor Osler's related experience with a back-number country practitioner, it says: "We are happy to think that in this country no such person as the Pennsylvania routinist exists. . . . In this land we can assure the Professor he would seldom be able to go into the country without enjoying that pleasure which he proclaims so rare in America—the finding of a practitioner capable of diagnosing mitral stenosis, leucemia, myxedema and such diseases." The first part of this quotation appears to us like the judicious choice of a blissful ignorance, the second part is a misrepresentation; Dr. Osler never proclaimed any such thing and we would not believe he ever intended to infer such a libel. The diagnostic ability of the average regular physician in this country is not, from all we can learn, so far behind that of the representative average British physician—we certainly would not fear a fair test of the question. If we were to judge of the ignorance of the British practitioner by that of the editor of our contemporary on American matters, we should say it was very dense, as shown in his editorial referred to. He complains that the pictures drawn, "as far as his country is concerned, were overdrawn and not altogether kind," but he himself has shown altogether too little consideration for others in exercising his own imagination. Dr. Osler was right, and we believe his remarks will apply as well to Great Britain, France and Germany as to this country, and the picture he drew is as true to life in one way as that of the genial poet-physician whom our contemporary quotes is in another. It is the rationalist who knows how to dispense with superfluities and who is also the best practical man. Like "Dr. Benjamin," he too "flings off his scientific wrappers and goes at the work of curing stomach-ache and all the other mean unscientific complaints that make up the larger part of every doctor's business." But he does not fail with the larger problems and he may often see even farther into these minor ones of a physician's life to his patients' and his own advantage. It seems almost ridiculous to solemnly repeat such a self-evident truth, but its aspect to our contemporary as almost "claptrap," has tempted us.

---

[1] American Journal of the Medical Sciences, August, 1900, p. 165.

[1] The Physician and Surgeon, July 19.

Medical News.

The New Hospital of the Mexican Central Railroad at Aguas Calientes, Mexico, will soon be in operation.

The medical staff of the British army in South Africa consists of 466 army and 440 civilian surgeons, 566 female nurses and 5668 male nurses and orderlies, exclusive of local nurses and surgeons.

Dr. McCall Anderson, professor of clinical medicine in the University of Glasgow, has been appointed to the chair of systematic medicine made vacant by the resignation of Sir W. Gairdner.

Major-Surgeon John Van R. Hoff, of the Army, passed through Chicago August 21, on his way from Porto Rico to China, where he is ordered as medical director of the United States expeditionary forces under General Chaffee.

Dr. Tarnier's monument, a high relief in marble nine feet tall, will be placed in the wall of the hospital at Paris, where the famous surgeon held his clinics. The artist has represented him as operating on a patient, assisted by three students.

The Marquis of Bute has offered the University of St. Andrews, Scotland, the sum of £20,000 to be held as a fund for endowing a chair of anatomy in that institution. The subject will come before the University Court at a special meeting called for September 1.

Registration at International Medical Congress.—Up to August 5, 6170 members had registered at the Congress in Paris. Of these 2293 were from France; 805 from Russia; 572 from Germany; 412 from the United States; 324 from Italy; 222 from Great Britain; 219 from Spain; 147 from Belgium; 141 from Austria; 108 from the Argentine Republic and 101 from Switzerland.

Testimonial to Christian Fenger.—The Chicago Medical Society has appointed a committee, consisting of Drs. W. A. Evans, W. L. Baum, and J. B. Murphy, to arrange for a testimonial banquet to be tendered to Dr. Christian Fenger on his birthday, November 3. The affair will be national in character and is intended as a token of respect to Dr. Fenger, to show that his colleagues appreciate the services he has rendered his profession and humanity.

Dinner in Honor of Lord Lister.—Lord Lister was honored in Paris by a dinner given by the "Scientia" Society, August 1, at the *Restaurant des Congrès* in the Exposition grounds. About 60 guests were present. Lucas-Championnière told of his journey to Glasgow to see Lister, and how after seeing and working with him, he returned as an apostle to Paris but was not listened to. Pinard spoke of the debt owed by accoucheurs and their patients to Lister. In his own simple and quiet way, Lord Lister responded, telling of his early struggles, which were without result until Pasteur showed the way, and disclaiming credit for the benefits of his work to humanity, which he said was due to the happy accident of his epoch.

Vital Statistics of Scotland.—The Registrar-General's report for 1899 shows that 130,656 births were registered, of which 8488 were illegitimate, a birth-rate of 30.5 per thousand. The number of deaths registered was 79,548; 39,919 males and 39,629 females, a mortality-rate of 18.6 per thousand. The eight principal towns of Scotland had a birth-rate of 31.3 per thousand and a death-rate of 20.4 per thousand. Greenock had the highest birth- and the highest death-rate. Zymotic diseases caused 14.57 per cent. of the total mortality; influenza, 1.13 per cent.; measles, 2.92 per cent.; whooping-cough, 2.51 per cent.; fevers, 1.07 per cent.; diphtheria, 0.81 per cent.; cancer, 4.40 per cent.; phthisis, 9.43 per cent.; nervous diseases, 11.33 per cent.; circulatory diseases, 8.47 per cent.; respiratory diseases, 19.49 per cent.; digestive diseases, 7.41 per cent; violence, 4.07 per cent.

ALABAMA.

Dr. Robert E. Noble, Anniston, has been appointed acting assistant-surgeon in the army and is now on his way to China.

Dr. T. C. Thorington, city physician of Montgomery, gives the annual mortality of that city at 12.93 per 1000, for the year ending May 31, 1900. He states that it is the best record of any city in the Southern States.

CALIFORNIA.

Riverside County is erecting a hospital on a commanding site near the village of Arlington.

The Redding board of health met for organization August 8, and elected Dr. B. E. Stevenson president.

Bubonic Plague Reports have been decided by Superior Judge Hart, San Francisco, to be public property. The *Bee* of that city instituted mandamus proceedings to compel Secretary Mathews of the State Board of Health to produce the reports on bubonic plague given by Drs. Mouser and Ryfkogel. Dr. Mathews made answer that the reports were not public property, that the discretion for giving or not giving them out lay with the board of health, and furthermore that they were in the custody of the governor of the State.

DISTRICT OF COLUMBIA.

Dr. Larkin W. Glazebrook, Washington, has been reappointed deputy coroner of the District.

The Commissioners of the District, on August 9, appointed Dr. J. Ramsay Nevitt, Washington, coroner of the District, to succeed Dr. William P. Carr, term expired.

FLORIDA.

Key West presents a good showing from the health standpoint. Dr. John V. R. Plummer, city health officer, reports 28 deaths for July, the lowest mortality ever noted for that month. The lowest mortality in previous years was 40, in 1899. A peculiar feature in the report is that 4 deaths, or more than 14 per cent., are said to have been due to tetanus neonatorum, and 1 death to tetanus (adult).

ILLINOIS.

Dr. Robert Williams, of Carthage, will locate in Alden, Minn.

Dr. C. A. Fowler, Galena, has purchased the practice of Dr. Lucas, of Malta, and will locate there.

Dr. E. Sargent, who has been resident-physician at Mercy Hospital, Chicago, has opened an office in the Chase building, Moline.

St. Mary's Hospital, Quincy, is being enlarged by the erection of a new wing. When this is completed the hospital will accommodate 200 patients.

Dr. George N. Lucas, who has been practicing in Malta for five years has sold his property and will move to Elgin.

A hospital is to be established at Pekin, provided the necessary funds can be raised. Subscriptions to the amount of $9,000 have already been secured.

The report of the Harvard Cottage Hospital shows that during the year ended August 1, 115 cases, all surgical, were treated, with only one death. Dr. Colonel M. Johnson. Harvard, is surgeon.

Dr. Henry Hatch, Quincy, has agreed to establish a hospital of 35 beds and to cost $30,000, at Hannibal, Mo., provided that city will donate $15,000, a lot for the hospital, and free gas and water for five years.

The club system, with which we have fortunately been little afflicted in the United States, has invaded this state. An association has been incorporated recently in Bloomington, which for a "small consideration paid each month," agrees to pay the physicians' and druggists' bills of its membership. The explicit statement is made that any physician or druggist desired by the member can be employed.

Chicago.

Dr. E. H. Ochsner returned from Paris August 19.

Dr. Leo Loeb went this week to Woods Holl, Mass., for a few weeks.

Dr. E. Russell Ogden has returned. He spent his vacation in New London, Conn., and at other New England points.

Dr. Gustavus M. Blech and Miss Rose Bergenstadt were married August 9, at Wicker Park Hall, by Rabbi Bauer.

Drs. Homer O. Bates and Laura C. Bates are at their summer home, Thousand Island Park, N. Y., for the month of August.

Dr. John B. Murphy has returned from Paris bringing the first personal information about the International Medical Congress. He says that the attendance was fair, but that the foreign representation was not so large as had been expected. Germany, England and the United States had meager delegations. The work of the Congress was up to the average. The plans for official entertaining were crippled by the death of the King of Italy.

The Medical Arrangements for the thirty-fourth national encampment of the Grand Army of the Republic, are in the hands of Dr. T. Jay Robeson, late Major-Surgeon First Illinois Cavalry, U. S. V.; Dr. Arthur R. Reynolds, Health Commissioner, and J. F. Hultgen, who acts as secretary. They will be assisted by about 150 physicians, who will be assigned to meet all trains containing soldiers; they will visit quarters free morning and evening and will be designated by a badge and a G. A. R. hat. A temporary hospital has been arranged for at Medical Department Headquarters in the Keith building, Wabash avenue and Monroe street. Field hospitals provided with ambulances will also be established at various points along the line of march to care for emergency cases.

HEALTH DEPARTMENT.

According to precedent the mortality of the week following the heated term should have been as high as, if not higher than, that of the hot week itself. Precedents, however, have been set at naught, this year in many ways, and the recorded deaths last week are 27 per cent. fewer than for the week of continuous highest temperature on record in thirty years. Based on the Department's estimated population of 1,750,000, the death-rate for the week is only 13.5 per thousand, an unprecedentedly low figure for midsummer and marvelously low considering the high temperature immediately preceding. The most gratifying features are the decrease in the deaths of infants and children under 5 years of age, 192 last week and 275 the week before, and the decrease in deaths from the impure-water diseases, 121 last week, 191 the week previous. Of the 12 deaths from sunstroke, 9 occurred during the previous week, the reports from the coroner's office and from hospitals having been delayed. The department records show a total of 26 deaths due to sunstroke as the direct cause, besides many from chronic diseases hastened to a fatal termination by heat exhaustion. While all deaths are, of necessity reported to the Health Department, it is estimated that only about 70 per cent. of the births are so reported. Notwithstanding this discrepancy, the reported births last week outnumbered the deaths by one-third, 454 deaths and 605 births. The deaths reported for the week ended August 18, were 454, 38 less than in the corresponding week of 1899; the death-rate per thousand was 13.51 as compared with 14.75 in 1899. Males to the number of 259 died and 195 females. Of children under 1 year of age 130 died; between 1 and 5 years, 62, and over 60 years, 99. The principal causes of death were: Acute intestinal diseases, 116; consumption, 45; heart diseases, 31; nervous diseases, 27; violence, 19; Bright's disease, 16; cancer, 14; sunstroke, 12; convulsions, 10; apoplexy, 9; suicide, 5. The number of contagious diseases reported during the week was 49, of which 23 were scarlet fever and 26 diphtheria. Antitoxin was employed in 126 cases. At the stockyards, 31,715 pounds of meat were condemned. In the laboratory, 451 samples of milk and cream were analyzed, 7.53 per cent. of which were found to be below grade.

INDIANA.

Dr. A. B. Darby, of Waterloo, has received the Republican nomination as state senator for his district.

A physician of Monticello was fined $10 in a justice court for failing to put a "whooping cough" card on a house in which several children were suffering with the disease.

The Indiana State Medical Board has under consideration a uniform code of medical laws for the United States. Until this shall be accomplished, the board will adhere rigidly to the rule requiring all applicants from other states to pass the examination required before they are granted licenses to practice.

A committee from the Delaware County Medical Society, met the county commissioners and requested an appropriation of $10,000 for the establishment of a county hospital, of which there is urgent need. They agreed that if this appropriation was made, $10,000 additional would be provided from other sources. The commissioners temporized and pleaded poverty.

IOWA.

Some miscreant has twice in one week set fire to the office of Dr. Edward H. Knittle, Onslow.

Dr. G. L. Everall, of Farmersburg has sold his property and practice to Dr. Irving Munger, who moves to that place from Elkader.

KENTUCKY.

Dr. J. A. Averdick, Covington, returned from a three-months tour of Europe, August 11.

Two Kentucky physicians, Francis Wells, Louisville, and David Hampton, Covington, have started for the seat of war. They have recently been appointed acting assistant-surgeons in the army.

Dr. T. Hunt Stucky, Louisville, has been chosen medical director for the Triennial Conclave of Knights Templar. Upon him will devolve the organization of first-aid and hospital service during the conclave.

LOUISIANA.

The quarantine against Tampa, Fla., was raised August 18, by the State Board of Health.

Dr. Henry E. Menage, New Orleans, returned, August 8, from his service with the Army in Manila.

The "Senses Hospital," or Eye, Ear, Nose and Throat Hospital of New Orleans, realized $6,632.66 August 17, as the proceeds of a festival held for its benefit.

MAINE.

Dr. W. A. Purington, of Sangerville, was recently married to Miss Susie Weeks, of Chicago.

Dr. S. Watson Bragg was married to Miss Adele L. Leland of Enfield, August 14. Dr. Bragg is a practitioner of Montague and his wife received training as a nurse at the Eastern Maine General Hospital. They will reside in Montague.

MARYLAND.

The death-rate in Baltimore for the week ending Aug. 18 was 25.08, viz., whites 23.81 per cent., colored 32.66. These proportions show the greater effect of high temperature on the white race, the usual proportion being between the two races about 1 to 2½. The total number of deaths was 261, as compared with 174 for the corresponding week of last year; 85

were in children under 5, and 43 are attributed to "sunstroke." Cholera infantum caused 38, dysentery and diarrhéa 13, typhoid fever 9, and consumption 20.

The law requires persons removing night soil in Baltimore to secure a permit from the city commissioner of health and haul it through the streets to the city scows, where a fee is paid for dumping it. Instead of doing this, many persons employed in this work have been selling it to farmers living around the city. The practice has become so general, as to threaten to pollute the streams supplying a part of the city. The law is now openly violated. The State Board of Health, the city commissioner of health and the county officials are working together for the correction of the evil. It is thought that if the fee for dumping were abolished, there would be more ready compliance with the law.

MICHIGAN.

Dr. A. N. Treadgold, of Kilmanagh, is going to locate in Cass City.

Dr. J. C. Rutledge, Detroit, has been appointed acting assistant-surgeon in the army and expects to be ordered to the Orient.

Dr. J. Irving Mabee, of Rockwood, has joined the army medical department as acting assistant-surgeon, and started for the seat of war in the far east, August 15.

Dr. Louis W. Pease, Saginaw, has been ordered to report for duty at San Francisco as acting assistant-surgeon, U. S. Army. He served throughout the Spanish-American war as surgeon in the Thirty-third Michigan Infantry, U. S. V.

MINNESOTA.

The annual meeting of the board of trustees of the state asylum for the insane was held at Fergus Falls, August 9. Dr. David N. Jones, Gaylord, was re-elected president of the board.

"Electrical Institutes" in Minnesota are soon to have their rights tested by the State Board of Medical Examiners, which claims that no one has a right to administer electrical treatment for disease without first possessing a physician's license. The question hinges on whether or not electrical treatment constitutes practice of medicine under the statute.

MISSOURI.

The Macon County (Mo.) Medical Society will hold a clinical meeting at Macon, September 4.

Dr. Thomas J. Thorpe, St. Louis, was accidentally, and probably fatally shot on August 11.

Dr. Harry Tatum, a recent graduate of Jefferson Medical College, Philadelphia, has located in Brunswick.

Dr. Henry J. Schenck, of St. Louis, is to be married, August 30, to Miss Natalie Altheimer, of the same city.

Dr. Charles Gowans, St. Louis, was married to Miss Hermione Hinton, August 15. They will reside at 6013 Cates avenue.

The Bill authorizing the erection of a new city hospital on the site of that destroyed by the tornado was passed by the St. Louis city council, August 7.

Dr. Heber Robarts, of St. Louis, editor of the *X-Ray Journal*, is at the head of a syndicate which proposes to build a sanitarium devoted to the treatment of disease by electricity.

Dr. Edward Wallace Lee, who has just returned from Europe, will locate in St. Louis and devote himself exclusively to surgery. Dr. Lee was for some years professor of surgery in the Creighton Medical College, Omaha.

Kansas City quacks are to be vigorously attacked by the State Board of Health. If the local member of the board, Dr. S. C. James can make good his assertions and is backed up by law, great results should ensue, but most medical practice acts are noteworthy for the way in which they can be ignored and that with impunity and immunity.

MONTANA.

The epidemic of smallpox at Anaconda has cost Deer Lodge County nearly $20,000, since October last.

NEBRASKA.

Dr. L. A. Lansing, of Buffalo, N. Y., has located in Emerson.

Dr. P. T. Conlan, who has been practicing in Columbus, has located at Platte Center.

NEW JERSEY.

Dr. Peter B. Davenport has been appointed health officer of Vailsburg.

An automobile accident, which caused the death of a woman, is the reason for a $25,000 damage suit brought against Dr. W. L. Vroom, of Ridgewood, coroner of Bergen county. An endeavor is also being made to indict him for criminal negligence.

The management of the Children's Seashore House in Atlantic City is making an urgent effort to raise the sum of $4,000, which is required to keep this house open for its customary season. The establishment was erected in 1872 and has accommodations for 225 children. Up to the time the Children's Seashore House had closed last summer it had since its foundation treated 16,947 children, and 4088 mothers, or a total of 21,035 patients.

NEW YORK.

Dr. A. M. Leonard, Cicero, was married to Miss E. Vickery, of Clay, August 8.

The will of the late Dr. J. C. Rappold, Brooklyn, was filed for probate, August 9. His estate is valued at $12,000.

The Geneva City Hospital, Ontario county, N. Y., will receive $10,000 by the will of the late Judge Francis O. Mason, and an additional $80,000 on the death of his two sisters.

OHIO.

Dr. E. Homer Gee, of Xenia, a graduate of Rush Medical College, and late interne at the Freedmen's Hospital, Washington, has located in Zanesville.

Dr. Henry Verdier, Cincinnati, has started for San Francisco. He has been assigned to duty as acting assistant-surgeon in the army.

Smallpox appeared in 103 places in 53 different counties of the state between January 1 and August 1, according to the state health board's report. The total number of cases was 1647 and the deaths numbered 20.

The staff for the Protestant Hospital for the ensuing year was announced by the trustees, August 14. Dr. David N. Kinsman was appointed chief of staff; Drs. Charles W. McGavran and Clarence F. Schlitz, resident physicians, and George M. Waters, radiographer.

PENNSYLVANIA.

Dr. S. G. Burkholder, has removed from Chicago and will locate in Rothsville.

The little town of Catawissa is suffering from a mild epidemic of typhoid fever. During the week two new cases have occurred.

Anthrax has broken out among a large herd of cattle at Tunkhannock. Five have died, while 150 have already been exposed to the infection.

Seven cases of smallpox have developed at Erie, and a number of persons have been exposed to the disease. A rigid quarantine is being maintained.

The causes of death, reported by census enumerators to the clerk of the Orphan's Court in Buck's County, include "hart parlias," "paraliya," "hart truble," "newmonia" and "live cuplat," the latter being interpreted to mean liver complaint.

Thirteen employes of the Pennsylvania Railroad at Altoona were, August 17, taken seriously ill with nausea and cramps, supposed to have been due to polluted drinking water.

In Allegheny Furnace, a suburb of Altoona, a very large number of persons are suffering with diphtheria. Five new cases were reported on August 17.

Vineland and Millville, two adjoining towns, are waging war against each other over the proposed establishment of a system of sewage by the former [illegible] It [illegible]eved that should it drain into Maurice Ri[illegible] of Millville will become infected. C[illegible] attended matters for both places, but he is now in Paris. Millville threatens to get an injunction in regard to the matter.

Dr. L. B. Olinger, Pittsburg, has been made an acting assistant-surgeon in the army, and has been ordered to leave for the Pacific coast, there to report to the surgeon-in-charge for assignment to duty in China.

Philadelphia.

Dr. W. W. Keen will return from Europe about the end of September.

Dr. Wharton Sinkler sailed for Europe, August 18, to be gone several weeks.

Dr. H. W. Cattell has resigned from his position as pathologist to the Philadelphia Hospital.

Through the bequest of George W. Cross, of Lower Merion, the Wills Eye Hospital has become beneficiary to a considerable estate.

Different manufacturers of quinin of Philadelphia are now busy endeavoring to supply large orders for that drug to be sent to the army in China.

The physician to the Empress of China is Dr. Hu King Eng, who graduated from the Woman's Medical College in this city several years ago, and is now in Pekin.

The Board of Health has recently purchased two new ambulances for the Philadelphia Hospital, and also four disinfecting wagons, which will soon be completed for service.

One of the daily papers—*Bulletin*—of this city has for some time been exposing another fraud in the shape of a "Doctor of Suggestive Therapeutics," who has been duping the unwary.

The Dairy and Food Commissioners have now on file twenty-three bills against persons selling adulterated articles of food. Most of these are for selling oleomargarin under the guise of butter.

Dr. George S. Mintzer, resident-surgeon at the Medico-Chirurgical Hospital, has been appointed surgeon in the United States Army. He has been ordered to report for duty at San Francisco and left, August 18.

A mild epidemic of typhoid fever has broken out in the northwestern section of the city, which has been attributed to drinking impure water. Many of the cases have been admitted to the German and St. Joseph's Hospitals.

The Children's Country Week Association during the past week despatched 350 more children to the surrounding country districts. Within the past three weeks this association has sent 4000 children to spend a few days at country homes.

The roof garden on the top of the Children's Hospital at Twenty-second and Walnut streets has proved of the greatest utility in keeping down the mortality of the hospital during the extreme hot spell which has been prevailing here for several weeks.

Saturday, August 11, was the hottest day that has ever been recorded for this month in Philadelphia. The maximum temperature was 100.06. The next day, Sunday, was the fourth hottest day ever recorded, and registered 99.2 at 3:50 p. m. These figures, it must be remembered, were those obtained on the fourth floor of the postoffice building. On the ground the heat was almost intolerable. On August 12, ten deaths were attributed to the heat.

A material increase in the mortality is noted for this week, the total number of deaths being 550, an increase of 98 over that of the previous week and an increase of 169 over the corresponding period of last year. The principal causes of death were: sunstroke, 56; apoplexy, 16; nephritis, 26; cholera infantum, 42; tuberculosis, 54; marasmus, 27; inflammation of stomach and intestines, 24; diphtheria, 64 cases, 10 deaths; scarlet fever, 22 cases, 1 death; typhoid fever, 77 cases, 8 deaths.

RHODE ISLAND.

An emergency hospital is to be established in Pawtucket under the charge of Dr. Francis M. Harrington. An option has been secured on a suitable house at 374 Main street and the promoters intend to have the hospital ready for use by September 1.

SOUTH DAKOTA.

Charges have been preferred by H. Kautzman, editor of the *Yankton Beacon Light*, against Dr. Ross, the superintendent of the state asylum for the insane at Yankton. The charges include official misconduct, selling of state property and drunkenness. It is believed that the fight is purely political, as the management of the asylum has been satisfactory.

TENNESSEE.

Dr. H. F. Ham has been selected by the county board of health to take charge of the Emergency Hospital, Memphis, vice Dr. McKay, suspended.

Erlanger Hospital, Chattanooga, is soon to have a modern operating-room. Dr. Henry Berlin has secured donations to the amount of about $1000 for this purpose, and the work will be undertaken at once.

Dr. Alexander B. Dancy, who has been taking a post-graduate course in New York, has returned to Jackson. He has had inflammatory rheumatism for two months and is unable to resume practice at present.

Dr. Benjamin B. Cates has been elected to fill the chair of surgery in the Tennessee Medical College, Knoxville. Dr. H. J. Kelso takes the chair of anatomy; Dr. S. R. Miller takes Dr. Kelso's old place as professor of clinical and operative surgery, while Dr. C. R. Zemph becomes professor of materia medica and therapeutics. The chair of obstetrics was united with that of gynecology under Dr. S. M. Miller. Those changes were necessitated by the recent death of Dr. John L. Howell.

TEXAS.

The cost of fighting smallpox in Galveston, from February till May was $2748.74. In his report to the Board of Health Dr. C. H. Wilkinson, health physician, states that 30 cases of smallpox were cared for in the camp, and 13 suspects were held in detention. The health department made 1410 out of the 2427 vaccinations reported, inspected 2053 premises, removed 10,184 dray loads of garbage and 1026 dead animals.

VIRGINIA.

Dr. Warren Jacobson, Richmond, has been appointed acting assistant-surgeon in the army and has been assigned to duty in China.

Eighty-nine candidates were successful in passing the recent examination before the state medical examining board at Lynchburg.

WASHINGTON.

Dr. W. C. Cox, Everett, has been appointed by Governor Rogers a member of the State Board of Medical Examiners, to succeed Dr. Van Zandt, of New Whatcom.

The citizens of Spokane living near the proposed site of the Sisters of Providence Hospital are making the usual protest against the location of the hospital and threaten to bring injunction proceedings.

WEST VIRGINIA.

Forty new cases of smallpox were reported from the interior of Taylor County, and a general quarantine has been established.

WISCONSIN.

Dr. G. I. Hogue, who has been interne at the Milwaukee Hospital, has been appointed acting assistant-surgeon in the army, and will leave for San Francisco in a few days.

CANADA.

Dr. Harry J. Watson, Ottawa—Trinity, 1896—has been appointed a surgeon in the United States Army for service in China.

Dr. James Third, superintendent of the General Hospital, Kingston, Ont., has resigned that position. It is understood that Dr. Herald, of the same city, is likely to be appointed his successor.

Dr. A. D. Stewart, late of the house staff of the Toronto

General Hospital, has been appointed surgeon of the C. P. R.'s palace steamer Empress of Japan, plying between Vancouver and Yokohoma. He took charge August 20.

DR. GORDON BELL, secretary of the Board of Health of Manitoba, is investigating outbreaks of typhoid fever in Winnipeg and other places throughout that province. On the completion of his inspection, a pamphlet will be issued on the subject.

THE BOARD OF HEALTH of Woodstock, Ont., has decided to compel bakers to give up the present bread system of giving small tickets to their customers, as they consider the distribution of these around to different houses is liable to spread disease.

DR. J. N. E. BROWN, Dawson City, for several years secretary of the Ontario Medical Association, who went to the Yukon two years ago as secretary to Governor Ogilvie, has been promoted to the position of secretary of the Yukon Territory.

DR. A. C. SINCLAIR, Rossland, B. C., local Dominion Health Inspector, reports that there have been no fresh cases of smallpox in Rossland or Nelson since he assumed charge of the maintenance of quarantine, May 1.

THE NURSES who were sent by the Victorian Order of Nurses to Dawson City two years ago, and who did such heroic work, have been withdrawn, because the improvement in the conditions of life has rendered their further presence unnecessary.

THE CHIEF of the Dominion Health Department, Dr. Montizambert, Ottawa, is on his way to Dawson City to investigate smallpox there and to take action to prevent the spread of the disease. He will also determine whether it is expedient to raise the quarantine.

THE CANADIAN RED CROSS COMMISSIONER TO SOUTH AFRICA.

Dr. George Stirling Ryerson, founder of the Canadian Red Cross Association, has returned to his home in Toronto, and in an interview accorded the daily press gives some very interesting opinions regarding hospital work in that country during the progress of the war. One of the interesting statements made by him is to the effect that Lady Roberts' hospital for sick and wounded soldiers at Bloemfontein is almost entirely fitted out with supplies furnished by Westmount—a suburb of Montreal—contributors. He considers the insinuations of Mr. Treves in regard to "the plague of women" as ungracious and uncalled for, as he is loud in his admiration for the good work performed by Lady Roberts, her daughters, and other English ladies of wealth and station. Shortly after Dr. Ryerson's arrival in South Africa, where he went as Canadian Commissioner of the Red Cross Association, he was appointed British Commissioner at Lord Roberts' headquarters. Here he had abundance of opportunity of observing in every direction. At Bloemfontein there were sometimes five thousand sick at one time; fifty-three deaths occurred there in one day, and altogether there occurred there 1900 deaths in six weeks. Being interrogated as to what foundation existed for Mr. Burdett-Coutts' charges, he declared that these accusations were substantially incorrect. He had never made any complaint to Dr. Ryerson while in South Africa, although he knew that the Canadian Commissioner had a large amount of money and stores at his disposal. When one considers the difficulties that had to be surmounted, Dr. Ryerson states that the hospital arrangements could not have been more admirable. Rudyard Kipling he also scores. As a Canadian he is very proud of the laurels won by his countrymen in South Africa.

STATE OF HEALTH IN THE YUKON DISTRICT.

The report of the Medical Health Officer of the Dawson district, dated June 23, refers to the state of health in the Yukon at that time. Dr. J. W. Good states there is no typhoid, no diphtheria, no smallpox—five cases since reported—and no dysentery. This condition of affairs is very gratifying and is said to be due largely to the fact that Dawson has now a good supply of drinking water. At the date mentioned, the number of pay patients in the Good Samaritan Hospital was 11; number of non-paying, 12; total, 23. The number of pay patients in St. Mary's Hospital was 4; non-paying patients, 14; total, 18. The system of having all non-paying patients make declaration as to the state of their finances, certified to by a friend, before their admittance into either of the hospitals is said to work with great smoothness. During the time the smallpox was prevalent in different portions of the United States and Canada, the medical health officer urged the board of health to be prepared for an outbreak of the disease by laying in a quantity of vaccin, as vaccination had not as yet been performed to any extent in that district. The vendors of diseased meats, rotten eggs, and unsuitable foods of all kinds have been watched very closely during the past year, and prosecutions along these lines have resulted in much good in this direction. It is stated that the water supplied by the new company is of a good quality, and the source of the water-supply is believed to be good. Improvements have been made in the way of drainage, and obstructions of various kinds have been removed from the streets. The question has arisen as to what shall be done with a few patients in the hospitals at municipal expense who will never recover their health and strength in Dawson. The health officer advises, to save these from becoming a chronic burden on the community, that they be especially examined, and then all of them shipped out simultaneously in charge of an intelligent nurse. From an economical standpoint this would pay Dawson City.

THE ONTARIO MEDICAL LIBRARY ASSOCIATION.

The thirteenth annual meeting of this association was held in the library rooms on June 28, the president, Dr. J. F. W. Ross, in the chair. The secretary, treasurer and curator read encouraging reports, showing that substantial progress was being made, and that the library was of very great value and usefulness. The president is of the opinion that next year the provincial government will apportion a grant for the benefit of the association. The by-laws and catalogues of the association are now in the printer's hands, and in the course of a short time will be sent out to members of the profession in Ontario. Dr. N. A. Powell, as curator, reported that 161 new volumes and three cases still unopened had been added to the library during the past year. Dr. Powell is a member of the American Association of Librarians and is enabled to secure duplicates from other libraries in exchange. At a meeting of the board of directors, held on July 4, Dr. Ross was re-elected president; Dr. R. A. Reeve, first vice-president; Dr. A. A. Macdonald, second vice-president; Dr. G. H. Carveth, third vice-president; Dr. H. J. Hamilton, secretary; Dr. H. A. Bruce, treasurer; Dr. N. A. Powell, curator, and Dr. W. J. Wilson, assistant curator.

ASSOCIATION OF EXECUTIVE HEALTH OFFICERS.

The fifteenth annual meeting of this association met in Kingston, Ont., on August 14 and 15. In the absence of the president at the opening of the session, Dr. T. V. Hutchinson, London, Dr. William Oldright, Toronto, took the chair. Mayor Minnes delivered an address of welcome. Mr. A. McGill, B.A., assistant analyst of the Department of Inland Revenue, Ottawa, read the first paper. The subject was the "Effects of Food Preservatives on Public Health," and the essayist took the stand that the use of chemicals to destroy the germs in milk was dangerous to human life. Dr. Sheard, Toronto, stated that he had had several cases come under his notice where persons, especially young children, were poisoned by the re-freezing of ice-cream. Dr. Bryce thought that the importance of cleanliness in the dairy had not made the advances it should have in the last twenty-five years. Dr. Sheard read a paper on his experience in recent vaccination work. In the evening the delegates enjoyed a moonlight excursion among the Thousand Islands, given in their honor. On the meeting assembling on the second day, Dr. Cassidy, of Toronto, read an interesting paper on tuberculosis and means for its cure. The president, Dr. Hutchinson, of London, delivered the annual address. It dwelt with the sanitary progress of the century. The education problem was the subject of a well-prepared paper by Dr. Bryce, as viewed from a public health standpoint. Dr. E. E. Kitchen, St. George, delivered an address on "The Sanitary Needs of Cheese Factories and Creameries." Dr. Herald gave a brief outline of the sewer system of Kingston. Dr. Bryce read a paper by Mr. Willis Chipman, C.E., Toronto, on "Septic Tank Method of Sewage Precipitation." Dr. W. [illegible] patho[illegible] Queen's University, contributed a paper on "Vitality of Typhoid and Diphtheria Bacilli in Milk." A paper on the use of antitoxin in the Toronto Contagious Disease Hospital, prepared by Professor Shuttleworth, was read by the secretary. A motion to establish laboratories at London and Kingston was carried unanimously. Dr. W. T. Connell was elected president, and Brantford was chosen as the next place of meeting.

LONDON LETTER.

The British Medical Association.

(Continued.)

PROBLEMS IN RURAL SANITATION.

Dr. John C. Thresh, president of the Section of State Medicine, in his introductory remarks, said that one of the most interesting problems which has engaged the attention of scientists during recent years is that of the period for which man will continue to live on this earth. The effect of over-population is well exemplified in the periodic famines generally associated with pestilence, which affect wide areas and millions of people in India and China, countries in which the population has attained its maximum density.

The purely rural population is slowly decreasing and the urban population rapidly increasing; therefore, year by year the feeding problem becomes more serious. Land is going out of cultivation and decreasing in value, yet it is often impossible to obtain a small quantity to effect sanitary improvements. In most of our towns every house is efficiently drained and abundantly supplied with pure water, in the rural districts, nuisances from the improper disposal of filth abound on every side, and the water-supplies too often are unsatisfactory in both quantity and quality.

One of the greatest problems of the age is how to bring back the people to the land. One of the chief requirements for restoring prosperity to our rural districts is increased facilities for acquiring small areas of land for sanitary improvement. With a sufficiency of land adjoining or near each house, the necessity for sewers would be avoided in most of our rural districts. The supply of water to our cottages is another important problem. Sanitary authorities are averse not only to the expenditure necessary to provide a public supply of water, but also to causing landlords to provide such a supply.

A vitally important requirement is decent cottages for our rural laborers. Many acts of parliament have been passed, having for their object the better housing of the working classes. Those who drafted these acts worked on the erroneous assumption that unless carefully restrained, sanitary authorities would be infected with a mania for building. Consequently, the utility of these laws has been practically nullified in the rural districts. What is needed is an act which will encourage sanitary authorities to build and will offer them every possible facility to provide decent accommodation for the laborer with the least possible trouble and at the lowest possible cost.

TREATMENT OF THE WOUNDED AT SEA.

Inspector-General Belgrave Ninnis, M. D., R. N., in the opening address of the Section of the Navy, Army and Ambulance, spoke of the means at the disposal of the naval medical officer for the treatment of the injured on board a man-of-war, more especially during an action.

The essentials of a fighting ship comprise the maximum of offensive and defensive armament combined with capability of rapid motion and a steady platform. Light and fresh air are especially necessary to the sick, but these can be obtained in sufficient quantity only above the water line where the sick and injured would be exposed to danger during an action. For these reasons the naval medical officer must not be judged by the ordinary standard, as he is obliged to work under great disadvantages. He must depend entirely on himself, and history has shown that zeal and resourcefulness are notable characteristics of the naval branch of the profession.

It is intended in the future to supplement fleets in war times with floating hospitals, having modern fittings and appliances. During action these ships would keep out of range, but would collect the wounded when the battle was over, and as they sailed under the regulations of the Geneva Convention would be free from molestation or capture.

ADDRESS IN OBSTETRICS.

The address in Obstetrics was delivered by Dr. W. J. Smyly, vice-president of the Royal College of Physicians in Ireland. He said that though some knowledge of midwifery had existed since the earliest times, scientific midwifery commenced with Ambrose Paré, in the sixteenth century. In the first half of the present century the mortality of childbed, especially in hospitals, was probably greater than in any other period of the world's history. Toward the close of the seventies, however, an improvement suddenly took place. In the Paris Maternity, for example, the mortality dropped in one year from 8 to 4 per cent. and in 1881 to 1 per cent., and has since improved. Semmelweis showed that the heavy puerperal mortality at the Vienna Hospital was due to infection from the fingers of students engaged in post-mortem examinations. But his discovery fell on deaf ears and he fretted himself into insanity. With a little more patience he might have discovered that the seed he had sown was slowly bearing fruit. Michaelis and Lange adopted his views with success. Simpson warmly advocated them in England. The wonderful discoveries of Pasteur, published two years before the death of Semmelweis, confirmed his views and placed them on a scientific basis. Lister completed the work by his discovery of antisepsis. But it was not until 1870 that antiseptic principles were applied to obstetrics and practically banished puerperal fever from the hospitals. At first the Listerian method was closely followed, but it was too cumbrous for general practice. The spray was replaced by the douche, and the uterus was washed out after every labor. This process reached its climax when permanent instillation was introduced by Schückling. Soon serious accidents and even deaths from injection of antiseptic fluids and air into the veins began to multiply. Döderlein then showed that douches acted injuriously by removing natural secretions, which had in themselves antiseptic properties. Consequently, at the Leipzig Hospital, prophylactic douching was abolished and the mortality fell 10 per cent. The fact taught by Semmelweis and Sir J. Simpson, that infection is carried chiefly by the hands, shows the importance of attending to this detail. "No handling, no septic infection," was not far from true. Leopold has proved that patients delivered without vaginal interference make a better convalescence than those who have been examined even with the most scrupulous antisepsis. Experience, therefore, proves—what bacteriological investigation leads us to expect—that aseptic hands can not be produced by any known process. Local interference should, therefore, be restricted within the narrowest possible bounds. The best method to insure this was to resort to diagnosis by external examination. Dr. Smyly's advocacy of this, which he considers the most important advance in modern midwifery, is the most valuable and practical point advanced in the whole meeting of the British Medical Association. In 1888 Credé wrote, "Even the simplest manipulation may cause infection . . . internal examination should be avoided altogether." By external examination the presentation and position of the fetus, whether the fetus be living, dying, or dead, and whether there are one or more children, whether labor has set in or not, and its course and progress, can all be ascertained. Pelvic deformity is suggested by pendulous abdomen and abnormal mobility and obliquity of the uterus, especially in primiparæ. It is an ominous sign to find the head above the brim after labor has commenced. In prolonged labors danger is indicated by thickening of the upper, and thinning of the lower, uterine segments, elevation of the contraction-ring and prominence of one or both round ligaments. External examination is equally useful in the third stage of labor, but not only is external examination safer than vaginal, but it is also more reliable. In the Rotunda Hospital, Dublin, where the students are obliged to write the results of their examinations, the speaker found that mistakes in diagnosis were much more frequent with vaginal than with external examinations. But there are two things which can be made out only by vaginal examination—the condition of the os and prolapse of the cord. If for any reason, such as inexperience or a very fat and rigid abdominal wall, external examination is unsatisfactory, the vaginal method becomes necessary.

PREVENTION OF INSANITY.

In the Section of Psychology, Dr. Percy Smith read a paper bearing this title. There were, in 1899, 105,086 lunatics in England, an increase of 3114 on the previous year, which was the largest increase recorded. There was also an increase in the ratio of the insane to the general population. Heredity was given as a cause in 20.4 per cent. of male, and in 25.9 per cent. of female patients, according to the figures of the Commissioners of Lunacy for 1893-1897. Next to heredity, alcohol was the most prominent cause, accounting for 22 per cent. of the male and 9.1 per cent. of the female cases. Simple drunkenness should render an individual liable to arrest, and it should be made penal to serve a habitual drunkard with liquor. As to general paralysis of the insane, the yearly average of cases was 13.1 per cent. of the male, and 2.8 per cent. of the female cases. The predominating influence of syphilis in its causation is now generally recognized. Syphilis should be made a notifiable disease—a course which would check its ravages and prevent general paralysis.

OCULAR HEADACHE.

Mr. W. A. Brailey (Guy's Hospital) read a paper on this subject. It is a general law that the greater the error of refraction, the less the effect on the head, because a great defect leads to abandonment of the effort of accommodation, the patient seeing as best he can without it. Uncorrected presbyopia is a rare cause of headache, except just at its commencement. It might cause strain and burning, but not headache. Similarly great inequality of refraction gives comparatively little trouble, the worse eye being unused.

GASTRIC ULCER.

Dr. J. F. Payne (St. Thomas' Hospital) read a paper on this subject. He said that the condition was becoming increasingly prevalent. Statistics of the six quinquennial periods, 1870-1899, showed that the number of cases of gastric and duodenal ulcer admitted to St. Thomas' Hospital were respectively 30, 38, 70, 103, 174, and 216. This was parallel to the increase of other digestive diseases, e. g., appendicitis. Only one diagnostic sign had been added in the last thirty years—hyperacidity of the gastric juice. The peculiar pain was present in only a minority of cases, and in some, pain was entirely absent. As to hematemesis, he was surprised to find that out of 48 fatal cases, it had occurred in only 14, while in non-fatal cases it had been present in 95 per cent. His explanation was that many cases proved fatal by perforation, in which complication hemorrhage was known to be uncommon, while non-fatal cases were often sent to hospitals for that very symptom. As to the hyperacidity, he knew little about it, for it was not justifiable to pass a tube into a stomach, possibly the seat of ulceration. The main principle of treatment was to give rest to the stomach by rectal feeding. It was doubtful whether the rectum absorbed much food. Peptonized food was the most likely to be absorbed. He allowed a little warm water by the mouth, but not for the first twenty-four hours after hemorrhage. A danger of long-continued rectal feeding was syncope. Rectal feeding might safely be continued for sixteen days if water was given by the mouth, and for seven days if water was withheld.

CEPHALOTRIPSY OF THE AFTER-COMING HEAD.

Mr. J. H. Targett (London) said that this operation was hardly referred to in the text-books. It was, of course, only rarely required. He had performed it in one case in which no doubt Cesarian section would have been the better operation, but this was declined. The patient was a rickety dwarf, aged 29 years, and was near the end of the ninth month. Labor was induced by hydrostatic bags, after which a leg was brought down. Delay took place and it was decided to extract. The trunk was delivered, but the head remained in a position of flexion above the contracted brim. As no impression could be made on it, and as the funis had ceased to pulsate, craniotomy was performed. The suboccipital region was chosen as the most accessible. On applying the cephalotribe, the lower blade was in apposition with the face, but the upper could not be passed over the occiput, owing to lateral contraction of the pelvis and incomplete dilatation of the lower segment of the uterus. The result was that the end of the blade repeatedly caught in the edge of the perforation. The blade was, therefore, passed into the skull through the perforation and the base crushed in its anteroposterior diameter. The plan succeeded admirably. The cephalotribe was, he thought, best applied in the manner followed in this case, because subsequent experiments gave the same result.

Correspondence.

State University and Higher Medical Education.

ST. PAUL, MINN., July 31, 1900.

To the Editor:—In your editorial of July 21 you specifically mention Michigan, Minnesota and Iowa, and allege that by low fees and mediocre requirements for entrance and for graduation, university medical schools acquire larger classes than they can properly instruct, that their clinical material is insufficient, and inferentially they are obstructive to the advance of medical education. Michigan and Iowa will doubtless resent this attack and defend themselves.

Minnesota's fees are $100 per annum. There are none higher to my knowledge, excepting a small number of schools in our largest cities. Our entrance requirements are equaled by few and *excelled by none excepting* Harvard and Johns Hopkins' Universities and possibly the College of Physicians and Surgeons, New York. Our entrance examination is now equivalent to that required for admission to the academic department of the University of Minnesota. In two years' time it will be equivalent to a sophomore, and in three years time to a junior entrance in the academic department, The twin cities of Minneapolis and St. Paul, with a population near 400,000 and numerous hospitals of modern type, afford unlimited facilities for clinical instruction, while our laboratories are not surpassed in America. PARKS RITCHIE,, M.D.
Dean, College of Medicine and Surgery, University Minnesota.

[Dr. Ritchie evidently did not read very carefully the editorial referred to. The reference to the three universities named was certainly complimentary rather than otherwise. The main point of the editorial is not touched on, viz., that the medical departments of state universities have not taken the lead in the movement for higher medical education. There was no intention to reflect on the medical departments of the Universities of Michigan, Iowa or Minnesota, as each of these is recognized as being in the front rank of medical educational institutions.—ED.]

Castor-Oil in Neuralgia.

ASHTON, R. I., Aug. 13, 1900.

To the Editor:—As touching the treatment of facial neuralgia by castor-oil, your correspondent, Dr. W. S. Caldwell, in his "Rambling Notes of a Roving Doctor," in THE JOURNAL of August 11, page 368, says the theory entertained in the Allgemienes Krankenhaus, Vienna, is that the beneficial effects of this mode of treatment result from the elimination of toxins, which, absorbed into the circulation, produce this disease.

About a month ago a young woman appealed piteously to me for relief from supraorbital neuralgia, from which she suffered excruciating agony. She had been treated with various remedies by her brother, who is a physician in good practice, without benefit. On the advice of a young hospital surgeon the brother intended to have the supraorbital nerve resected, but deferred the operation until after his return from Europe, where he had gone, and was expected back in three weeks.

I prescribed castor-oil to be taken two or three times a week, from which she obtained immediate relief, continuing to the present. She still takes the castor-oil at less frequent intervals. Strange to say the oil does not purge her, which would seem to indicate that the remedy, in this case at least, exerts a beneficial influence apart from its cathartic effect.

N. O'D. PARKS, M.D.

Not a Case of Death from Nitrous Oxid.

In the symposium on anesthetics presented before the New York County Medical Association last Spring—see THE

Journal, vol. xxxiv, pp. 705-712—reference was made to a fatal case from nitrous oxid, reported in Philadelphia. The case occurred in the practice of Dr. John D. Thomas, who sends the following letter to correct the erroneous impression that death was caused by the nitrous oxid.

New York City, Aug. 18, 1900.

To the Editor:—This was not a case of death under nitrous oxid. A personal friend of mine had taken the gas on three previous occasions, and there was no apparent indication that he should not take it again. The gas was given and the right upper second and third molars were extracted. His recovery was complete in the usual time, and he rinsed his mouth with a tumbler of water while sitting in the chair. I had gone to my desk in another part of the room, and he arose from the chair and walked to the washstand, ten feet away. He filled the glass and returned to the cuspidor beside the chair and continued rinsing the mouth while standing. He conversed with me in the meantime. This, he repeated until he had used three glasses of water, occupying at least twenty-five minutes, after which he stood before the mirror, and with his right hand drew back his lips and endeavored to see where the teeth had been taken from. As he removed his hand he looked at it and said: "That hand feels numb." He looked a little pale, and as my first thought was that looking at the wounds had made him feel faint, I directed him to lie down on the couch while I proceeded to get him some brandy, and then I realized that his speech was thick and indistinct. Physicians were immediately summoned, and everything was done to save him, but he died about four hours afterward. The coroner's jury gave a verdict of death from apoplexy, and that the gas was not the cause of it, in accordance with the medical testimony given there.

The gentleman was certainly in such a physical condition that any exciting cause might have produced the same effect, and his taking the gas was but an incident leading to that effect." Yours respectfully,

John D. Thomas, M.D.

Deaths and Obituaries.

William J. Musgrove, M.D., was found drowned in the river at Hudson, Wis., August 11. He was graduated from McGill University, Montreal, in 1882, had practiced for several years at Drayton, N. D., and since 1892 at Grafton, N. D. He was Vice-President of the State Board of Health, and of the State Medical Society. He had been out of health and despondent for some time, and it is supposed that he committed suicide.

David W. Conaughy, Latrobe, Pa., died August 10, after a long illness, from asthma complicated by the extreme heat, at the age of 72 years. He was a graduate of Jefferson Medical College, Philadelphia, of the class of 1858; a member of the American Medical Association, State Medical Association, etc. He was highly esteemed and was intimately associated with all plans for the growth and betterment of Latrobe.

William J. Elstun, M.D., formerly of Indianapolis, died at Washington, D. C., August 10, at the age of 62 years. He was a graduate of Bellevue Hospital Medical College in 1866, served as a physician at the Central Hospital for the Insane, Indianapolis, and was appointed special medical examiner in the pension department by President Harrison.

Henry S. Hurd, M.D., died August 11, at the home of his son, Dr. Henry M. Hurd, superintendent of Johns Hopkins University Hospital. Another son is Dr. Arthur W. Hurd, superintendent Buffalo State Hospital for Insane. The deceased was born in Roxbury, Conn., in 1815, and had practiced in Galesburg, Ill., from 1854 up to three years ago.

Elam L. Stewart, M. D., died at Carmi, Ill., August 11, aged 76 years. He was a graduate of Jefferson Medical College, Philadelphia, of the class of 1860; served during the Civil War as surgeon of the 87th Illinois Regiment, and was the first mayor of his native town, Carmi.

George W. Livesay, M.D., died at Ironton, Ohio, August 5, aged 75 years. He was born in West Virginia, took his academic course in the University of Virginia and Columbia College, N. Y., and was graduated in medicine from the University of Pennsylvania in 1848.

Edwin Evans, M.D., died at Rome, N. Y., August 16, aged 56 years. He was graduated from the College of Physicians and Surgeons, New York, in 1870, and was a member of the visiting board of the Oneida County Hospital.

Edgar A. Grafton, M.D., Montreal, P. Q., was drowned while bathing in the St. Lawrence river at Berthier, P. Q., July 29. He was 33 years of age and a graduate of McGill University, Montreal, of the class of 1891.

Fred W. Meyer, M.D., died recently at Aguas Calientes, Mexico, of typhoid fever. He was a graduate of the College of Physicians and Surgeons, Chicago, 1899. He was buried at his former home, Montezuma, Ia.

John L. Ancrum, M.D., Abbeville, S. C., died at Rossdhu, August 6. He was graduated from the Medical College of the State of South Carolina, Charleston, in 1860, and retired from practice a few years ago.

Charles W. Parsons, M.D., Louisville, Ky., dropped dead from heat exhaustion, August 18. He was a graduate of the medical department of Washington University, St. Louis, of the class of 1857.

Albert Paul Ruedi, M.D., Forest Hill, Cal., committed suicide by shooting himself through the heart, August 6. He was 56 years of age, and had had a hemorrhage from the lungs a few days before.

Thomas H. B. Brown, M.D., died suddenly at his home in Bridgewater, Va., August 13, at the age of 65 years. He was graduated from Jefferson Medical College, Philadelphia, in 1859.

John F. Kincheloe, M.D., Conway, Ark., died August 5, after a long illness. He was a graduate of the medical department of the University of Nashville, Tenn., of the class of 1871.

William B. Winston, M.D., of Memphis, Tenn., died August 12, from gastric cancer. He was a graduate of the medical department of the University of Nashville, 1861.

Theodore C. Laverty, M.D., of Middletown, Pa., died at that place on August 15. He was a graduate of the Jefferson Medical College, class of 1854.

Henry J. Costello, M.D., a resident of Philadelphia, died on August 13. He was a graduate of the Jefferson Medical College, 1895.

Julius C. Rappold, M.D., Brooklyn, N. Y., died August 3. He was a graduate of New York University of the class of 1861.

DEATHS ABROAD.

Sir William Stokes, surgeon-in-ordinary to the queen and consulting surgeon to the British forces in South Africa, died at Durban, Natal, August 19, at the age of 61 years. He was the son of Dr. William Stokes, regius professor, Trinity College, Dublin. In 1861 he was awarded the gold medal of the Pathological Society, and in 1864 he was made surgeon to the Meath Hospital. He was examiner in surgery in Queen's University, and had been president of the Pathological Society, the Irish Graduates' Association, and the Royal College of Surgeons. He was a member of numerous medical societies and an extremely prolific contributor to the literature.

Dr. Girard, of Puy de Dome, at the age of 71 years, who was a member of the Chamber of Deputies for several years, and had served in the Riom city council and as mayor from 1863 till 1893.

Dr. Quintaa at Poret, his native town, at the age of 57 years. He was a republican senator from the Basses-Pyrénées, and had represented his province in the national legislature for eleven years.

John Stuart Stevenson, M.R.C.S. Eng., L.R.C.P. Lond., Captain Indian Medical Service, died from heat apoplexy at Lucknow, India, July 20, at the age of 28 years.

Dr. Franz Michl, professor extraordinary of surgery at Prague.

Dr. E. LeGall, who co-operated with Berillon to found the "Institut Psycho-Physiologique" in 1890, has committed suicide. He was a chevalier of the Legion of Honor, 52 years of age and universally respected, but was financially unsuccessful, lived alone and in poverty.

Societies.

Coming Meetings.

American Academy of Railway Surgeons, St. Paul, Minn., Sept. 5-6.

American Association of Obstetricians and Gynecologists, Louisville, Ky., Sept. 18-20.

Medical Society of the State of Pennsylvania, Wilkesbarre, Sept. 18.

Medical Society of the Missouri Valley, Council Bluffs, Ia., Sept. 20.

American Electro-Therapeutic Association, New York City, Sept. 25-27.

American Public Health Association, Indianapolis, Ind., Oct. 2-5.

Idaho State Medical Society, Boise, Oct. 4-5.

Utah State Medical Society, Salt Lake City, Oct. 4-5.

Wyoming State Medical Society, Cheyenne, Oct. 9-10.

Mississippi Valley Medical Association, Asheville, N. C., Oct. 9-11.

Tri-State Medical Society of Alabama, Georgia and Tennessee, Chattanooga, Tenn., Oct. 9-11.

Vermont State Medical Society, Rutland, Oct. 11-12.

New York State Medical Association, New York City, Oct. 16-18.

Medical Society of Virginia, Charlottesville, Oct. 23.

The Delaware County (Pa.) Medical Society held a meeting in Chester, August 9, at which Dr. Thomas C. Stellwagen, Jr., of Media, read a paper on "Blood Examinations."

The Medical and Surgical Society of Southwestern Illinois convened in Jerseyville, August 3, Dr. Edward L. H. Barry read a paper on "Pneumonia." Dr. Carl Black, Jacksonville, also read a paper.

The Jackson County (Ind.) Medical Society met at Seymour, August 8. Dr. J. K. Ritter read a paper on "Medical and Surgical Diseases of the Rectum," which was followed by a general discussion.

The Breckenridge County (Ky.) Medical Society was organized early in August, at Hardinsburg. Dr. R. T. Dempster, Glendeane, was elected president, and Dr. Milton Board, Jr., Hardinsburg, secretary. Smallpox was the subject discussed at the initial meeting.

The Madison County (Ala.) Medical Society held its regular meeting at "Doctors Home," Huntsville, President J. P. Burke, Meridianville, in the chair. The discussion of the day was on "Summer Diarrhea of Infants." Dr. B. E. Graham, Gurley, presented a paper on this subject.

The Williams County (Ohio) Medical Association was organized at Montpelier, August 9, and will hold monthly meetings. Officers elected are: Dr. H. W. Wertz, Montpelier, president; Dr. T. E. Schrider, Bryan, vice-president; Dr. Warren L. Hogue, Montpelier, secretary, and Dr. L. A. Beard, Pioneer, treasurer.

The Jo Daviess County (Ill.) Medical Society met in Galena, July 25, for its second annual session. After a short business session, the society adjourned to the Grant Hotel, where it was entertained by the president, Dr. H. T. Godfrey.

The Muskingum County (Ohio) Medical Society met at Zanesville, August 9. Dr. C. M. Lenhart read a paper on "Fracture of the Neck of the Femur in the Aged;" Dr. J. M. Fassig, a paper on "Whooping Cough," and Drs. E. C. Brush and E. C. Logsdon reported cases.

The Morgan County (Ill.) Medical Society convened for its regular monthly meeting at Jacksonville, August 9. Dr. Moffett read a paper on "Acute Miliary Tuberculosis." Miss Abbie Pierson, through the secretary, Dr. Carl E. Black, presented the society with some valuable books and manuscripts.

The Susquehanna County (Pa.) Medical Society met at Heart Lake, August 7, Dr. C. W. Caterson, Franklin Forks, presiding. The delegates to The American Medical Association made their reports, and several cases were reported and discussed.

The Wabash County (Ill.) Medical Society held its annual meeting in Mount Carmel, July 31, and elected the following officers: President, Dr. Norman Leeds, Bellmont; vice-president, Dr. Jacob Schenck; secretary, Dr. John B. Maxwell, and treasurer, Dr. George C. Kingsbury, all of Mount Carmel.

The Union Medical Association of Northeastern Ohio held its 116th quarterly session at Massillon, August 14, at which Dr. Joseph F. Hobson, Cleveland, read a paper on "Fractures of the Pelvis With Injuries of Its Contents," and Dr. E. O. Leberman, Akron, read one on "Treatment of Certain Skin Diseases."

The Fairfax (Va.) Medical Society, at its annual meeting, August 7, elected the following officers: President, Dr. T. M. Lynch, Annandale; vice-president, Dr. James T. Jones, Ashburn; secretary, Dr. George B. Fadeley, Falls Church; treasurer, Dr. Edwin L. Detwiler, Herndon, and corresponding secretary, Dr. Frederick M. Brooks, Swetnam.

The Keokuk County (Iowa) Medical Society met at Sigourney, August 8. Papers were read by Miss M. Sherlock, on "Trained Nurses;" Dr. L. B. Oliver, on "Prostatic Enlargement;" Dr. J. C. Williams, on "Smallpox;" and Dr. C. J. Lukens, Oskaloosa, on "Simple Eye Diseases Encountered by the General Practitioner."

The Muscatine County (Iowa) Medical Society met, August 9, at Wilton for its regular quarterly session, Dr. Henry Munson Dean, Muscatine, in the chair. Papers were read by Dr. George Morgridge, Muscatine, on "Inflammation" and by Dr. H. Johnson Dean, Muscatine, on "Injuries of the Cornea," and several interesting cases were reported.

The Washington County (Pa.) Medical Society met at Washington, August 14, President Dr. J. B. Irwin, Washington, in the chair. The subject for discussion was "Diarrheal Affections of Summer," and papers were read by Dr. W. V. Riddle, Burgettstown; O. P. Dearth, Washington; W. H. Alexander, Canonsburg; F. C. Stahlman, Zollarsville, and N. S. Veatch, California.

The Chambers County (Ala.) Medical Society held a meeting, July 26, at Lafayette. Hon. A. J. Driver, Jr., delivered an address on "Chambers County and Her Medical Profession," and State Health Officer Dr. W. H. Sanders, Montgomery, an address on "Importance and Duties of County Health Officers." Dr. W. H. Hudson read a paper on "Appendicitis," and Dr. W. D. Gaines one on "Typhoid Fever."

The Fort Dodge (Iowa) District Medical Society met in Webster City, August 14. Papers were read by Dr. A. G. Shillito, Independence, on "Appendicitis;" Dr. C. W. Rummel, Webster City, on "Exophthalmic Goiter;" Dr. Matthew D. Mann, Buffalo, N. Y., on "Some Common Mistakes in Gynecological Practice;" Dr. A. M. Pond, Webster City, on "Drainage;" Dr. C. H. Churchill, Fort Dodge, on "Two Surgical Cases," and Dr. G. A. Geist, Stanhope, on "Hypnotism and Applied Therapeutics."

The Cayuga County (N. Y.) Medical Society met in Auburn, August 8. The committee reported on "Public Danger from Distribution of Samples of Poisonous Medicine in Advertising." Papers were read by Dr. George Slocum, Genoa, on "Observations of the Scarlet Fever Epidemic of Spring of 1900;" Dr. Charles L. Lang, Meridian, on "Pine Bluff, N. C., as a Health Resort," and Dr. B. C. Loveland, Syracuse, on "Treatment or Care of Functional Nervous Disease." Dr. Amelia W. Gilmore, Auburn, made an appeal for a public medical library, and Prof. James Law, of Cornell University, delivered an address on "Rabies and Hydrophobia."

The Medical Section of the National Fraternal Congress will meet in Boston, August 27. The program includes the address of the president, Dr. R. E. Moss; committee reports by Drs. Moss, Millman and McCollom on "Height and Weight," and by Drs. McCollom, Moss and Grosvenor on "Mortality from Cancer and Consumption;" also papers by Dr. J. Millman on "Result of Correspondence With Medical Examiners;" Dr. E. Francis Morrill, on "Appendicitis from an Insurance Standpoint;" Dr. A. H. Warner, on "How We May Secure Better Medical Examinations"; Dr. J. O. Davis, on "The Local Examiner and His Responsibility," and Dr. Mary Danforth, on "Female Risks."

Colorado State Medical Society.

Thirteenth Annual Convention, Denver, June 19-21, 1900.

(Continued from page 449.)

SYPHILIS. MODES OF INFECTION.

Dr. E. P. Hershey, in opening the symposium on syphilis, said that it is astonishing that this loathsome disease does not spread more among the innocent than it does, through the carelessness displayed by those who are afflicted. Syringes, money, cigar-cutters, lead pencils, soap, towels, and drinking cups have all been responsible for the inoculation of the innocent. It is the duty of every physician to warn his patient not to trust too implicitly in the purity of his neighbor.

PROBLEMS OF DIAGNOSIS OF INITIAL SYPHILITIC LESIONS.

Dr. W. B. Davis said that the differential diagnosis is to be made from chancroid, herpes progenitalis, gumma, epithelioma and lupus vulgaris. Between chancre and chancroid, differentiation is not always satisfactory, even after careful consideration of established points of contrast; and a degree of uncertainty will continue to linger until the bacillus—or whatever it is—of syphilis is discovered. The diagnosis, therefore. should always be given guardedly.

BACTERIOLOGY OF SYPHILIS.

Dr. W. C. Mitchell reviewed the literature on the subject, and came to the conclusion that the question is as far from solution as possible. One of the principal difficulties in the way seems to be the fact that animals are not susceptible to syphilitic virus, thus limiting the experimentation on this subject. He said that almost nothing of importance had been added to the rules formulated by Fernelius some 400 years ago, namely, 1, that the syphilitic virus first infects one portion of the body and then spreads through the entire organism; 2, all the tissues and fluids are finally drenched with the syphilitic poison; 3, that the tissues and fluids are the vehicles of the contagion; 4, that the infection occurs only by direct contact on a portion of the mucous membrane or skin denuded of its epithelium; 5, that syphilis dating from birth has had its origin in the parents; 6, that syphilis may remain latent in the system; 7, that a person suffering from syphilis can not receive a fresh infection.

CUTANEOUS MANIFESTATIONS OF SYPHILIS.

Dr. J. M. Blaine does not attach much importance to the color of syphilitic eruptions. An albino would show a pink lesion, while a negro would present a black one, and the various shades of color would represent the colors of the rainbow. The sensation of burning, stinging, itching and pain so common in most dermatoses are, in almost all cases of syphilis, entirely absent. The earliest skin eruption in secondaries is the erythematous. There is enlargement of the post-cervical and epitrochlear and other glands. The papular syphilid makes its appearance usually about two months after the chancre. It may be mistaken for lichen planus, but the latter shows a tendency to grouping and is rarely found on the palms and soles. There is no condition likely to be mistaken for pustular syphilid unless it is on the face, chest and back, in which case one might think of acne vulgaris. Acne comes about the age of puberty, and is always associated with comedones. Pigmentary syphilid is not influenced by syphilitic treatment; it disappears of its own accord. Papulo-squamous syphilid may closely resemble lupus erythematosus and psoriasis. Lupus is a disease of slow progress, and occurs about the nose and cheek; the syphilid occurs on the face. Psoriasis when removed shows a bleeding surface, and decided preference for extensor surfaces, and soon develops into larger, scaly patches. There is no other condition for which tubercular syphilid could be mistaken if the central cicatrix is carefully observed.

SYPHILIS OF THE BRAIN.

Dr. J. T. Eskridge in discussing this subject said that acquired syphilis of the brain is found nearly three times more frequently in the male than in the female. The proportion of syphilitics manifesting brain symptoms is between .5 and 1.5 per cent. The time between the primary lesion and the appearance of brain symptoms is variable and indefinite. There are the so-called precocious cases in which the brain symptoms appear within the first year of the infection. He has seen a young man with syphilitic derangement of the cerebral arteries, who was stricken down with apoplexy three months after the initial lesion. At no time can it be asserted that the danger of brain lesion is passed. Chronic alcoholism renders the brain vulnerable to the poison of syphilis. Only the specific lesions, those that occur as a direct result of the poison of syphilis, are especially amenable to antisyphilitic treatment, while the numerous injuries caused by the presence of specific lesions, or the degeneration resulting from toxemic or other blood states which may result from syphilis, are in no way specific in character, and respond tardily to antisyphilitic treatment, as do the lesions resulting from causes wholly unassociated with syphilis. Gummata vary in size from a line to several inches in diameter, the tendency being to degenerate, and they may be single or multiple. If appropriate treatment is instituted early, before caseous fibroid degeneration takes place, the whole morbid process may be removed and a cure, so far as local brain trouble is concerned, may be complete. He has not met with a case of venous hemorrhage due to syphilitic degeneration of the vessel.

One of the marked features of syphilis of the nervous system is the irregularity and multiplicity of the symptoms. Headache is a prominent one, as is also insomnia, or when pressure is present, somnolence. Jacksonian epilepsy or mental defect is present, according to the site of the lesion.

It is a common occurrence that in a few hours, or a day or more after the development of pronounced paralysis in syphilitic subjects, the limbs may in some cases begin to move at will and soon regain partial or complete power of motion. There are three possible explanations for this phenomenon which is not found in hemorrhage, thrombus or embolism: 1. A small vessel has been occluded, though on account of the disease of numerous other vessels, the shock has been so great that immediate and almost complete paralysis has resulted, but as soon as there is recovery from the shock, collateral circulation is established. 2. The occluded vessel may supply an area just without the motor region, but owing to the crippled state of the general circulatory brain apparatus, function is temporarily lost in the adjacent or motor area. 3. The collateral vessels to the affected area are diseased but their calibers are not occluded. The beginning of mental failure is represented by a group of symptoms—dizziness, absentmindedness, forgetfulness and loss of ambition. At first the patient takes an interest in himself, but as the trouble increases he is apt to become indifferent to his condition, and, if not treated will eventually have dementia. The treatment may be divided into prevention, general management, and antisyphilitic remedies. Active treatment from the outset is the most reliable prophylactic. Potassium iodid in 15-gr. doses three times a day gives the best results; and tonics should not be neglected.

There are numerous non-specific intracranial lesions resulting from specific causes which fail to yield to specific medication. It is pitiable to see a hemiplegic or dement whose helplessness has been caused by thrombotic occlusion of a vessel, indirectly due to syphilis that has been treated by mercury or potassium iodid for months. The profession must learn to treat syphilis of the brain according to the lesion from which the patient is suffering, and have some regard for the patient, notwithstanding that he is so unfortunate as to be the victim of syphilis.

OCULAR MANIFESTATIONS OF SYPHILIS.

Dr. Edward Jackson said that of all the cases of syphilis only 3 per cent. suffer from iritis. Iritis occurs as a tertiary lesion in connection with gumma of the iris, with interstitial keratitis, and without notable lesions of the cornea. Cataract occurs in syphilitics by mere coincidence, sometimes, however, as a result of extensive diseases of the uveal tract, on which the nutrition of the crystalline lens depends. The transparency of the vitreous suffers more frequently. Choroidal lesions are almost always present. Syphilitic retinochoroiditis comes on during the secondary period, optic neuritis and neuroretinitis are sometimes tertiary lesions. Tarsitis, dacryoadenitis and gumma of the orbit also occur; and 60 per cent. of palsies of the ocular muscles are due to syphilis.

(To be continued.)

Therapeutics.

Treatment of Headache.

Prof. J. C. Wilson, of Philadelphia, gives the following classification for the ætiological causes of headache:

1. *Reflex Irritations.*—*a*, the eye; *b*, the nose; *c*, the teeth; *d*, the ear; *e*, the reproductive organs.
2. *Toxemia.*—*a*, infectious diseases; *b*, autointoxication; *c*, drugs—opium, alcohol, quinin; *d*, poisons—lead, tobacco, tea, coffee.
3. *Disturbance of Circulation.*—a, congestions; b, anemia; *c*, arterial changes.
4. *Neuroses.*—*a*, epilepsy; *b*, hysteria; *c*, neurasthenia.
5. *Organic Disease.*—*a*, syphilis; *b*, meningitis, etc.

Dr. F. Windscheid, of Leipsic, in an article on headaches, states that in no ailment must the causal indication be so closely adhered to as in headache. Consequently, in outlining the treatment of headache as given in the above classification it will not be possible to deal with each class.

As Dr. Collins states, the treatment of headache accompanying the infectious diseases can best be remedied by combating the cause. The treatment of those arising from drugs consists in the discontinuance of those preparations taken therapeutically—mineral or vegetable—proper care, when required by occupation to come in contact with the metals, such as lead, mercury, etc., and the promotion of the elimination of any poison which may be in the system. But, aside from these cases where the treatment is strictly etiological, there are a variety of idiopathic forms which require special treatment.

HEADACHE OF EYE-STRAIN.

℞. Ext. nucis vomicæ .... gr. viii | 5
Ext. cascaræ sagradæ .... gr. xii | 8
Ext. gentianæ .... gr. xxiv 1 | 50
M. Ft. capsulæ No. xxiv. Sig. One capsule every four hours.

℞. Ext. cimicifugæ fluidi .... ℥i 32 |
Syrupi simplicis, q. s. ad .... ℥iii 96 |
M. Ft. mistura. Sig. One teaspoonful after each meal.

℞. Butyl-chloral-hydratis .... ʒi 4 |
Aquæ cinnamomi .... ℥ii 64 |
M. Sig. One teaspoonful every four hours.

Butyl-chloral-hydrate—croton-chloral—is made by passing a current of chlorin through paraldehyde until saturated. It is soluble in thirty parts of water.

These preparations are indicated only when there are no organic changes in the eyes.

HEADACHE ACCOMPANYING THE MENOPAUSE.

℞. Sodii arsenatis .... gr. i | 06
Ext. cannabis indicæ .... gr. iiss | 15
Ext. belladonnæ .... gr. iv | 25
M. Ft. pilulæ No. xv. Sig. One pill twice daily.

HEADACHE ARISING FROM OVARIAN TROUBLE.

℞. Ammonii bromidi .... ʒiii 12 |
Ext. hydrastis fluidi .... ʒii 8 |
Tinct. gentianæ comp .... ℥iss 48 |
Aquæ destil., q. s. ad .... ℥iv 128 |
M. Sig. One dessertspoonful in water three times a day.

Or,

℞. Ext. cimicifugæ fluidi .... ℥ 32 |
Sig. Twenty drops in water three times a day.

Cimicifuga is especially indicated in neuralgias or headaches of ovarian origin.

HEADACHE AFTER INFECTIOUS DISEASES.

℞. Pulveris opii
Zinci phosphidi, āā .... gr. ss | 033
M. Ft. capsulæ No. xx. Sig. One capsule three times a day after meals. —*Collins.*

Or,

℞. Ferri et ammonii citratis .... gr. xl 2 | 66
Liquoris potassii arsenitis .... m. xl 2 | 66
Syrupi zingiberis .... ℥ss 16 |
Infusi calumbæ, q. s. ad .... ℥iv 128 |
M. Sig. Two teaspoonfuls after each meal in water.

For adults, Dr. Collins prefers liquoris ferri et ammonii acetatis—Basham's mixture—to the citrate.

HEADACHE OF ATONIC DYSPEPSIA WITH LITTLE FLATULENCY.

℞. Sodii arsenatis .... gr. i | 06
Quininæ sulphatis
Ferri sulphatis, āā .... gr. xl 2 | 66
Pulveris rhei.
Pulveris zingiberis, āā .... gr. xx 1 | 33
M. Ft. capsulæ No. xx. Sig. One capsule after each meal.

HEADACHE ASSOCIATED WITH FLATULENCY.

℞. Sodii bicarbonatis
Bismuthi subgallati
Pulveris acaciæ, āā .... ʒi 4 |
Aquæ menthæ pip .... ʒii 8 |
Aquæ destil., q. s. ad .... ℥viii 256 |
M. Sig. Shake. Two teaspoonfuls before each meal.

RHEUMATIC HEADACHE.

℞. Potassii iodidi
Sodii salicylatis, āā .... ʒii 8 |
Vini pepsini, q. s. ad .... ℥iii 96 |
M. Sig. One teaspoonful three times a day after meals.

℞. Ext. colchici .... gr. v | 33
Ext. digitalis .... gr. iv | 25
Quininæ valerianatis .... gr. xxiv 1 | 50
M. Ft. capsulæ No. xv. Sig. One capsule four times a day.

℞. Chloralis hydratis
Camphoræ
Olei cajuputi, āā .... ℥i 32 |
M. Sig. Apply locally for the relief of pain in rheumatic or neuralgic headache.

RHEUMATIC HEADACHE.

℞. Salipyrini .... ʒii 8 |
Ft. pulveres No. xii. Sig. One powder three times a day.

Salipyrin is composed of antipyrin 42.3 parts and salicylic acid 57.7 parts, therefore it exerts the combined effects. It is soluble in 200 parts of cold water. Reliable authorities state that salipyrin does not produce the bad effects that follow the administration of other similar preparations.

HEADACHE OF GOUT WITH ANEMIA.

℞. Sodii salicylatis .... ʒiv 16 |
Glycerini .... ℥ii 64 |
Olei gaultheriæ .... m. xx 1 | 33
Tinct. ferri chloridi .... ʒiv 16 |
Acidi citrici .... gr. x | 66
Liquoris ammonii acetatis, q. s. ad ..... ℥iv 128 |
M. Sig. One dessertspoonful three times a day in water. —*Solis-Cohen.*

GOUTY HEADACHE WITH ANEMIA.

℞. Acidi salicylici
Ferri pyrophosphatis, āā .... ʒi 4 |
Sodii phosphatis .... gr. xii | 72
Aquæ destil., q. s. ad .... ℥vi 192 |
M. Sig. One tablespoonful in water. —*Peabody.*

℞. Vini colchici seminis .... ℥ss 16 |
Potassii acetatis
Potassii iodidi
Tinct. cimicifugæ, āā .... ʒv 20 |
Aquæ destil., q. s. ad .... ℥iv 128 |
M. Sig. One teaspoonful every four hours. —*Hare.*

In gouty headache colchicum can be employed with greater freedom, care being taken to keep the bowels freely open.

GOUTY HEADACHE.

℞. Sodii iodidi
Vini colchici, āā .... ʒiii 12 |
Ext. cimicifugæ fluidi
Tinct. guaiaci ammoniatæ
Ext. cocæ fluidi, āā .... ʒvi 24 |
M. Sig. One teaspoonful after each meal, in water.

HEADACHE OF UREMIA ACCOMPANYING CHRONIC INTERSTITIAL NEPHRITIS.

℞. Potassii citratis.
Tinct. hyoscyami.
Spiritus ætheris nitrosi, āā .... ʒiv 16 |
Infusi scoparii, q. s. ad .... ℥iii 96.
M. Sig. One tablespoonful three times a day, in water. —*Collins.*

℞. Potassii acetatis	ʒvi	24	
Infusi digitalis	℥vi	192	

M. Sig. One tablespoonful in water every five or six hours. This is indicated in headaches accompanying Bright's disease with low arterial tension. Remember that the effect of digitalis upon the heart and arterial system lasts for five or six hours.

BILIOUS HEADACHE.

℞. Tinct. nucis vomicæ	℥ss	16	

Sig. One drop in water every ten minutes until twelve drops are taken. —*Ringer.*

℞. Sodii phosphatis efferv.	℥ii	64	

Sig. One teaspoonful one hour before breakfast, in water.

PLETHORIC HEADACHE.

℞. Tinct. ferri chloridi	ʒii	8	
Acidi hydrochlorici diluti	ʒss	2	
Tinct. cinnamomi			
Syrupi simplicis, āā	ʒvi	24	
Aquæ cinnamomi, q. s. ad	℥iii	96	

M. Sig. One teaspoonful one-half hour after eating, three times a day.

℞. Olei eucalypti	ʒii	8	

Sig. Five drops every four hours as a preventive or during the attack.

Eucalyptus has been highly recommended in this form of headache where the coal-tar products have seemed deficient or non-indicated.

CONGESTIVE HEADACHE.

℞. Tinct. aconiti	gtt. viii		4
Aquæ destil.	℥ii	64	

M. Sig. One teaspoonful every hour until headache is relieved.

℞. Ext. ergotæ fluidi	℥i	32	
Potassii bromidi	ʒii	8	
Elixiris simplicis, q. s. ad	℥iii	96	

M. Sig. One teaspoonful in water three times a day.

℞. Tinct. belladonnæ	℥ss	16	

Sig. Six drops every three hours in water. —*Ringer.*

SALINE DIURETIC IN PLETHORIC HEADACHE.

The following is recommended as a saline diuretic in plethoric headache:

℞. Potassii acetatis	ʒii	8	
Potassii nitratis	ʒi	4	
Spiritus juniperis comp.	ʒx	40	
Aquæ menthæ pip., ad	℥iv	128	

M. Sig. One teaspoonful twice daily, followed by an aperient at night.

HYSTERICAL HEADACHE.

℞. Zinci valerianatis	gr. xii		75
Ext. belladonnæ	gr. iv		25
Ext. gentianæ	gr. xxiv	1	50

M. Ft. capsulæ No. xii. Sig. One capsule three times a day.

℞. Tinct. valerianæ			
Spiritus ætheris comp.			
Spiritus lavendulæ comp., āā	ʒiii	12	
Tinct. hyoscyami	ʒii	8	
Aquæ camphoræ, q. s. ad	℥iv	128	

M. Sig. One tablespoonful three times a day.

℞. Tinct. valerianæ ammoniatæ			
Spiritus ætheris comp., āā	ʒiii	12	
Aquæ camphoræ, q. s. ad	℥ii	64	

M. Sig. One dessertspoonful twice or three times a day.

NEURALGIC HEADACHE.

Subjects of neuralgic headache are very anemic as a rule and require diet and rest.

For this form of headache the following prescriptions are recommended:

℞. Ferri sulphatis—exsiccated			
Potassii carbonatis—exsiccated—āā	ʒi	4	
Ext. nucis vomicæ	gr. viiss		5
Acidi arsenosi	gr. i		06

M. Ft. capsulæ No. xxx. Sig. One capsule after each meal, three times a day.

℞. Tinct. nucis vomicæ	ʒiv	16	
Liquoris potassii arsenitis	ʒi	4	
Aquæ camphoræ, q. s. ad	℥ii	64	

M. Sig. One teaspoonful after each meal, in water.

FOR THE PAIN IN NEURALGIC HEADACHE.

℞. Kryofin	ʒi	4	

Ft. capsulæ No. x. Sig. One capsule every three or four hours until pain is relieved.

This preparation is closely allied to phenacetin and should be discontinued when the pain has stopped.

SICK HEADACHE.

℞. Methylene blue			
Pulv. myristicæ—nutmeg—āā	gr. xxx	2	

M. Ft. capsulæ No. xx. Sig. One capsule four times a day.

Very favorable reports have been published pertaining to the use of methylene blue in the treatment of headache. The nutmeg is used in combination with it on account of its stomachic qualities and its good effect on the bladder.

NERVOUS HEADACHE.

℞. Potassii bromidi	ʒii	8	
Spiritus ammoniæ aromatici, q. s. ad	℥i	32	

M. Sig. One-half teaspoonful every four hours, in water.

℞. Tinct. hyoscyami			
Spiritus ammoniæ aromatici, āā	℥ss	16	
Syrupi aurantii corticis	℥i	32	
Aquæ menthæ pip.	℥ii	64	

M. Sig. One tablespoonful three times a day.

℞. Camphoræ monobromatæ	gr. xv	1	
Acetanilidi	gr. xlv	3	
Caffeinæ citratæ	gr. x		66

M. Ft. capsulæ No. xv. Sig. One capsule every four hours.

℞. Antipyrini	ʒi	4	
Potassii bromidi	ʒiii	12	
Syrupi aurantii	ʒv	20	
Aquæ destil., q. s., ad	℥ii	64	

M. Sig. One teaspoonful every three hours until relieved of the headache.

℞. Caffeinæ citrate	gr. xv	1	
Ammonii carbonatis	gr. xx	1	
Elixiris guaranæ, q. s. ad	℥ii	64	

M. Sig. One dessertspoonful every hour until pain is relieved.

Guarana contains guaranin as the active principle, which is identical with caffein.

NEURASTHENIC HEADACHE.

℞. Zinci valerianatis			
Ferri sulphatis			
Ext. rhei			
Asafetidæ, āā	gr. xviii	1	20

M. Ft. pilulæ No. xx. Sig. One pill three times a day.

℞. Ferri lactatis	ʒi	4	
Ferri citratis	gr. v		33
Ext. nucis vomicæ	gr. x		66
Ext. gentianæ	gr. xxv	1	50

M. Ft. pilulæ No. l. Sig. Two pills three times a day.

℞. Ferropyrini	ʒii	8	

Ft. capsulæ No. xx. Sig. One *capsule three times a day.*

Ferropyrin is a compound of antipyrin 64 per cent., iron 12 per cent., and chlorin 24 per cent. It is soluble in five parts of water, and is indicated in headaches with anemia present.

℞. Potassii bromidi	ʒi	4	

Ft. chartulæ No. vi. Sig. One powder to be taken in seltzer water two or three times a day.

As a *tonic in headache of neurasthenia, the following* has been recommended:

℞. Tinct. nucis vomicæ	ʒiv	16	
Tinct. cinchonæ comp.	℥i	32	

M. Sig. Fifteen or twenty drops in water after each meal.

℞. Zinci phosphidi	gr. iss		09
Ferri redacti	gr. xxiv	1	50
Ext. nucis vomicæ	gr. vi		40

M. Ft. capsulæ No. xxiv. Sig. One capsule after each meal.

HEADACHE IN BRAIN SYPHILIS.

℞. Tablets hydrarg. chlor. corros., āā....gr. 1-25 |0027
No. xv. Sig. One tablet hypodermically daily.

℞. Potassii iodidi
Aquæ destil., āā........................℥i 32|

M. Sig. Ten drops after each meal, in water, and gradually increase to the limit of tolerance.

Sodium, ammonium or strontium iodid can be substituted for the potassium if necessary.

℞. Pilulæ hydrarg. iodidi flavi, āā........gr. 1-5 |012
No. xxiv. Sig. One pill three times a day.

Medicolegal.

Damages Awarded for Fracture of Ribs.—The second appellate division of the Supreme Court of New York holds, in the case of Keiffert vs. the Nassau Electric Railroad Company, that $2,500 could not be considered an excessive award of damages for a fracture of three ribs, resulting in an adhesion which would permanently limit the injured party's power of respiration, and consequently his capacity for labor, it being shown that he was able to earn $11 a week before the accident, and only $9 a week after it.

Ten Thousand Dollars for Injury, Mainly Nervous.—A child 5 years of age was injured, while on the street, by a passing team. According to one of the medical witnesses, there was a concussion of the spine, and injuries to the bladder, resulting in chronic cystitis. His opinion was that the spinal trouble was permanent, but he did not say that the cystitis would be. At the time of the trial, her walk was referred to as a shuffling one, indicating a loss of control of the muscles, or nervous shock and hysteria, as it was variously described, with some other indications of nervous disorder. For such injuries, the second appellate division of the Supreme Court of New York holds in McTague vs. Dowst, $10,000 was not an excessive award of damages.

Approves of Removing Cause of Malarial Fever.—The Supreme Court of the United States says, in the case of Leovy vs. United States, that it thinks a court might well take judicial notice that the public health is deeply concerned in the reclamation of swamp and overflowed lands. If there is any fact, it goes on to state, which may be supposed to be known by everybody, and therefore by courts, it is that swamps and stagnant waters are the cause of malarial and malignant fevers, and that the police power is never more legitimately exercised than in removing such nuisances. Nor does it consider that, because a person has acted under an order of local authorities which did not say anything about the subject of health, as where, for example, such an order simply authorized the erection of a dam, so as to exclude the overflow from a river, that he is therefore to be deprived of the defense to his act that he performed it in order to promote the health of the community, as where the general government charged him with building a dam across a navigable stream without the permission of the Secretary of War.

Reduces Allowance for Injury to Hand.—A young man of about twenty years of age had his left hand injured on a machine which he was operating. He lost the whole of the first or index finger. The first and second joints of the second finger were injured permanently, so that the only use he could have of it would be to "push it down," as it was said. Besides, the first and second joints of his thumb were so injured that motion was considerably limited in the first joint, and partially so in the second joint. But the expert evidence was that the thumb would probably get somewhat better. The jury awarded him $4,500 damages. This the trial judge insisted should be reduced to $3,500. And now the Supreme Court of Minnesota thinks that too much, holding, Stiller vs. Bohn Manufacturing Company, that $2,500 [illegible] be sufficient compensation. The question, [illegible] says, was not for what sum of money [illegible] willing to submit to such injuries, but would reasonably compensate the party, so far as money could compensate him, for his injuries, in view of his age, his earning capacity before and after his injury, the disfigurement of his person, and the pain he had suffered.

Restricting Prostitutes to Certain Districts.—The Supreme Court of the United States has been called on, in the case of George L'Hote and the Church Extension Society of the Methodist Episcopal Church vs. the City of New Orleans, its mayor and superintendent of police, to pass, to some extent, on the validity of an ordinance of said city making it unlawful for any public prostitute or woman notoriously abandoned to lewdness to occupy, inhabit, live, or sleep in any house, room, or closet situate without certain prescribed limits in the city, with a proviso that nothing in the ordinance should be so construed as to authorize any lewd woman to occupy a house, room, or closet in any portion of the city. More specifically, the question presented to the court was whether one who may own or occupy property in or adjacent to the prescribed limits, whether occupied as a residence or for other purposes, can prevent the enforcement of such an ordinance on the ground that by it his rights under the federal constitution are invaded. This narrowing of the question is explained, in part, by the court, with perhaps some significance, as due to the fact that no woman of that character was challenging the validity of the ordinance, nor complaining that she was deprived of any personal rights, either as to the control of her life or the selection of an abiding place. In other words, the court points out that the persons named in the ordinance, and against whom its provisions were directed, did not question its validity. Neither, in the second place, did any person owning buildings outside of the prescribed limits complain that he was deprived of a possible tenant by virtue of the ordinance, or say that the abridgement of her freedom of domicile operated to cut down the amount of his rents. Besides, it calls attention to the fact that the ordinance did not attempt to give to persons of such character license to carry on their business in any way they saw fit, or, indeed, to carry it on at all, or to conduct themselves in such manner as to disturb the public peace within the prescribed limits. Under these circumstances, and with nothing in the ordinance to deny the ordinary right of the individual to restrain a private nuisance, the court does not consider it one of which complaint could be made, by such owners or occupants of property as stated, notwithstanding the pecuniary value of their property might be depreciated thereby. The management of those vocations which minister to and feed upon human weaknesses, appetites, and passions, the court continues, comes directly within the scope of what is known as the police power. Obviously, the regulation of houses of ill-fame, legislation in respect to women of loose character, may involve one of three possibilities: 1, absolute prohibition; 2, full freedom in respect to place, coupled with rules of conduct; or, 3, a restriction of the location of such houses to certain defined limits. Whatever course of conduct the legislature may adopt is in a general way conclusive upon all courts, state or federal. It is no part of the judicial function to determine the wisdom or folly of a regulation by the legislative body in respect to matters of a police nature.

Validity of Exemptions in Practice Acts.—In the case of Scholle vs. State, the Court of Appeals of Maryland gives special attention to the contention that the exemptions of the statutes of that State from the burden of obtaining a license to practice medicine invalidate all of the State legislation regulating the practice of medicine. Those to whom the provisions of the latter do not apply, by reason of these exemptions, are: 1, commissioned surgeons of the United States army and navy and marine hospital; 2, physicians and surgeons in actual consultation from other States; and 3, persons temporarily practicing under the supervision of an actual medical preceptor. The argument advanced was that these exemptions were an unjust and unreasonable discrimination [illegible] persons [illegible]g in the practice of medicine, and [illegible] lit[illegible]aranteed by the 14th amendment [illegible] United States. In answer, [illegible] surrounding all persons [illegible] would be no differences made as to the terms upon which a certificate could be obtained. But if there are differences as to conditions and situations, by which it becomes reasonable that greater precautions are required in some cases than in others, classes may be formed by which certificates can be granted to some without examination, and by which others may be exempted altogether from the burden of being registered. But these classes must be created upon considerations only that are promotive of the public interests. If they are so created, they do not constitute an unlawful discrimination, and do not impair the "equal right which all can claim in the enforcement of the laws." And the reasons for the exemptions in question the court thinks are apparent, and are entirely of a public character. The competency of the first class is assured by the exactions required of them before they become commissioned in the service of the United States as physicians or surgeons. So, also, physicians in a marine hospital are selected for their special adaptation and skill for that work. There could be no public reason, therefore, that these medical officers should be required, for the protection of the public, to be registered. Nor can any reason having in view the public protection be assigned for requiring certificates of the remaining classes. Neither of these classes can be said to be practitioners within the state of Maryland. The physician from another state, "in actual consultation," has co-operating with him a registered physician. To require him to license as for general practice would have no other effect than occasionally to deprive the patient and the local physician of the benefit of the advice of some of the most eminent and skillful gentlemen of the profession. Moreover, as to both the second and third classes, the public are fully protected from the incompetency of the foreign physician and the student by the presence and supervision and restraints of the certified physicians of the state. Hence, the court concludes, there can be no objection to these exemptions as in any respect arbitrary or unreasonable, or as in any manner creating any unjust discrimination. Neither does it consider it a valid objection that one of the bodies charged with the duty of appointing one of the boards of medical examiners is the Medical and Chirurgical Faculty of the State of Maryland—a private corporation.

3. **Acute Influenzal Dilations of the Heart in Children.**—Four cases are reported by Forchheimer, in all of which the direct cause of the trouble appeared to be heart strain. In two of these there was a predisposing weakness of the myocardium. He thinks we are justified in assuming two forms of heart dilation in influenza: 1. A form produced primarily by action of toxins on the nervous system or heart, and possibly on the myocardium. 2. A form occurring in such conditions in which the outflow of blood is materially interfered with by mechanical conditions. The first form may terminate fatally, but in his own experience it was not the case. The second form is more permanent, but in children generally tends to recover.

4. **Military Surgery.**—Borden describes the different arms used in military operations and shows that it is probable that as many deaths on the battlefield will occur with modern weapons as with the ones of the past. The mortality of the wounded, however, will be greatly lessened by the small-caliber, modern, small-arm projectile, which produces over 90 per cent. of the injuries in war. The special disturbing effect of this bullet in passing through fluids or semi-fluids in confined spaces, its action on the bones, etc., are all discussed and illustrated.

5. **Tuberculosis.**—The veterinarian of the Iowa State Agricultural College, Dr. Repp, reviews the literature as to infection, experimentally and clinically, by tuberculous meat and milk, and argues that the transmission to man has been sufficiently proved, giving all the facts that he has been able to collect on the subject. They are not nearly as numerous as the experimental ones of transmission from animal to animal, but he sums up his evidence as follows: 1. That tuberculosis may be transmitted to animals through their eating the meat of certain other animals which are tuberculous or by their being inoculated with it. 2. That tuberculosis may be transmitted to animals through their ingestion of the milk of certain cows which are tuberculous, or by their being inoculated with it, both when the udder of the cows is diseased and when it is healthy. 3. That, therefore, the meat and milk of certain tuberculous animals contain living, virulent tubercle bacilli. 4. That the tubercle bacilli of cattle are pathogenic for man. 5. That, therefore, the meat and milk of certain tuberculous animals have a tendency to produce tuberculosis in human beings who use these products as food. 6. That there is *no evidence that the converse of these conclusions is true.*

9.—See The Journal, xxxiv ¶ 23, p. 1462.

10.—**After-Pain from Tooth Extraction.**—Isaacson thinks that the painful sensations often felt after tooth extraction are due to retention of the pyogenic membrane, expansion of the osseous walls, fracture of the alveolus, retention of the root and spicule, and special conditions due to inflammation and suppuration. He uses the burr to take out the root when it can not be reached by the forceps or is too small, and the use of ethylic chlorid or cocain injection rather than nitrous oxid, which is too temporary in its effects. The chief point of his paper is that these pains are nearly always caused by foreign substances and that removal is preferable to any local treatment that can be used.

11. **Vaccination Eruptions.**—According to the statistics of the dermatologic clinic at the Good Samaritan Dispensary at New York, Sobel finds that about 14 per cent. of the cases present complications or sequelæ and about 2 per cent. generalized eruptions. The most common, generalized eruption was found to be urticaria, sometimes combined with contagious impetigo due to scratching. These urticarial lesions occurred as early as the third or fourth days after inoculation. The morbilliform type, though not very frequent, occurred in several instances, usually ten or eleven days after vaccination. The eruption was differentiated by the history of sudden onset and early disappearance of the rash with desquamation within forty-eight hours. In two or three instances he says he observed conditions very closely resembling rötheln. Of the vesicular eruptions some simulated chicken-pox very closely. He thinks it possible that it may have been complicated with that disease. General scarlatiniform eruptions or pustulobullous lesions were several times entered on the records. Some cases suggested syphilis, others echthyma, conjoined, erythema multiforme and papulo-vesicles, scarlatina, erythema and minute vesicles, urticaria and erythema multiforme, were also met with.

12. **Arsenic in Chronic Enteritis.**—Kolopinski advises the use of arsenic in small doses—1/64 to 1/32 gr.— hypodermically in 60 minims of normal salt solution. This treatment must be associated with regulated diet, excluding desserts. fruits and preserves and allowing milk, cocoa, chocolate, etc. Favorable results are in all cases most certain to be attended by exclusive diet of milk and cocoa. The good effects of treatment are not always certain and he has had some non-successes. On the whole, however, he concludes that this method is safe, painless and effective. The dose is very small, as given above. One, two or three injections per week will cure the milder cases. Other internal medication is avoided and the patient has no daily routine of dosing. Greater latitude of diet can be allowed without detriment.

13. **School Break-Down.**—Noticing a rather sensational article in a lay journal Bartlett analyzes the facts in regard to school break-down in a conservative way. He thinks the assumption that so large a number of cases are due to overstudy is not warrantable and points out other practices and habits that have much to do with the trouble. Most all of these cases occur during the developmental periods. The development processes are more to blame than overstudy. Errors of diet, sleep, etc., are mentioned as probable causes. He thinks that the strain of examinations and pressure of unnatural stimuli in school life are against a rational school system and not the fruits of it, and that we should study the subject of adolescence rather than try to bring about a revolution in our school practice.

13. **The Automobile in Country Practice.**—Dr. Hard, who has the degree of M.E., as well as M.D., notices the different types of the automobile as adapted to the country doctors' use. The electric motor he rejects on account of its weight, limited radius of action and unsuitability to country roads. The hydrocarbon system has the similar disadvantages of weight, unsuitability to country roads and is also disabled in very cold weather. When it breaks or sticks it is almost impossible to get it to work again. It has some good features. It does not depend on an independent power-plant; its expense is slight; it can be left safely standing and does not leak power when it is not in use like the electric vehicle. There is but little danger connected with its use and its manipulations is easily learned by the average individual. The steam-driven carriage is the one with which he has had the best results, but it requires a skilled mechanic. If it breaks down in one part the whole is disabled. The boiler is constantly trying to commit suicide and it is difficult sometimes to keep up steam. Cold weather interferes with the steam production. Unless a careful selection of water is made the boiler foams and blows out its flues. The machinery is all exposed to the dust and it can not be left standing, as it will noisily blow off steam, and if the fire is turned out it takes time to start it. Is advantages are: that it is is more powerful, has a wider radius of action and can be watered as conveniently as a horse. Many of the defects admit of correction, and when a steam generator is put into use which instantly converts into steam small and variable quantities of water so that the power may be produced at will without a reserve supply of water and steam in the boiler there is no apparent reason why all of the objections found in the steam carriage of to-day may not be successfully met.

16. **Uratic Diathesis.**—Croftan reiterates some views formerly expressed as to the non-toxicity of uric acid and the importance of alloxuric bases as the peccant material in so-called uric acid poisoning. These, he thinks, are derived from the nuclein of the white corpuscles and are the results of an inincreased nuclein catabolism. The practical therapeutic points to be looked after are: 1, increased limitation of the toxins as they are formed; 2, to reduce the nuclein catabolism; 3, to increase the processes of oxygenation. The use of alkalies and dietary regulations have proved of value. The alkalies produce an increased elimination of the uric acid and alloxuric bases. The diet, which has been variously handled heretofore, should be such as to exclude the nuclein-containing substances as far as possible, especially those forms that are liable to produce the alloxuric bases, the interdiction of alcohol and tea. The raising of the oxygenation power of the cells can be obtained by a general tonic treatment according to individual needs. Here also massage, hydrotherapy, electrotherapy, etc., have a field. The importance of increased oxidation is to be shown by the benefit produced in uratic cases by oxygen inhalations, and the author gives a tabulated statement of the urine constituents before and after oxygen inhalation in several cases as illustrating this point.

17. **Diphtheria.**—Robin replies to the recent paper of Dr. Herman that antagonizes the antitoxin therapeutics. This article is largely a statistical one and is very severe in its criticisms of Herman's methods and ideas. He shows apparently conclusively that antitoxin is a valuable resource in therapeutics and sums up his paper by giving the necessary qualities of a specific and its action. Antitoxin, he says, cures every case of experimental diphtheria in which the amount of toxin is known. It cures from 75 to 90 per cent. of all cases of human diphtheria in which the amount of toxin circulating in the blood is not known. It reduced the mortality to 10 to 15 per cent., the lowest point ever recorded throughout extensive areas, and has kept it there since 1894. It does the work without the addition of any other medication, although in man symptoms are usually combated with drugs.

19. **Seminal Vesiculitis.**—Impotence, according to Guiteras, is largely due to inflammation of the seminal vesicles, though there may be other predisposing causes such as chronic inflammation of posterior urethra, chronic prostatitis, varicocele, etc. He reports cases illustrating his views and the treatment of the condition, which is a sedative one, at first avoiding anything that is stimulating or exciting in the sexual sphere, with internal remedies to neutralize the urine in case of over-acidity. He uses rectal irrigation every night, with normal salt solution or strained flaxseed at a temperature of 105 to 120 F., by means of the double-current rectogenital tube and massage of the internal genitals every five days followed immediately by urethral irrigation whenever there is chronic prostatitis and posterior urethritis associated with the condition. After the irritation and inflammation have been removed, stimulation by drugs, electricity, and regulation of hygiene is employed.

21. **Insufflation of Stomach and Colon.**—Spivak describes his method of stomach insufflation as well as that of the colon and esophagus, and discusses its diagnostic importance. The

therapeutic uses of the method are also noticed. He is experimenting at present with insufflation of hot air in the stomach in various gastric disorders, but does not wish to report premature conclusions. He suggests the use of insufflation as a means of pushing down foreign bodies in the esophagus as less dangerous and forcible than the use of the bougie. He will also use insufflation in his next case of esophagismus.

27. Alcohol as a Food.—Cuzner reviews the facts and theories as to the food value of alcohol, with special reference to the recent statements of Prof. Atwater and the contradictory ones that have since been published. He holds that while Atwater is probably understood by the medical profession, to the public his statement appears as an endorsement of the dietetic use of alcohol, but that he will himself agree with the statement that it is only a food to a very limited extent and not properly one in a general sense, and that it is more properly classed as a narcotic poison. Cuzner maintains that we must still keep it in the list of the latter and not admit it in any way to the category of alimentary substances.

30. Urine from Ureters.—Harris discusses the different instruments for collecting urine, showing their advantages and disadvantages. In considering catheterization of the ureter he points out that it requires a sufficient transparency of the media for its use, which is not by any means always insured, and that the extravesical conditions such as displacements by tumors may so distort the base of the bladder as to render the introduction of the catheter impossible. It may become clogged with pus and may produce spasm of the ureter. It is apt to produce a certain amount of mechanical injury; a little blood at first is the rule, and it does not collect all the urine. Another thing to be considered is the danger of infection, in cases of cystitis for example. The segregator requires the same conditions as those requisite for the cystoscope. The bladder must be large enough to allow the instrument to be opened and the ureter must be large enough to admit its introduction. As the sight is not used in guiding it the transparency of the media is not important and conditions within the bladder, such as folding of the mucous membrane, etc., which might interfere with catheterization do not effect its usefulness. Large fibroid growths may prevent its application and great thickening of the trigone so that it can not be raised to form a septum, or where a so-called middle lobe projects into the bladder, displacement or distention may interfere the same as with catheterization. He points out cases illustrating the reliability of the septum produced and he maintains that the bladder can be so cleansed as not to contaminate the urine in its passage from the ureter to the container. It may excite hemorrhage from the bladder wall, but it is an exception if the bladder is healthy. The advantage of the segregator is that all the urine that escapes from the ureters is collected in the vial, none is lost as in the catheter. He does not try to claim that it is always successful and that it can take the place of every other device. It has its limitations, but for differential diagnosis in certain tumors of the abdomen, for determining which kidney is diseased and the functional capacity of each, whether the bladder be affected or not, for differentiating between certain bladder and kidney affections, it gives results that are perfectly reliable, as has been repeatedly demonstrated. Furthermore it is safer than the catheter, as it never infects the healthy kidney.

31. Ureteral Implantations.—This extensive review of the operative procedures in cases of injury to the ureter covers pretty nearly all the published facts. The author describes the different methods of uniting or implanting the ureter. He says it is impossible to have the anastomosis between the ureter and bladder as good as the natural one because the small muscles at the end of the ureters and lost in the wall of the bladder and internal meatus can not be utilized. Whenever the ureter requires grafting above the brim of the pelvis its implantation into its fellow is to be considered, though where this is impracticable loosening of the kidney is the next step, and if this can not be done implantation into the bowel is the next. Rectal implantation is discussed and Bovée thinks that it is probable that the carefully made oblique and longitudinal grafting may have the desired effect, but infection is always to be feared. Where the Maydl and Pozza modifications are practicable in cases of implantation of both ureters they should be used. Skin implantation of the ureter is rather condemned, it is not an alternative for bladder or ureteral anastomosis or even bowel implantation. It may be done in cases of a very short stump when it is impossible to unite the two ureteral ends, but if there be but one kidney, bowel implantation is preferable. Implantation of the ureter into the vagina seems to the author only incurring permanent disability. The urethral grafting of ureters has been done in a few cases, but Bovée believes it has but a limited field and that it is a failure as a substitute for the Maydl operation.

33. Tetanus.—Moschcowitz favors the nerve-transmission theory of tetanus, though he admits that it can not be absolutely proved. It is supported by Stintzing's finding that the cerebrospinal fluid is toxic in tetanus and produces the disease by inoculation while the blood appears not to be. He gives a complete list of all cases of antitoxin treatment of tetanus that he has been able to collect and quite a lengthy bibliography of the later papers on the subject.

34. See abstract in The Journal xxxiv., p. 1259.

36 Excision of the Shoulder-Joint.—The method here described by Binnie consists first in exposing the joint by Ollier's method, then abducting the arm and have the assistant hold it at nearly a right angle to the axis of the trunk. From a point one-half inch below the clavicle and beside the coracoid he makes an incision four and one-half to five inches in length downward and outward toward the insertion of the deltoid, dividing the skin and subcutaneous tissue. Distinguishing the outer border of the deltoid he incises the deltoid a little to the outside of and parallel to its internal margin, thus avoiding injury to the cephalic vein and large branch of acromiothoracic artery. He then retracts the outer side of the wound and exposes the head of the humerus. Step 2. Rotate the arm so as to show the bicipital groove; incise the joint capsule throughout its whole extent parallel and external to the bicipital tendon. Place a chisel in position against the outer margin of the bicipital groove and cut the great tuberosity apart from the shaft. Reflect outward this detached shell of bone with all its connections, both tendinous and periosteal. Lift the long head of the biceps outward after freeing it from its synovial sheath. With the chisel cut the lesser tuberosity free from the shaft of the humerus and retract inward with its connections and through the long head of the biceps. Deflect the head of the humerus into the wound, at the same time severing its posterior attachments with elevator or scissors as usual. The rest of the operation is completed in the usual manner, the shells of the bone left are inspected and if diseased removed, otherwise replaced. In replacing, one or two points of suturing are used, uniting their non-osseous connections, and they should be so placed as to keep the long head of the biceps superficial to them. He claims his operation is so simple and saves so much time that he believes it is worthy of being offered to the profession.

40. Bacillus O.—Cushing describes cases in which a bacillus intermediate between the typhoid and colon types seems to be responsible. He has studied this organism thoroughly and gives results. It belongs to the group with the morphology of B. typhosus, but with alkaline milk-reaction, gas-producing with glucose and often distinctly pathogenic to man and animals. Its fermentative reactions, the results of inoculation, etc., are all elaborately worked out.

52. Fracture of the Patella.—Beck operates for this injury when separation of the fragments occurs, by inserting silver wire sutures around the parts to bring them together, insisting especially on the strength of these; they should be larger than will go through an ordinary needle. They should pass through the quadriceps tendon and ligamentum patellæ. The skin incision should be of semilunar form and go directly over the ligamentum patellæ from one epicondyle to the other, thus forming a convex flap which can be reflected backward. It is not necessary to touch the wound at any time with the fingers. The needle can be held with a needle-holder, and the wire ends twisted with the forceps and blood-clots washed out by an irrigation stream. The skin suture should be made with boiled formalin catgut, and a simple bandage applied or a fenestrated plaster splint. The wire can be removed through the fenestrum in about five weeks. The patient should still be kept quiescent for a week longer and then allowed to move cautiously.

56. This article has appeared elsewhere. See The Journal, xxxiv, p. 1451.

58 See abstract in The Journal of July 7, p. 51.

60. See Ibid.

64. **Nasal and Postnasal Synechiae.**—In this article Price-Brown treats of the subject of fibrous, bony or cartilaginous bands that unnaturally connect together the opposite walls of the nasal and postnasal cavities. They are most frequent between the middle turbinate and septum; next between the inferior and the septum. In the nasopharynx the synechia is usually found connecting the lip of the one or other of the Eustachian tubes, or some part of the pharyngeal vault. Their causes are, he believes, always traumatic, either directly or indirectly. The electrocautery or galvanocautery is amongst surgical causes the most prominent. They are due also to prolonged existence of turbinal hypertrophy, and sometimes no history can be traced, but close inquiry generally reveals reason for their origin. Special types of them are noticed and the prognosis is best when the cavity is wide in which the synechia is formed. He has found the saw the most useful instrument in their treatment, and to keep the parts open he uses cotton-wool tampons soaked in albolene. In fibrous cases the knife or scissors are the most useful. The hemorrhage that occurs at the operation is, he thinks, an advantage.

67. **Thrombosis of the Coronary Arteries.**—Rothrock reports two cases of thrombosis of the coronary arteries, and gives a general discussion of the subject as it has been developed in the literature of this country and elsewhere. In neither of these cases did the thrombosis entirely occlude the vessel, but in both it was well organized, suggesting slow formation, and death occurred during exertion, which is to be explained by the sudden strain put upon the heart. The cause of the sudden deaths is discussed and the author thinks that these cases probably belong in the category of angina pectoris. In one there has been previous angina attacks. In regard to the diagnosis there is nothing characteristic, but as the disease has been invariably fatal this is not so important.

69. **Suppuration Following Traumatism.**—Dugan reports the case of a man who was bruised by being thrown from a wagon, but was not aware of any head injury occurring. Later a suppuration developed from a fracture on the external and internal tables, discovered by operation. The curious fact about the case was that the man was bald, but had no mark on his head to show the injury. Recovery was uneventful.

72. **Spasmodic Spinal Curvature.**—A case of hysterical spinal curvature is here reported by Gillette, who discusses the diagnosis. Lack of pain in walking, no organic change in the vertebræ, even after years of mal-position, differentiated it from Pott's disease. Rigidity of the spine and muscles was the only condition which could possibly suggest spasmodic paralysis. There was only one long curvature instead of the double curvature, and not the rotation of the vertebræ existing in true lateral curvature.

73. **Sciatica.**—Sneve recognizes three types of what is generally called sciatica: true neuritis, perineuritis, myositis. The former is generally caused by some general infection or a toxin, or from compression from a tumor or growth. Perineuritis is probably due to the same cause that produces inflammation in the aponeurotic structures elsewhere in the body, such as gout, rheumatism, etc. Myositis is due to cold or hard muscular over-strain. True sciatic neuritis, he believes, is recovered from in from six months to two years, according to the amount of injury to the nerve. Perineuritis, which probably always includes neuralgia of the sciatic nerve, can usually be relieved in from one to six months, but it is very apt to recur. Myositis is usually recovered from in one to six weeks. Its pathology is not well known. The treatment of true neuritis is rest, with splints, hydrotherapy and anodynes. Perineuritis is treated by the same remedies as used for the ordinary condition of rheumatism, gout, etc., also local treatment in the way of the cautery, manipulation, etc., and he has used the method of stretching the nerve by external manipulation as a routine treatment. The sciatic-myositis he treats as a rule by the same methods as perineuritis.

82. **Treatment of Defectives.**—Makuen treats of the measures that should be taken to eliminate degeneracy, favoring state regulation of marriage, asexualization in certain instances, prison reforms, etc., educational improvements, etc. Preserving of the unfit has been so much the aim of the past that we have neglected the fact that they are reproducing and multiplying. He would look out for this by stringent marriage laws, removal of the power of procreation, and restriction of immigration.

83. **Specialism.**—This paper is the report of the committee of the American Academy of Medicine in regard to specialism, the general points of which are that it is not only unavoidable but is desirable and that it is proper for the physician to seek to perfect himself in the line of his greatest ability even to the neglect of other fields of practice. The specialist may practice directly, or indirectly through consultation, and in his ordinary practice he ought not to be an exclusionist. In his consultation practice the specialist stands in a different relation to his fellow physician from that of other general practitioners in consultation. He is rather a coadjutor than a consultant, and should follow the requisites of the family physician and not interfere with treatment until desired to do so. If a specialist limits his study to a particular branch because his aptitudes for that are of greater service to his profession, and carries into his limited practice the ethical principles of a doctor and gentleman, he can not be a cause of discord or trouble. When the physician should begin to limit his practice can not be settled as a rule. If his specialty requires operative skill he must begin early, but if he does not have actual experience in general practice he will fail to realize the importance of many things and be too much of an exclusionist. The report also takes up the subject of advertising, and holds that the first object of the physician should be the service to humanity, and next to this his duty to himself to make a living, but this order must not be reversed. Any method of advertising which only seeks to inform the public that the advertiser is ready to be of service, is admissible. The careful application of these principles will demonstrate the true character of any act on the part of the physician which calls the attention of the public to him.

84. **Exploratory Operations on the Spinal Canal and Cranium.**—Porter concludes that the opening of the spinal cavity and exploration of the brain and cord when properly done is accompanied by slight risk and is absolutely necessary in many cases before the diagnosis can be made. We should always remember that delay in diagnosis is often more dangerous than operation, and the rule should be about the same in like conditions of the abdomen. When in doubt, open and examine with the assurance that the possibilities for good far outweigh the possibilities for harm.

87.—This article was appeared elsewhere. See The Journal of July 14, lxxxix, p. 123.

88. **Twentieth Century Medicine.**—Hemmeter reviews the past and speculates somewhat on the future of medicine. He thinks that what we are to look forward to will be a greater development in certain lines, such as hygiene; the concentration of the population in cities will be discouraged; dwellings will be made more sanitary; the x-ray and other similar discoveries will be improved and enlarged upon and the state will control marriage relations for the general and individual welfare more than at the present time. He rather inclines to think that operative surgery has at least in certain lines reached its limit; surgery for carcinoma, for example, has no greater future, and that we must find out other methods of meeting this scourge through medicine and pathology.

90. **Myotherapy.**—The medical use of massage forms the subject of Herman's article. He thinks its usefulness is largely

limited to the afebrile conditions. It is indicated for the removal of exudates, infiltrations, to overcome stasis and improve local circulation, for the after-treatment of fractures, for the treatment of some forms of paralysis, correction of deformities and for a long list of ailments which this agent affects or benefits in a curative or prophylactic way.

91. **Bronchial Asthma.**—Swain studies the causes and pathology of asthma, rejecting the vasomotor theory and holding to the view of spontaneous contraction of nervous origin, of muscle fibers of the finer bronchioles causing congestion, so to speak, of the air in the vacuoles of the lungs. The reflex relations between nasal disease and bronchial asthma are discussed and he thinks the nose is only one of the factors in its causation. Asthma, he says, is a bronchial spasm brought on usually through certain exciting causes by the explosive neurotic condition of the nervous system. We should not, therefore, look for its cause in any single organ for the explaining of all attacks.

103. **Appendicitis.**—Lower believes the operation for appendicitis should be as soon as the diagnosis is made, if the surroundings are favorable, and if the patient has passed through one attack he should not be allowed to have a second, but an operation in the quiescent period should be performed. He thinks by operating in this period there is less danger to life, a shorter period of disability and smallest danger of complications.

104. **Convulsions in Children.**—Dickey's paper is a plea for the use of the cold bath rather than the time-honored hot one. In case of infantile convulsions he would methodically sponge the entire body or put the child in a bathtub with a temperature of 80 or 90 F., keeping up brisk friction in the meantime. An injection of cold water into the rectum will also be beneficial. During paroxysms chloroform can be justifiably used by an expert, not by the nurse. An enema will often bring away irritable matter and the stomach-tube may be useful in certain cases.

105. **Rubber Gloves in Surgery.**—Robb reports that it is only within the last year or two that he has learned to appreciate the advantages offered by the rubber sleeves, though he has been using the gloves for some five years. He attributes the favorable results in his operations largely to these appliances which relieve the physician of the embarrassment of the impossibility of thorough asepticizing the skin.

107. **Points in Surgery.**—The points alluded to are: An improved method of circumcision; a mnemonic device for remembering the nerve-supply of the hand; immobilization of the foot at right angles to the leg in cases of ankle injury; the value of the X-ray in hydrops ventriculi, and joint tuberculosis; phosphorus for rachitis; over-treatment of gonorrhea, and elimination of the surgical treatment for the majority of cases of varicocele.

119. **School Strain.**—This article is the discussion of a number of answers to queries sent out to teachers and others by the author, from which a rather remarkable variety of opinion was secured. One even went so far as to say that we can not make the average child study hard enough to harm it, and if some that are not average are injured what matters, the greatest good to the greatest number must be secured. Dr. King himself does not express a very positive opinion as to the reforms that are required, but he thinks it would be a good thing if medical men could inspect cases of children that seem to be suffering from the effects of school strain, at the same time informing the teachers, who would soon begin to realize the importance of the situation. As regards the question as to whether the boy or girl at and beyond puberty be required to do the same school work, King says that he would say "Yes," under certain conditions, viz., that the girl should be treated on the same conditions as boys, not sought to be made a lady of before her time.

121. **Typhoid Fever.**—Powers insists on the importance of more thorough disinfection in cases of typhoid so as to destroy the bacteria given off from affected persons. All their dejecta should be thoroughly sterilized with disinfectant solutions, all sewage should be sterilized before turning into any stream which may be used for any other purposes. No water should be used from a well located within 200 feet of any cesspool or vault, without having been boiled, and no typhoid fever patient or convalescent from typhoid should be allowed to be about any dairy or any place where milk or its products are marketed. All streams which supply water for domestic purposes should be thoroughly patrolled to prevent pollution.

127.—This article has appeared elsewhere. See The Journal, xxxiv, title 114, p. 1249.

134. **Physiology of Voice Production.**—According to Scheppegrell the difference in the use of the voice of singing and speaking is one of degree rather than kind. The average singer uses a greater range of pitch and the measure is more prominent than in speaking, as is also the length of the sustained vowel sounds, though both of these are present to a greater or less extent in the ordinary speech. The distinction between the classes of voices which we call soprano, mezzo-soprano, contralto, etc., is best expressed in the French term *timbre*, which refers to the difference that we observe, for example, between two instruments which may be of exactly the same tone and intensity, but differ in the character of the sound wave and not their rate of strength. In regard to the technique of voice production, the method of respiration plays the greatest part. He condemns the clavicular and lateral or costal method of breathing in singing; the abdominal or diaphragm method is the preferable one. Another point is the question of placing of the voice or adjustment of the larynx; the majority of singers with untrained voices use the larynx in the elevated position so that they do not get the full benefit of the re-enforcement of sound by the acoustic properties of the chest. The voice is a little softer, perhaps there is the gain of a few upper notes, but it is usually defective and weak. The same applies to speaking, and is the cause of the breakdown of many public speakers. It is largely learned by imitation by the child or youth about puberty, who follows the example of those about him. The speaking voice should be placed as low as the voice will permit so that it can be used without undue strain of the muscles or vocal cords and other muscles, and yet not so low as to prevent change in the inflections of the voice in giving expression to speech.

135. **Auricular Cataphoresis.**—From the results of experiments Ferreri concludes that under the action of an electric current the medicaments applied to the tympanic and mucous membrane of the cavity are not absorbed, and that galvanic cataphoresis is not an efficient resource in ear diseases. He admits his experiments do not justify absolute conclusions, but they show the necessity of further study.

136. **Physiologic Tests in Ear Lesions.**—Ballinger illustrates by cases the value of physiologic tests in the differential diagnosis of lesions of the ear, and while not claiming that the diagnosis can not be made without their aid, he believes that in many cases it will fail. While not of equal value with ophthalmoscopic examination of the fundus they are the best at the command of the otologist and should be used in combination with all other methods of differential diagnosis.

138. **Carbolic Acid in the Throat.**—Galloway reports a case where through an error or carelessness in labeling of the drug a 95 per cent. solution of carbolic acid was used as a spray for a man suffering from severe tonsillitis and pharyngitis. The mistake was recognized almost immediately, and equal parts of alcohol and water were applied by the same method and followed by mucilaginous drinks. The patient recovered in about a week, minus his tonsillitis.

The Lancet, August 4.

A Case of Meningomyelitis With Bacteriologic Examination of the Spinal Cord. George R. Murray and W. Hardcastle.—The authors describe a case of meningomyelitis apparently following exposure and exertion, and following the usual course, in which microscopic examinations of secretions of the cord showed the presence of what they recognized as a sort of oval motile bacillus, staining often most strongly at the ends and then resembling a diplococcus. It stained readily with aniline dyes and could with care be stained with Gram's method. It is found in large numbers in the pia and in lesser numbers in the substance of the cord. Pure cultures were obtained from both, and inoculation experiments showed it to be pathogenic to the guinea-pig and locally also to the rabbit. They report the case as bearing on the infective nature of meningomyelitis and refer to other cases in which somewhat similar findings have been recorded by Buzzard, Risien Russell and Trevelyan. They think the evidence goes a long way to show that acute disease of this character is probably infective, though it can not as yet be attributed to any single organism, but the bacilli that have been found in recorded cases have certain characteristics in common.

A Blood Reaction in Diabetes Mellitus; Its Cause and Diagnostic Value. R. T. Williamson.—The writer recalls that in 1896 he recorded a reaction which he believes to be peculiar to the blood of patients suffering from diabetes mellitus. A drop of blood taken from the finger decolorizes a warm alkaline solution of methylene blue when mixed in certain proportions, while the blood taken from healthy persons or from individuals suffering from other diseases has no such action. The reaction is due to the greater reducing power of diabetic blood, and is obtained as follows: At the bottom of a small narrow test-tube is placed a drop of water—40 cubic millimeters. To this is added 20 cubic millimeters of blood taken from the finger of a diabetic patient, then 1 c.c. of a watery solution of methylene blue, 1 in 6000, and finally, 40 cubic millimeters of liquor potassæ—B. P.—are added. Into a similar tube are placed 20 cubic millimeters of normal blood with the same proportion of methylene blue and liquor potassæ. The mixed fluids in the tubes will have a fairly deep blue or bluish-green color. Both these tubes are placed in a beaker or very wide test-tube containing water. The water is heated and kept boiling for four minutes; at the end of this time the fluid in the small test-tube containing the diabetic blood will have lost its bluish color and become a dirty yellow, while that in the tube containing the non-diabetic blood will remain bluish-green. He has examined blood in many cases of diabetes and always obtained a reaction, and has never obtained it in any other condition. His results have been confirmed by investigators in Germany, Italy, France, and America. Its reaction is due to some substance in solution in the blood-cells and is lost after the blood has been submitted to the action of yeast, the fermentative action of yeast fungus seeming to destroy the reaction substance. After the proteids of the diabetic blood or serum have been separated by boiling with crystalline soda sulphate and filtered, the filtrate gives the methylene blue reaction, but with the non-diabetic blood this fails. The action of the yeast is the same after the separation as before. It is well known that glucose has the power of reducing the warm alkaline solution of methylene blue and this methylene blue reaction carried out with the proportion of blood as before stated may be obtained with a solution of glucose. This reaction is obtained with diabetic urine, diabetic blood, diabetic blood-serum, and with filtrate from diabetic blood when the proteids have been separated. All these fluids after the action of the yeast fail to give the reaction. This indicates that the methylene blue reaction given by the diabetic blood is due to the action of the glucose which it contains. This reaction may be of value in diagnosis and it would be of special use after death in certain cases where diabetes has not been recognized. He thinks it advisable when the blood is examined post-mortem to always take it from the internal jugular vein. Blood from this vein is not liable to be contaminated by other fluids during necropsy. It is possible that it may be found that this diabetic reaction may be made the basis of an easy method of estimating the amount of sugar in the blood.

The Etiology of Scurvy. W. E. Home.—The author discusses the cause of scurvy and notices certain facts which lead him to suggest that the initial lesion is the infection of the gums due to micro-organisms of decayed teeth. This infection is antagonized by lime-juice and fresh vegetables, which act as antiseptics, it being most apt to occur in time of hardship when cleanliness is less within our reach.

Limitations of Physical Methods in the Investigation of the Physiological and Psychical Phenomena of the Sight. F. W. Edridge-Green.—The author refers to a former paper in which he showed why it is not possible to correctly ascertain color perception if we ignore color names. His views on the perception of color are stated as follows: Light acting on the retina liberates the visual purple from the rods and a photograph is formed, the cones and optic nerve-fibers conveying the impression to the brain. He thinks that it has been shown that this visual substance can be used up by exercise of the sight, and mentions experiments for the demonstration of this. He believes the shortening of the spectrum is due to some defect in this visual substance, the visual substance, being decomposed by light, sets up, by chemical, electrical or some other physical action, impulses which are conveyed to the brain by cones and optic nerve-fibers in the retina. The whole impression being brought to the center of memory, different portions, color forms, size, luminosity, etc., are conveyed to the mind through distinct perceptive centers. In the case of color the different perceptive centers are only able to distinguish six different points of difference in the spectrum, which really presents millions. We, therefore, have for normal sight the hexachromic theory, which agrees with the fact that both blue and violet have been demonstrated to be primary. It also, he believes, explains the degrees and variations of color-blindness. Assuming that the perception center is smaller, fewer points of difference are seen. The phenomena of contrasts is explained by the view that color being a point of difference this becomes more marked on comparison. In addition to other points raised, the following *appear to him as objections to the so-called physical methods* of ascertaining the color perception of individuals: 1. The varying absorption of light by the media of the eye, which affects the variation of the color curve without in any way affecting the real color perception of the individual. 2. Hyperesthesia as to certain colors that exists in certain individuals. 3. Variation in the subject's ideas of color. He believes we must be very careful in examining a person by physical methods to see that we do not obtain results that are physical, chemical and electrical phenomena. Psychical phenomena when they exist can not be measured by the balance and rule, but must be gained by direct evidence from the mind itself.

The Practitioner, August 4.

Recent Experimental Contributions to the Pathology of Diabetes. John Rose Bradford.—The fundamental fact in the pathology of diabetes is excess of sugar in the blood, and the method of producing this condition may be theoretically in three ways: 1. Too great an ingestion of sugar. 2. Excessive formation of sugar. 3. The presence of an excessive quantity may be caused by the tissues not oxidizing in the normal manner the amount normally ingested or produced. Probably most pathologists will agree in considering glycosuria and diabetes as possibly dependent on any one of these three conditions. Some, however, might hold the view that there is a fourth way, viz., owing to the peculiar disintegration of tissues, more especially the proteid tissues of the body, which are of such a character that they break down into nitrogenous and non-nitrogenous portions, the former excreting as a urea, the latter causing formation of sugar. According to this view, which is by no means generally held, diabetes might be unconnected with any anomaly in the ingestion, production, or destruction of sugar, but be really dependent on the primary disintegration of the tissues with sugar formation. The first view, that diabetes depends on the anomalies in the absorption of sugar is based on various observations of so-called alimentary glycosuria, but it is possible, however, that some of these may have a totally different origin and be really dependent on toxic actions. At the present time the bulk of cases, are considered to be of either hepatic or pancreatic origin. In the former case the production of sugar by the liver is greatly increased or the liver does not act as a sugar or carbohydrate stopping substance. The mechanism of pancreatic diabetes is not so clear, but the theory of Lépine that the organ produces a so-called ferment which is essential to the metabolism of sugar is probably the simplest explanation. There are some confirmatory facts supporting this view, but it can not be considered proved. The recent observations by Tuckett seemed to show that the thoracic lymph during digestion contains a substance which will cause glycosuria and it is possible that normally the activity of this substance is neutralized or annulled by the internal secretion of the pancreas, which would explain some experimental facts that have been reported.

Glycosuria and Diabetes in Relation to Life Assurance. HECTOR MACKENZIE.—The mortality from diabetes seems to be steadily increasing throughout the world, hence its importance in life assurance. A routine examination is now required of every applicant for life assurance. It is a matter of great importance that it should be detected when it exists, and it is very desirable that the examiner should state both the test he has employed and the results observed. This would in many cases enable the chief medical officer to form some idea as to the value of the observation. It must be remembered that there are some persons who are inclined to misrepresent themselves as being in perfect health when applying for insurance and will attempt to prevent the detection of glycosuria by special diet. The family history must be carefully looked into in this matter. Certain races, such as the Jews and Hindoos, seem to suffer more than others. Persons with red hair are supposed to be more susceptible to diabetes and tuberculosis and it is far more common in men than in women. Where both parents have died from the disease extra premium is certainly called for and such cases should be rejected, according to some authorities. If a small quantity of sugar is present the medical examiner should obtain a number of specimens without any restriction of diet. If no sugar is found in any of the other specimens and the life is not a young one and there is nothing else against it there is no cause for extra premium. Should there be a gouty history then the transitory glycosuria may be looked on as an additional reason for recommending the life for acceptance only as an endowment terminable at 63 or 65 as the case may be. If slight glycosuria is found on several occasions the applicant, if a young person, should be recommended to consult his own medical attendant and come up for examination on some future occasion. Cases of slight glycosuria in the middle-aged are not altogether ineligible, and, where it is associated with obesity and gout or both, may be considered as favorable on the whole. Cases of true diabetes, whether in old or young persons, should always be declined.

Clinical Tests for Sugar in the Urine. R. T. WILLIAMSON.—After describing the various tests for sugar in the urine Williamson concludes that the following rules are the best to follow in all contingencies: 1. Test with Fehling's solution, taking the precautions already mentioned—testing it for decomposition, keeping the amount of urine less than that of the solution, and not boiling too long. If the result be negative, no other test is required. 2. When Fehling's solution is reduced, but other indications of diabetes are absent, try the phenyl-hydrazin or fermentation test, or both. 3. When the reduction of Fehling's solution is slight, or when a decision is desirable within a few hours, try the phenyl-hydrazin test first. A negative result would be conclusive that the reduction of Fehling's solution was not due to grape sugar. 4. If the reaction with Fehling's solution is well marked, and if the decision can be conveniently delayed for a day, proceed at once to the fermentation test. A positive result is conclusive evidence of sugar. 5. Sometimes both confirmatory tests, and the testing of the urine with Fehling's solution after the action of yeast, are desirable, according to the indications already given.

Bulletin de l'Academie de Medecine (Paris), July 24.

Cure of Aneurysm by Ligature of Axillary Artery. GERARD-MARCHANT.—The aneurysm involved the entire right subclavian artery into the innominate trunk. It had developed in eighteen months to the size of a small hen's egg. A course of gelatin injections failed to benefit it, but the patient was completely cured after the axillary artery had been ligated under the clavicle and the common carotid tied close to the innominate trunk at the same sitting. This is the first time that ligature of the axillary has been successful, and the fact that the current in the artery was retarded, the pulse feeble, evidently contributed to the success. In less than six weeks the pulsating aneurysm had become transformed into a hard bunch.

Bulletin de la Soc. Med. des Hop. de Paris, July 19 and 26.

Pneumococcus Peritonitis. P. MENETRIER.—In fourteen cases of primary pneumococcus peritonitis collected by Brun, eleven were girls, but Menetrier has had occasion to observe four adult cases, including three males. All were fatal and offered no chance for surgical intervention. Two cases are described in detail. In one a peritonitis, commencing abruptly and without known cause, produced death in nine days. The diffuse purulent peritonitis found at the autopsy was without a trace of perforation, inflammatory focus or portal of entry for the infection. Cultures disclosed the pneumococcus and cadaveric flora. In the other, the peritonitis commenced suddenly in the course of a mild bronchial attack, possibly la grippe, and was distinguished by the three characteristic signs of pneumococcus infection, pain in the abdomen, vomiting and diarrhea. The abdominal phenomena then subsided and the temperature fell to 37 C., but the right foot developed a painful ischemia, with a gangrenous patch on one toe and ischemia of the hand, with visible and palpable thrombosis of the left radial artery, persistent albuminuria and diazo-reaction. The peritonitic symptoms reappeared the twenty-fifth day, accompanied by persistent and painful hiccough. The patient died in coma on the twenty-ninth day. The autopsy disclosed multiple arterial thrombosis and generalized peritonitis, with pneumococci developing in all cultures. There was no endocarditis nor intracardiac clot, nor source of emboli in the vessels or respiratory apparatus. The thrombosis must have been primary. The pneumococci were not found in the walls, but merely in the clot itself. Perimicrobian leucocytic agglomerations had probably formed in the blood from aborted phagocytosis, and as they increased in size had obstructed the circulation. Such phenomena are usually described as infectious arteritis, but the mechanism is probably that of a perimicrobian leucocytic thrombosis.

Action of Organs on Poisons. L. THOINOT.—The tissue of organs from freshly killed animals was mixed with poisons, passed through a filter and injected into other animals of the same species. The control animals were injected with the same poisons without mixture with the organs. The results showed that kidney and liver tissue neutralizes all poisons in variable degrees, while the tissue of other organs neutralizes some poisons and exaggerates the poisonous effect of others. Brain tissues, for instance, neutralizes morphin and strychnin; does not affect atropin but enhances to a marked extent the action of arsenic.

Echo Medical (Lille), July 29.

Hospital Abuses at Paris. THIERY.—Among the instances of hospital abuses cited by Thiéry in his address on this subject at the Congress of Professional Medicine, were the cases of a jockey receiving $5000 a year who applied at the Pitié for treatment of a sprain, and of a cashier on a $4000 salary who appeared with the other out-patients at the Hôtel Dieu and was surprised that he was not passed in first. The wife of a Bulgarian official who was sent to Paris for special treatment is another instance. She spent her money in the shops and had her laparotomy performed gratuitously at the Saint Louis. She did not even pay the small amount charged for a private room. This hospital had a similar experience with a woman who came from America for special treatment. A wealthy Russian prima donna requested to be operated on free of charge at her apartment, as "otherwise she would be compelled to go to a public hospital." One of the physicians of the charity out-patient department states that he has been summoned 337 times to attend persons who were not sick at all. He discovered that the cod-liver oil he had been prescribing for a child in another family was being systematically used to fill the lamps. Each year 18,000 out of the 50,000 births at Paris are at the public expense. Thiéry also called attention to the fact that each bed in the hospitals cost 20 francs a day, and that when less than this sum is accepted from well-to-do persons, the poor are deprived of the benefit of the balance.

Journal de Medecine de Paris, July 29.

Artificial Delivery with Glycerined Gauze. MAGNIAUX.—The writer describes three cases in which delivery was prematurely induced in women with narrow pelves, by means of a wick of glycerined gauze inserted into the cervix. He recommends the process as simple and within the reach of all, it obviates the danger of premature rupture of the bag of waters and of hemorrhage, and is more rapid in its effects than the Knause process, although not quite so sure. Even when it fails to induce delivery, it dilates the cervix, which facilitates the introduction of the sound or hystereurynter.

Presse Medicale (Paris), July 30 and August 1.

Cholera Infantum. A. B. Marfan.—Various experiments and tests are reported to prove that cholera infantum is due to an ectogenic intoxication caused by certain toxins which develop in milk during the first few hours after leaving the cow and are not affected by boiling the milk later. The toxins form much more rapidly in hot than in cold weather, and are the chief factors in the production of cholera infantum. The invasion of the intestinal mucosa by microbes is a secondary phenomenon. This conception emphasizes the necessity of sterilizing by the Soxhlet method or merely boiling the milk, when it can be done within two or three hours after milking. If several hours have elapsed, however, these methods of sterilization are absolutely useless, as they have no effect on the toxins already formed in the milk. If the milk has to be brought a long distance, it must be sterilized at the dairy within two or three hours. Marfan's treatment of cholera infantum is based on the suspension of all food and the administration of pure water, substituting the milk by approximately the same amount of water, and is attended by truly remarkable effects. Subcutaneous injections of artificial serum are also made, if indicated, and warm baths, with or without mustard, are given. If collapse seems imminent, he adds a little caffein to the artificial serum injected. The treatment after cessation of the choleriform symptoms is that of any simple gastroenteritis, returning again to the water diet if diarrhea reappears.

August 1.

Bacteriology of the Mouth of the New-Born. E. Bonnaire.—A case of double parotitis in an otherwise healthy new-born infant of a healthy mother, suggested bacteriologic investigation of the mouths of the new-born. Research on eighteen infants demonstrated that in every instance when the head of the fetus is lodged in the cervicovaginal canal for any length of time, after the rupture of the bag of waters, micro-organisms are found in the mouth, even in the absence of any digital exploration or intervention. The infection does not come from the outer air nor from the mother's nipple, but occurs during the passage of the head through the vagina unless the expulsion of the fetus is rapid and immediately follows the rupture of the amniotic sac. The membranes sometimes protrude and form a protecting sheath, isolating the entire inner surface of the vagina. In a subsequent case the vagina was rendered absolutely sterile as labor commenced, and during expulsion the genital zone was frequently irrigated with a solution of sublimate. As soon as the mouth appeared it was wiped with a sterile compress and a pad was kept over the mouth until the infant was placed in the incubator. No cultures could be obtained from the mouth six hours later.

Deutsche Medicinische Wochenschrift (Leipsic), July 26.

Tumors in Cerebellum. Schede.—A case is described in which the symptoms indicated a lesion in the cerebellum. The hearing was entirely lost in the left ear, and reduced to nearly zero in the right; vision, in left 20/300, and right 20/70. White and blue were the only colors distinguished; red was seen as black, green and yellow as white. There was also incipient optic atrophy and retrogressing congestion of the papilla. When the patient stood still he swayed, and when asked to turn around, fell immediately, swaying and falling always toward the left. The arm on this side was also weaker than the right. In operating, when the dura was exposed on both sides, the right seemed cyanotic, the left normal, but nothing was found on the right side, which was investigated first. The tumor was found 1 cm. below the surface in the left side, a glioma 2x4 cm. in size and weighing 18 gm. After its removal the X incisions in the dura on each side were easily sutured, leaving a gauze drain on the left. The results were brilliantly successful. By the next day the hearing was practically restored to normal and the sight was much improved. The patient can now count fingers readily. The swaying also ceased. In a second case the symptoms were still more pronounced. The patient swayed and fell constantly to the left. A smooth-walled cyst was found and removed on the left side, but it proved to be only a portion of a cystic glioma, which entailed death within a month. No blood was lost during either operation, which Schede ascribes to the erect sitting posture of the patients, with merely the head bent over. The first operation increases to 3 the number of patients cured by removal of a tumor in the cerebellum out of 14 operated on. Five died immediately; three survived without improvement, and one died from recurrence. Schede made a semicircular incision from one mastoid process to the other and dissected down the soft parts in a flap reaching to the bone and downward to the foramen occipitale magnum. Removing the crista occipitalis allows ample space for removal of a tumor. The bone defect at this point is of little moment, as the strong muscles of the neck cover it sufficiently.

Parasitic Nature of Eczema. W. Scholtz.—The writer confirms his previous announcements that eczema is due to the action of the staphyloccus pyogenes aureus on a specially prepared soil, the nature of the preceding alteration of the epithelium and corium determining the eczematous character of the dermatitis, in connection with individual peculiarities and especially the susceptibility of the skin. This conception explains the empiric success of present methods of treatment.

Early Diagnosis of Carcinoma. E. Hollander.—In examining the patient for evidences of carcinoma hereditary antecedents are of the greatest value, especially in case of carcinoma of the alimentary canal. There are families in which the lungs, in others the stomach, etc., are the *locus minoris resistentiæ*, but in scarcely any other affection is this family tendency so marked as in carcinoma of the intestines. Hollander refers to one family in which there were 16 certain cases and 3 dubious in five generations. He also calls attention to the fact that in studying the family history it must be borne in mind that if members of the family die under 40 this by no means excludes the possibility that they might have had carcinoma later, in which respect it is in marked contrast to tuberculosis. Another diagnostic point is certain alterations of the skin, which seemed to accompany intestinal carcinoma with striking frequency. They are three-fold; vascular, verrucous, or pigmentary, and usually occur more or less pronounced, and possibly associated. The vascular alterations are numerous bright-red spots in the midst of sound skin the size of a pinhead to that of a bean, slightly raised above the level of the surrounding skin. Pressure does not expel the blood unless forcible. They occur even on the obese and in fatty regions of the body. The second cutaneous anomaly is the seborrhagic warts, such as are known as senile warts, but which occur in young persons with the carcinoma tendency. In some cases they develop into tumors which only differ from other carcinomata of the skin by their relative benignity. The third group is the pigmented patches, resembling freckles, which are scattered more or less numerously over the covered portions of the body. In a case illustrated, the entire thigh is spotted like a bird's egg. The sister of this patient had exhibited the same cutaneous phenomenon as a premonitory symptom of intestinal carcinoma, and the second patient diagnosed her own carcinoma long before the physicians could discover it.

Sale of a Medical Practice. Biberfeld.—A suit has recently been decided in Germany relieving the incoming doctor of the obligation to pay a certain amount for the medical practice of his predecessor. The sale of a medical practice was qualified by the judge as immoral—*gegen die guten Sitten.* Biberfeld protests against this view and presents arguments to prove its fallacy, unless the practice is sold knowingly to a charlatan or man of irresponsible character.

Muenchener Medicinische Wochenschrift, July 24.

Autointoxication and the Thyroid. F. Blum.—The title of this article in the original is "New experimentally discovered ways of determining and treating diseases induced by autointoxication." After much experimental research Blum asserts that the function of the thyroid is to deprive of their toxicity the toxins generated in the intestinal canal from the putrefaction of albumin. If the thyroid gland is not working properly these enterotoxins are not rendered innocuous and consequently pass on unchanged and cause serious disturbances, with corresponding anatomic changes. If the action of the unneutralized enterotoxins is sudden and stormy, the central nervous system is alone affected, but if prolonged, the kidneys exhibit evidences of degeneration in the parenchyma, and interstitial proliferation and infiltration in the vicinity of the glomeruli. The enterotoxins in their passage through a healthy thyroid gland are deposited there as a highly molecular combination—thyreotoxalbumin—and are gradually deprived of their toxicity. The combination hitherto supposed to be the specific iodin-substance of the thyroid gland is in reality merely an intermediate product of this transformation process. It is, in short, a thyreotoxalbumin more or less saturated with iodin. This thyreotoxalbumin never passes into the circulation if the thyroid gland is sound, and there is also a pre-existing and acquired immunity against it. There is likewise formed in animals restored to health after thyroidectomy a substance that protects against the enterotoxins. Immunity against enterotoxins does not confer immunity against the thyreotoxalbumin nor vice versa. If the results of this research apply also to man, they suggest that many more diseases than have hitherto been supposed, are closely connected with intestinal processes and insufficiency of the thyroid gland. They would modify our previous conceptions of myxedema and of Basedow's disease, and indicate therapeutic measures.

Present Status of the Sanatorium. E. RUMPF.—The writer is in charge of a large sanatorium in Baden and he deplores the loss of time and expense from the carelessness that sends absolutely incurable consumptives to such institutions. Polyclinics for tuberculous patients will be a great assistance in this line, especially if they are conducted by men with practical experience as medical attendants in a sanatorium, but most desirable of all would be a special tuberculosis hospital in the larger cities, to relieve the general hospitals, in which the patients could be sifted out and the internes trained.

Expiration Grooves in the Liver. K. WALZ.—The sagittal grooves on the upper surface of the liver have been explained in various ways, but the writer demonstrates that they are caused by the bending of the organ as the diaphragm presses down the upper surface and then releases it. The middle is pressed down and the sides up, and then the sides relax in expiration and the middle rises. The process is probably an important factor in the evacuation of the gall-bladder.

Improved Technique of Hand Disinfection. B. KRÖNIG.—Zweifel has been using for several months a solution of mercury which he considers much superior to sublimate, as with identical disinfecting powers it has no irritating action on the skin, does not precipitate albumin nor blood, while it has a much more intense deep action, at least on dead tissues. The salt used is the citrate of mercury, 10 gm. with ethyl diamin 4 gm., and water 86 gm. It is used in a 3 per 1000 solution and in place of the 1 per 1000 sublimate, after eight to ten minutes' scrubbing.

Therapie der Gegenwart (Berlin), July.

Treatment of Impotency. E. MENDEL.—Besides the usual measures and remedies in vogue, Mendel has been using during the last two years yohimbin, a medicine borrowed from the natives of Cameroon, where it is used to cure impotency in the male. Tests on dogs showed that it possessed an unmistakable effect on the genital sphere, which larger doses intensified into general convulsions. It had also a paralyzing tendency later, and depressed the pulse. He has treated forty cases of impotentia coeundi with sol. yohimbini, 5 to 10 drops, three times a day. A distinctly favorable effect was evident in 50 per cent. of the patients who could be controlled, and no injurious effects of any kind followed its administration. Mendel adds that even assuming that suggestion may have had something to do with the results, they still warrant further trials of the remedy. When he suspects hypochondriac functional impotency in a member of the "upper ten" he finds that a bottle of champagne is usually sufficient to suppress the inhibiting influences.

Gazzetta degli Ospedale (Milan), July 12 and 29.

Vitality of Skin Flaps. P. PEZZOLINI.—The extreme limit of latent vitality in the experiments with periosteum flaps, reported by Grohé and Morpurgo last year, never surpassed 100 and 192 hours, respectively. Pezzolini's grafts of skin taken from the backs of dogs and kept in normal salt solution at room temperature, were successful even after an interval of six days. In other similar experiments some of the cells showed mitosis after a ten-day interval, and even after eleven days when kept at zero temperature. Experiments with similar flaps sealed dry in a glass jar kept in the refrigerator, demonstrated that they rapidly lost their vitality within two days, when dry. The flaps in the successful grafts grew into place by the same mechanism as fresh flaps, only more slowly and with greater loss of tissue.

Sclavo's Serum for Pustula Maligna. A. LISCIA.—In many years' experience with pustula maligna, all the mild cases recovered, no matter what treatment was used, and all the malignant ones died. In two recent cases of unmistakable malignant character both were saved with the prompt administration of Sclavo's serum.

Hysteric Cutaneous Lesions. E. LEONARDI.—A placid well-developed young Italian woman was affected at periods corresponding to the menses with a suddenly appearing elliptic solution of continuity on the lower eyelids and on the nasolabial sulcus, which healed without a scar in a few days. There was not a trace of hysteria about the girl or her antecedents, except the facility with which she could be hypnotized and the presence of two anesthetic zones on the forearm and right cheek. Leonardi, however, is inclined to attribute the lesions to a hysteric autosuggestion from a patch of preceding eczema on the girl's hand and forearm.

New Conceptions of Helminthiasis. P. DEMATTEIS.—For a number of years Dematteis has been studying and experimenting with intestinal worms. He noted that in a number of cases of typhoid fever the patients evacuated ascarides by mouth and anus, and he has succeeded in demonstrating that a febrile elevation of temperature arouses the helminths and especially the nematoda to increased energy of movement. Owing to this increased energy, they may produce trauma of the intestinal walls and consequent lesions, particularly if the fever is associated with conditions of the walls rendering them more susceptible to injury. His recent observations and tests have also established that helminths secrete toxic substances which may determine various morbid processes when absorbed. He found in the intestines of ascarides taken from six children the bacillus coli, subtilis, proteus, and various staphylococci and streptococci. In one case there was a pure colony of the latter. There is, therefore, great danger from evacuation of pathogenic germs and elaborated toxins in helminths migrating under the influence of febrile temperatures, especially if there are anatomopathologic alterations in the intestinal walls. This subject is one that deserves the consideration of all physicians and appropriate measures to exterminate the helminths in all such cases where their presence is suspected.

July 29.

Diastatic Ferment in White Corpuscles. C. TARCHETTI.—Dogs were injected subcutaneously with a solution of rice starch and the corpuscles examined later in respect to their reaction to iodin. Some of the whites presented a typical reaction in the granules of starch, while in others there was unmistakable evidence that the starch had undergone partial digestion in them. In another experiment insoluble starch left for seven days in contact with sterile pus at a temperature of 37 C. became soluble. Sterile pus dried and pulverized, and mixed with alcohol and glycerin, was also found to have a marked diastatic action on starch.

Treatment of Syphilids During Pregnancy. N. FEDERICI.—As a contribution to the disputed problem of the advisability of energetic mercurial treatment during pregnancy, Federici relates an observation of a young woman in the eighth month of pregnancy who applied for relief from a specific iritis. She presented a characteristic roseola and diffuse adenopathy. Certain physicians consulted hesitated to institute the treatment indicated, but Federici ventured on a vigorous course of mercurial injections, accompanied by potassium iodid, with the satisfactory result of curing the syphilids without interfering with the normal delivery at term of a "fine boy."

Brazil Medico (Rio Janeiro), July 1.

Excision of Buboes in Plague. Camillo Terni.—It is an unpardonable error to wait for the suppuration of the bubo before excising it, according to Terni. The infection rapidly spreads and its toxic effects soon become manifest, while serum treatment is powerless at this stage. *Excision of the primary* bubo will frequently arrest the infection and should never be neglected. It is a simple operation. The bubo is easily isolated and excised with the contiguous lymphatic ganglia, especially if they are hemorrhagic. It is seldom necessary to apply a ligature, and the loss of blood is slight. The region is then irrigated with a strong solution of sublimate and a moist drain inserted. He advocates local anesthesia with ethyl chlorid, and recommends excision of the bubo even in doubtful cases, as it can never do harm. If excision is absolutely impossible, he recommends injecting a 2 per cent. solution of sublimate or of phenic acid into the bubo. In his experiences at the Jurujuba Hospital in April and June, 37 died out of the 45 plague patients received, a proportion of 26.2 per cent. Excluding those who died in less than forty-eight hours after entering, the proportion is only 13 per cent. The thirty-six cases in the town during the same thirty days, who were treated by other methods at home or received no treatment, proved fatal.

Ichtheroid Psychoses. M. Néry.—Certain writers have tried to distinguish a special variety of mental disturbances which occur consecutive to yellow fever, but Néry asserts that they do not differ in any respect from the various psychoses observed during convalescence from any infectious disease.

St. Petersburger Medicinische Wochenschrift, July 14, 21 and 28.

Success of Mercury in Gonorrhea. A. Paldrock.—A patient had been long treated in vain for chronic articular rheumatism, which had first commenced about a year after a tedious but finally cured gonorrhea. Inspired by Böttcher's success with a case of general gonorrheal infection cured with gray ointment, Paldrock commenced a course of inunctions, and after 144 gm. had been rubbed into the patient in the course of five weeks, he was dismissed, completely cured, and has had no recurrence during the year since. In another case of chronic gonorrhea the cocci were found in the effusion of an intercurrent pleurisy. The writer concludes by suggesting that multiple articular affections with chronic, acute or past gonorrhea should be treated with gray ointment even in the absence of syphilitic antecedents. Gonorrheal articular affection is characterized by the rapid involvement of the ligaments and the small amount of exudate. Contraction, atrophy and ankylosis appear early. Such cases are by no means rare, but they usually masquerade as "chronic articular rheumatism."

Puerperal Eclampsia. G. Ferberg.—The writer of this communication distinguishes between hysteric, epileptic and eclamptic puerperal convulsions. In a recent case the seizures that occurred during the puerperium suggested epilepsy, although there had been no previous history of anything of the kind. A sister had been affected in the same way; both women died in a few days after delivery. The cases suggest the existence of latent epilepsy in each, aroused to activity by the stress of parturition.

July 21 and 28.

Syphilis Hemorrhagica Neonatorum. W. Loewenberg.—Three observations of hemorrhagic diathesis in the new-born with severe inherited syphilis are described. Bacteriologic tests in each case revealed the presence of streptococci or staphylococci in the blood and conclusively demonstrated a septic infection. The writer also reviews the cases on record and concludes that there are no grounds for assuming the existence of a specific hemorrhagic syphilis in the new-born.

Books and Pamphlets.

Acknowledgement of all books received will be made in this column, and this will be deemed by us a full equivalent to those sending them. A selection from these volumes will be made for review as dictated by their merits, or in the interests of our readers.

BOOKS.

A Dictionary of Medicine and the Allied Sciences. Comprising the Pronunciation, Derivation, and Full Explanation of Medical, Pharmaceutical, Dental and Veterinary Terms, Together with Much Collateral Descriptive Matter, Numerous Tables, Etc. By Alexander Duane, M.D., Assistant Surgeon to the New York Ophthalmic and Aural Institute. Third Edition. Enlarged and Thoroughly Revised. With Eight Full Page Colored Plates. Cloth. Pp. 645. Price, $3.00. Philadelphia and New York: Lea Bros. & Co.

Atlas and Epitome of Special Pathologic Histology. By Docent Dr. Hermann Duerck, Assistant in the Pathologic Institute; Prosector to the Municipal Hospital, L.I., in Munich. Authorized Translation from the German. Edited by Ludvig Hektoen, M.D., Professor of Pathology in Rush Medical College, Chicago. Circulatory Organs; Respiratory Organs; Gastrointestinal Tract. With 62 Colored Plates. Cloth. Pp. 158. Price, $3.00. Philadelphia: W. B. Saunders. 1900.

A Manual of Surgical Treatment. By W. Watson Cheyne, M.B., F.R.C.S., F.R.S., Professor of Surgery in King's College, London, and F. F. Burghard, M.D, and M.S., F.R.C.S. Teacher of Practical Surgery in King's College, London. In Seven Volumes. Volume iii. The Treatment of the Surgical Affections of the Bones. Amputations. Cloth. Pp. 305. Price, $3.50. Philadelphia and New York: Lea Bros. & Co. 1900.

A Manual of Clinical Diagnosis by Microscopic and Chemical Methods. For Students, Hospital Physicians, and Practitioners. By Charles E. Simon, M.D., Late Assistant Resident Physician, Johns Hopkins Hospital, Baltimore. Third edition, thoroughly revised. Illustrated with 136 Engravings and 18 Plates in Colors. Cloth. Pp. 558. Price, $3.50. Philadelphia and New York: Lea Bros. & Co. 1900.

Clinical Studies in Epilepsy. From the Craig Colony for Epileptics at Sonyea, N. Y. 1. Exhaustion-Paralysis in Epilepsy. 2. Paramyoclonus Multiplex Associated with Epilepsy. 3. Hypertrophic Infantile Cerebral Palsy and Phocomelus Associated with Epilepsy. L. Pierce Clark, M.D. Paper. Pp. 230. Utica, N. Y.: State Hospital Press. 1900.

Beneath Hawaiian Palms and Stars. By E. S. Goodhue, Government Physician. Illustrated from Photographs and Pen Sketches by Robert J. Burdette, Jr., and C. B. Andrews. Cloth. Pp. 248. Price, $1.50. Cincinnati, Ohio: The Editor Publishing Co.

Second Report of an Investigation of the Rivers of Ohio as Sources of Public Water Supplies. By the Ohio State Board of Health. 1899. Cloth. Pp. 284. Columbus, Ohio: The Westbote Co. 1900.

Thirteenth Annual Report of the State Board of Health of the State of Ohio for the Year Ending October 31, 1898. Paper. Pp. 689. Columbus, Ohio: The Westbote Co. 1899.

Ringworm in the Light of Recent Research. Pathology, Treatment. Prophylaxis. By Malcom Morris, Surgeon to Skin Department, St. Mary's Hospital. With Twenty-two Microphotographs and One Colored Plate. Cloth. Pp. 137. Price, $2.00. London, Paris and Melbourne: Cassell & Co., Ltd. 1898.

Forty Years in the Medical Profession, 1858-1898. By John Janvier Black, M.D., Member of the College of Physicians of Philadelphia. Cloth. Pp. 498. Price, $3.00. Philadelphia: J. B. Lippincott Co. 1900.

On Gall-Stones and Their Treatment. By A. W. Mayo Robson, F.R.C.S., Professor of Surgery in the Yorkshire College of the Victoria University. Illustrated with 20 engravings. Cloth. Pp. 285. Price, $2.00. London, Paris and Melbourne: Cassell & Co., Ltd. 1892.

A Treatise on Appendicitis. By John B. Deaver, M.D., Surgeon-in-Chief to the German Hospital, *Philadelphia*. Second Edition. Thoroughly Revised and Considerably Enlarged. Illustrated with Twenty-two Full Page Plates. Cloth. Pp. 300. Price, $3.50. Philadelphia: P. Blakiston's Son & Co. 1900.

Transactions of the American Association of Obstetricians and Gynecologists. Vol. xii. For the year 1899. Cloth. Pp. 365. Philadelphia: Wm. J. Dornan. 1900.

Twenty-third Annual Report of the Board of Health of the State of New Jersey and Report of the Bureau of Vital Statistics. 1899. Cloth. Pp. 432. Trenton, N. J.: MacCrellish & Quigley. 1900.

A Memoir of Henry Jacob Bigelow, A.M., M.D., LL.D., Member of Massachusetts Medical Society, Etc. Cloth. Pp. 297. Price, $4.00. Boston: Little, Brown & Co. 1900.

I. The Mechanism of Dislocation and Fracture of the Hip. II. Litholapaxy; or, Rapid Lithotrity with Evacuation. By Henry Jacob Bigelow, A.M., M.D., LL.D. Cloth. Pp. 356. Price, $4.00. Boston: Little, Brown & Co. 1900.

Surgical Anesthesia Addresses and Other Papers. By Henry Jacob Bigelow, A.M., M.D., LL.D. Cloth. Pp. 375. Price, $4.00. Boston: Little, Brown & Co. 1900.

Orthopedic Surgery and Other Medical Papers. By Henry Jacob Bigelow, A.M., M.D., LL.D. Cloth, Pp. 373. Price, $4.00. Boston: Little, Brown & Co. 1900.

Dr. W. B. Ray, from Etna to Box 148, Glenshaw, Pa.

Dr. L. S. Ramsdel, from 489 E. 42d St., Chicago, to Manistee, Mich.

Dr. Louise M. Richter, from Los Angeles to Garvanza, Los Angeles County, Cal.

Dr. J. E. Stanton, from St. Anthony Hospital to 829 Flournoy St., Chicago.

Dr. G. O. Switzer, from Greenland, Mich., to Stanley, Wis.

Dr. J. H. Spencer, from Fayetteville, Ark., to Berlin Building, Tacoma, Wash.

Dr. C. E. Sayre, from 103 State St. to 122 LaSalle St., Chicago.

Dr. F. D. Smythe, from 269 Vance St., to Porter Bldg., Memphis, Tenn.

Dr. W. L. Taylor, from Townesville to Storall, N. C.

Dr. J. Titcomb, from 327 Providence St. to New Jersey Bldg., Duluth, Minn.

Dr. J. R. Taylor, from Kenosha, Wis., to 246 3rd Ave., Detroit, Mich.

Dr. Edward Wallace Lee, from Omaha, Neb., to Lineman Bldg., Vandeventer and Washington Boul., St. Louis, Mo.

Dr. J. F. Wilson, from 6124 Sangamon St. to 535 W. 61st St., Chicago.

Dr. R. H. Whittington, from New Matamoras to West, Ohio.

Dr. J. M. Wallace, from Tallassee, Ala., to Webster, Fla.

Dr. W. G. Wren, from 713 Mt. Vernon Ave. to 225 North Ohio Ave., Columbus, Ohio.

Dr. A. N. Yates, from Boulder to Lyons, Col.

Queries and Minor Notes.

MEDICAL LAWS.

BURKESVILLE, KY., Aug. 14, 19

To the Editor:—Will you please do me the favor of publ in your next issue of THE JOURNAL, the laws in regard practice of medicine in the State of Washington, and State nessee, as they exist at present. Fraternally, A SUBSCR

ANS.—For the Washington law see THE JOURNAL, Aug In Tennessee, unless the applicant is a graduate of a med lege within the state, an examination is required. For application, etc., address T. J. Happel, M.D., Sec'y., Trento

To the Editor:—Please inform me through THE JOURN the laws regulating the practice of medicine in the States York and Connecticut, and give addresses of the secreta each state board of examination.

ANS.—In New York a candidate must be 21 years of a good moral character (certificate from two physicians in standing), and have a satisfactory preliminary education, h attended four courses of at least six months each in a recogniz medical school and pass an examination satisfactorily. The Secretary of the Board of Examiners is Dr. M. J. Lewi, Bowling Green Bldg., 5 Broadway, New York.

In Connecticut an examination is required. The Secretary of the State Board of Health is Dr. C. A. Lindsley, New Haven.

To the Editor:—Will you kindly give me what information you can regarding laws governing practice of medicine in Porto Rico Island and oblige? Yours truly, C. V. G.

ANS.—We are not fully informed as to the requirements for practice in Porto Rico. The correspondent is referred to Dr. J. VanR. Hoff, U. S. A., San Juan, for particulars.

"INHALATION OF GASEOUS ANTISEPTICS."

NASHVILLE, TENN., August 12, 1900.

To the Editor:—Can you tell me if Lacroix's article, "Inhalation of Gaseous Antiseptics," in *Bulletin de l'Académie de Médecine* (Paris), June 26, has been translated into English? If so, where can I get it? If not, where can I get the *Bulletin* in this country containing the article? There is an abstract of the article on page 325 of THE JOURNAL of the A. M. A. for Aug. 4, 1900. Very truly yours, L. B. G.

ANS.—We are not aware of any English translation of the article mentioned. The *Bulletin de l'Académie de Médecine* can probably be obtained directly from the publishers, Mason et Cie., 120 Boulevard Saint Germain, Paris, France, or through importing booksellers. If the French copy is desired it can be loaned from THE JOURNAL office on receipt of postage and promise to return.

"HYGIENE"?

BEDFORD, IND., Aug. 7, 1900.

To the Editor:—Can you send me the address of *Hygiene*, a journal devoted to that branch exclusively?

Yours respectfully, V. O.

ANS.—The only publication of the name known to us is published in London, England. It does not appear, however, in the list of English medical publications in Churchill's Medical Directory for 1900.

ILLITERATE DOCTORS.

The Indiana State Board of Medical Registration and Examination is trying to raise the standard whereby physicians are granted licenses in that state. That there is a crying need for this movement is evidenced by the following letter received by the Board from a would-be practitioner in a remote county:

"Dear Sir—Excuse me for [illegible] fooled by [illegible] Tis surely my understanding [illegible] Di [illegible] says. I have my tickets [illegible]

I paid and worked hard for that Diploma. I had work in all that is mentioned in that Diploma. Is the signature good to that Diploma. Will you please answere the above question. I only intended that for a Certificate of Obstetrics and I see in the Law that Obstetrical Diplomas are taking. I thought the application blank was hardly right. If you can give me a certificate for what that calls for send me a proper blank to fill out and return to you. The $5 I sent was correct with an Obstetrical Diploma. Now if you can't do nothing I have ask send my money and Diploma back and a application blank for Examination in January, The 2 Tuesday. The reason I am delaid in answering yours, etc."

The Public Service.

Army Changes.

Movements of Army Medical Officers under orders from the Adjutant-General's Office, Washington, D. C., August 1 to 7, 1900, inclusive:

William H. Arthur, major and surgeon, U. S. A., relieved from duty in San Francisco, Cal., to proceed to Taku, China, and report to Major-General Chaffee for assignment.

Robert E. Caldwell, acting asst.-surgeon, now at San Francisco, Cal., to report for assignment to the transport *Rosecrans*.

Henry R. Carter, jr., acting asst.-surgeon, now at Vancouver Barracks, Wash., to temporary duty at that post.

Edward T. Comegys, major and surgeon, U. S. A., former orders revoked, to proceed without delay to San Francisco, Cal., and report to the surgeon-general by telegraph for further instructions.

James J. Edmondson, acting asst.-surgeon, from Fort Du Pont, Del., to San Francisco, Cal., for assignment to duty with troops destined for foreign service.

Robert J. Gibson, major and surgeon, U. S. A., relieved from further temporary duty at San Francisco, Cal., and will report for assignment as attending surgeon and medical superintendent of the Army transport service in that city.

Randolph Harmer, acting asst.-surgeon, from Opelika, Ala., to Washington, D. C., to report to the surgeon-general for instructions.

mes J. Holloway, acting asst.-surgeon, from the transport ans, to the transport *Sheridan*.

on J. Hooper, acting asst.-surgeon, from duty on the transport *edgwick* to San Francisco, Cal., for duty with troops destined for foreign service.

ancis J. Ives, major and surgeon, Vols., from New York City to San Francisco, Cal., for duty with troops en route to China.

ames G. McKay, acting asst.-surgeon, from duty in the Division of Cuba, to report, on expiration of present leave of absence, at Fort Sheridan, Ill,, to accompany the 5th Infantry, under orders for foreign service.

Charles B. Mittelstaedt, acting asst.-surgeon, from New York City to San Francisco, Cal., to accompany troops en route to China.

Robert M. O'Reilly, lieutenant-colonel, deputy surgeon-general, U. S. A., relieved from the command of the Josiah Simpson General Hospital, Fort Monroe, Va., and will turn over the quartermaster's property, for which he is responsible, to Major William J. White, quartermaster, Vols., and dispose of the property of the medical department under instructions from the surgeon-general.

Ernest C. Schultze, acting asst.-surgeon, from New York City to San Francisco, Cal., to accompany troops en route to China.

George K. Sims, acting asst.-surgeon, relieved from duty in the Department of California for assignment with troops en route to the Philippine Islands.

George H. Torney, major and surgeon, U. S. A., to proceed to Battle Creek, Mich., and Richfield Springs, N. Y., on official business and to return to his proper station.

J. P. Truax, acting asst.-surgeon, leave of absence granted.

Benjamin F. VanMeter, acting asst.-surgeon, leave of absence granted.

Robert H. Zauner, acting asst.-surgeon, from Washington, D. C., to post duty at Fort Du Pont, Del.

The following acting assistant-surgeons have been directed to proceed from the place set opposite their respective names to San Francisco, Cal., to accompany troops destined for foreign service: William P. Baker, Guthrie, Okla.; Lewis F. Bleaseby, Detroit, Mich.; Frederick A. Dale, Lemont, Pa.; James F. Edwards, Slate Lick, Pa.; Graham E. Henson, St. Clair, Mich.; James F. Kemp, Washington, D. C.; James Kenan, New York City; Alvis B. Kennedy, Bonham, Tex.; Harry D. Kneedler, St. Louis, Mo.; William E. Lower, Cleveland, Ohio: Patrick McGrath, Washington, D. C.; David W. Overton, New York City; Louis W. Pease, Saginaw, Mich.; Harper Peddicord, Baltimore, Md.; Thornton W. Perkins, Catonsville, Md.; Joseph Pinquard, Vinita, Ind. Ter.; Ernest F. Slater, New York City; James W. Thornton, Ayrshire, Iowa; Gideon M. Van Poole, Salisbury, N. C.; George B. Wallace, Ann Arbor, Mich.; Francis M. Wells, Charlestown, Ind.; W. Turner Woolton, Catonsville, Md.

Navy Changes.

Changes in the Medical Corps of the U. S. Navy for the week ending Aug. 11, 1900:

Asst.-Surgeon C. A. Crawford, detached from the *Eagle* and ordered to the *Chesapeake*.

Asst.-Surgeon C. H. Delancy, detached from the *Constellation*, August 13, and ordered to the *Bancroft*.

P. A. Surgeon W. C. Braisted, detached from the *Massachusetts* and ordered to the *Topeka*.

Asst.-Surgeon W. M. Garton, detached from the Ne ordered to temporary duty on the *Massachusetts*.

DEATH.

P. A. Surgeon James Stoughton, U. S. N., was Shanghai, China, August 5. 1900.

Marine-Hospital Changes.

Official list of the changes of station and duties of and non-commissioned officers of the U. S. Marine-Ho for the 14 days ending Aug. 9, 1900.

Surgeon J. H. White, to proceed to Mullet Key Deten Fla., as inspector.

Surgeon L. L. Williams, to proceed to Stapleton, N. spector of unserviceable property.
